This test will show that any combined-bath prints, whether collodion or gelatine, will bleach first; much later, albumen prints will start to fade, after which comes the turn of collodion or gelatine papers toned in separate baths. Bromide prints stand the test longest, and change very little.

DR. LEO BAEKELAND.

THE ANASTIGMATIC SYMMETRICAL APLANAT.

[Photographisches Archiv.]

Starting from the construction of the human eye, in which nature has created an anastigmatic, wide-angle aplanat, I hit upon the idea of constructing a lens perfectly free from chromatic and spherical aberration and distortion, by using only two refractive substances.

The Zeiss anastigmats, in which three to six lenses of great thickness are used, appear to me a step backward, instead of forward, on the true path of progress in lens construction, not only on account of their high price, but also from great loss of light.

Should it not be possible to attain, with only two refractive media, that which the new combinations, with their three, four, and six lenses, have but striven to approach? If we examine the eye more closely, we see, first of all, that it is composed of nearly similar refractive media and negative and positive lenses, which, as a whole, have very little chromatic aberration; and this, as well as the refraction, differs very little for the crystalline lens and the surrounding humours.

Why, then, employ heavy kinds of glass of high dispersion, that increase astigmatism, the greater the difference, N – n, between the mean refraction of the flint and crown glasses?

1. The use of media of low refraction and dispersion recommends itself as a first principle in imitation of nature and the construction of the eye, for the reason, that astigmatism is eliminated as much as possible.

Combine a low dispersive, for example a phosphate glass, with a more dispersive but lower refractive crown glass. A quartz lens combined with higher dispersive but weak refractive crown glass, also gives very good results. It is easy to perceive that such a double combination is not only anastigmatic, but apochromatic also, because the difference of relative dispersion is very small, and the chromatic aberration to be corrected is a minimum, as in the case of quartz and crown glass.

2. Take two lenses with a minimum of spherical aberration for distant objects, as for instance the plano-convex lens, the spherical aberration to be corrected by the second plano-concave lens is so small in amount that the combination of two plano contacts, one convergent and the other divergent, with their flat sides turned to each other, shows so little over-correction at an aperture of *f*·15 to *f*·20 that the lateral deviation scarcely exceeds an arc second, as may be proved by a simple calculation (*Comptes Rendus*, Feb. 19, 1894). Further reduction of aperture reduces the same to a quite imperceptible amount in relation to the third function of the disphragm.

3. If the lenses are homofocal, that is, if the foci in both cases are the same, or nearly so, that the image produced by the plano-convex lens is bent to approximately the same extent as by the plano-concave lens placed behind it, the curvature of image at the focal plane of the symmetrical combination must, of course, be very small. The double combinations have absolutely no secondary spectrum, owing to very small difference of dispersion of the colourless media, and they give optically and actinically corrected images, which means that each pair of lenses may be used equally well for photography as for telescopic purposes, and there is a minimum loss of light. Such pairs of lenses, therefore, give images free from chemical difference of focus, as will a mirror.

The importance of these advantages for astro-photography and spectro-photography is apparent, and is increased by the perfectly flat field of about forty degrees.

But one may also combine two such lenses and obtain an aplanatic combination similar to Steinheil's, but of more extensive field for wide-angle pictures. I have repeatedly drawn attention to the importance of symmetrical lens systems for the construction of telescope and microscope objectives. I was also first to point out, in the year 1875, that the spherical aberration of reflectors could be corrected by a system of two homofocal lenses, that is, two lenses, positive and negative, of equal focus, made of the same glass. This without producing any chromatic aberration in the image, consequently without focal difference, and maybe with less distortion. In his anastigmats, Zeiss has recently made effective use of homofocal double lenses without focus. These, instead of a reflector, have a collecting lens corrected by two other lenses, which do not appreciably alter the focus, but they correct distortion and chromatic aberration, and, by reason of the kinds of glass, astigmatism also.

It is therefore possible to suitably correct all errors of the single lens, "chromatic and spherical aberration, distortion and astigmatism," with only two lenses (of two refractive media), by duly selecting the same, as in the human eye, according to form and substance, and it is even possible at the same time to attain a higher degree of apochromatism than with the best sorts of the new Jena glass. If, in addition, only light crown glass is used, the lens would be unaffected by atmospheric conditions.

Professor K. W. Zenger.

RONTGEN'S PHOTOGRAPHY OF THE INVISIBLE.*

Another peculiar effect of these rays has been investigated by Professor J. J. Thomson, and consists in the facility with which they discharge an insulated body charged with either positive or negative electricity. In fact, any substance, however good an insulator it may be under ordinary circumstances, seems to become a conductor of electricity during the time that the Röntgen rays are passing through it.

This can be shown experimentally by means of a gold-leaf electroscope such as I have here. This electroscope indicates the presence of an electric charge in the metallic disc on the upper part of the instrument by the divergence of the two gold leaves, which, when electrified similarly, repel one another. As you will observe when I charge the disc by means of a piece of rubbed glass or sealing-wax in the ordinary manner, the disc holds its charge fairly well. I will now allow the Röntgen rays from a Crookes' tube to fall upon the disc through an aluminium window cut in this lead screen. As you will see, the leaves immediately fall together, showing that the electric charge rapidly leaks away. As you will see, whether the disc be electrified negatively or positively, the result is the same. If, however, I close the window in the lead screen by means of a sheet of lead, you will now observe that the leakage is very much less rapid. The experiment, in fact, demonstrates the fact that lead is much more opaque to the Röntgen rays than is aluminium. Consequently this method can be applied even better than can photography to the exact determination of the opacity of various substances to these rays. It can also be used for the purpose of noting the intensity of rays that are generated by any particular Crookes' tube.

The best form of Crookes' tube to employ for practical photography of the invisible, or rather hidden, depends considerably upon the description of electric current that is available. When continuous or direct current obtained either from primary batteries, storage cells, or from the street mains can be used, and this current, which primarily is of comparatively low voltage, is transformed up to the necessary high voltage by means of an ordinary Ruhmkorff coil with its contact breaker, tubes of the form shown in the diagram on the wall will be found to give excellent results. In this description of tube the cathode consists of a plate of aluminium, and it will be found that the Röntgen rays proceed from the tube from a patch on the glass which is more vividly phosphorescent than the rest, which is immediately opposite the cathode plate. Where the anode is placed, it does not seem to greatly signify.

This is the form of tube, I believe, employed by Professor Röntgen himself; but during the last few days Messrs. Newton have placed on the market in London a new form of tube, which certainly gives very superior results. It was, I understand, designed at King's College. In it the cathode plate is made concave, so as to focus the cathode rays upon a point on a piece of platinum foil, which forms the anode. The platinum foil is bent at an angle of 45° to the direction of the cathode rays, so as to throw down the Röntgen rays, which in this tube proceed from the platinum, and not from the glass. This tube has two great advantages: firstly, as the Röntgen rays proceed practically from a point, it gives a sharpness of definition otherwise unattainable; further, since the cathode rays are directed on the platinum and not on to the glass, there is much less chance of the tube being destroyed by heating and cracking of the glass, and for this reason it is possible to excite the tube to a much higher extent, and consequently to work with shorter exposures than is practicable with any other tubes with which I am acquainted. In fact, from the point of view of the practical applications of Röntgen photography, it appears to me that this tube represents the most important advance yet made in connexion with the required apparatus.

When, however, direct currents are not available, and alternating currents must be used, an entirely different arrangement appears desirable. In this case, since each terminal of the tube is alternatively positive and negative, it is necessary that each must be capable of performing the functions of cathode. It is also necessary that the radiations should proceed from a single part of the glass, or otherwise the resulting photograph may be complicated by the production of double shadows. With alternating current, the form of tube shown in fig. 2, on the wall, in which one terminal is a circular plate and the other a concentric ring of aluminium, will be found suitable, and for the purpose of exciting such a tube the so-called high frequency arrangement of Tesla will be found very efficient. In this arrangement the alternating current, having been transformed up to, say, something like 20,000 volts, is employed to charge Leyden jars, which can discharge themselves across a spark gap, and are also connected to the primary of a second coil immersed in oil, to the secondary circuit of which the terminals of the tube are attached. The precise arrangement of the connexions is best seen by means of a diagram, which I will show in the lantern. So much for the form of the tube, but there are other points of the highest importance in connexion with its manufacture. First of all, it is necessary that the tube itself be constructed of what is known as German glass, that

* Continued from page 181.

is to say, glass in which soda is employed, and not lead, as is used in English glass. Further, the tube must be exhausted to an extremely high extent. What is exactly the best exhaustion is a matter of some uncertainty. The exhaustion can be too high, in which case it will not light up properly, but, in most of the tubes with which I have had myself to deal, it has been more often too low. In order to get really the best results with the shortest exposures, probably the best arrangement is to keep the tube connected all the time to a mercury pump, so that the amount of exhaustion can be increased or decreased to the exact extent that experiment shows to be advisable. This arrangement is perhaps the more necessary, for the reason that, though tubes may, when new, be exactly in the very best condition as regards exhaustion, it is unlikely that they will remain for long in this condition. In some cases the vacuum will become higher, and in some cases it will become lower with use. In the former case this is probably due either to absorption of the residual gas by the electrodes, or by condensation of the gas upon the glass, and, in the latter case, to some gas absorbed or occluded by the electrodes or condensed upon the glass being driven off by the heating that accompanies the passage of the electric discharge.

I will now show you a Tesla coil of the description mentioned, but of considerably large size than is necessary for merely exciting Crookes' tubes in operation. As will be observed, the nature of the electric discharge of such a coil differs very considerably from that produced by an ordinary Ruhmkorff coil, and, as you see, it will brilliantly light up Crookes' tubes connected to any one terminal, or even tubes with no terminals or connexions at all, that are merely held in its vicinity.

There can be no question that the Tesla-coil arrangement is very efficient for the purpose of producing the Röntgen rays from a Crookes' tube. It is, however, exceedingly destructive to the tubes themselves, and, though I am inclined to believe that with specially constructed tubes capable of resisting its action, a greater intensity of Röntgen rays are produced than with the ordinary Ruhmkorff coil, still, with such tubes as can at present be obtained, the latter is probably the more practical arrangement.

I now propose to actually take some photographs by the Röntgen method, and the results will be developed, and, if successful, will be shown to you in the lantern. We have here six photographic plates, of the commercial gelatino-bromide description. Each plate is enveloped in a double envelope of black paper, to protect it from ordinary light. We will place these photographic plates on the table, and upon them various objects, such as a purse containing coins, a pair of spectacles in their case, a pencil, &c. Above the objects, at a vertical distance of some eight or nine inches, we suspend the Crookes' tube. We will give an exposure of forty-five seconds.

We are using here, and I have always used, ordinary photographic plates coated with gelatino-bromide of silver. I do not think, however, that it at all necessarily follows that ordinary photographic plates which are made so as to be most sensitive to ordinary light, are the best for Röntgen photography. In any case it appears to me probable that the sensitiveness of photographic plates to these rays might very probably be largely increased by treating them with fluorescing substances, or even by arranging a fluorescent screen to be in contact with the film during the exposure.

At the beginning of this paper I mentioned how it was possible to render visible to the eye the invisible ultra violet-rays of the spectrum. It is interesting that, by a similar method, it is possible to render visible the Röntgen rays, and thereby actually to see the shadows cast by those rays of hidden objects, and even of the bones within the living body. Lenard was the first, I believe, to discover that it was possible to produce luminescence in phosphorescent substances outside a Crookes' tube. Röntgen investigated the subject further, and states in his paper that, by means of a fluorescent screen, formed of paper impregnated with platinocyanide of barium, it was possible to make visible to the eye the shadows cast by the bones in a human hand.

More recently, Prof. Salvioni, of Perugia, has described an instrument which takes advantage of this phenomenon, and which consists of a cardboard tube, at one end of which is an aperture to which the eye is applied, the other end being furnished with a screen made opaque to ordinary light, and coated on its inner side with phosphorescent material. I have such an instrument here, and by its means I have been able to see distinctly the shadows not only of coins in purses, of metallic objects in wooden boxes, and through aluminium plates, but even with considerable distinctness the bones in the thicker portion of my own hand. The method of using the instrument is very simple. The eye is applied at one end of the tube and fixed upon the fluorescent screen in the interior, while against the back of the latter is placed the purse, hand, or other object to be observed. On the other side of this object is the Crookes' tube, so that the rays cast the shadows of the objects upon the screen. This fluoresces more or less according as the rays are free to pass or are intercepted, with the result that a visible image is formed upon the screen. This instrument at present is very imperfect, but it seems capable of considerable improvement. For surgical and medical purposes it would indeed be an advantage if the bones and interior organs of the body could be inspected without the necessity of tedious photographic processes. Even in its present shape, however, the instrument is useful, for the reason, that by its means it is possible at once to determine whether a tube is working satisfactorily, whether it is giving a sufficient intensity of rays, and whether the shadows cast by it are sharp. It will also show that the glass, when fatigued, does not transmit the Röntgen rays.

Professor Röntgen's discovery is undoubtedly one of very considerable importance. It has excited the popular imagination in a manner unknown since the days of the telephone and microphone. Already, though it is but a few weeks old, the discovery is bearing fruit, in that it is being daily applied in practical surgery, more especially for the purpose of locating needles, bullets, and other extraneous objects which have become embedded in the flesh. On its further improvement it can scarcely fail to become still more valuable, as there seems every prospect by its means of being able to determine the extent of calcareous deposits in the interior organs of the body, malformations and diseases of the bone, &c. It may, in time, be possible to photograph, or even—and this would be still more useful—to actually see the interior organs in operation; and it is scarcely necessary to point out the extreme advantage that this would have, not only for the purpose of determining and curing the ills to which flesh is heir, but also in investigating and understanding many of the obscure processes which take place within the body.

Further, as we have seen, the discovery is of extreme interest from a point of view of physical science, giving as it does fresh insight to many matters of the highest scientific importance. It is not many years since Lord Kelvin stated that the discoveries of Hertz had annexed the whole science of optics to the domain of electricity, and the labours of Röntgen and Lenard have advanced us yet another step towards a knowledge of the real nature of both luminous and electrical activities. It is by slow degrees that the mists which obscure the panorama of the universe are dissipated, but the prospect surely widens year by year.

Discussion.

Mr. Brooks said, in March 1877 he made a communication in that room to the South London Photographic Society with regard to non-luminous actinic rays, but he had no electric appliances, and used a horse-shoe magnet. By exposing plates in complete darkness to the action of the magnetic field he obtained certain images, and found that even outside that there were invisible rays by which he could photograph through blackened cards, as had been shown that evening; but, when he brought this subject forward, it was pooh-poohed, and so he let it drop. He should now renew his experiments, especially as he had seen some things now which explained what he could not then understand. He found that the rays he used were not due to magnetism, although associated with it; and he also found he could even get rays from the fingers. In those days wet plates were universal, and a friend of his asked him for some chemicals and a bath to prepare some plates; he gave them to him, but next day his friend said they were useless, for every plate fogged. He himself then excited a plate, and exposed it, and found it perfectly clear, and so he came to the conclusion that there was some effect due to his friend's personality, and he proved this to be the case, for the placing of his friend's hand on the back of a plate was enough to fog it. In those days there were no pneumatic holders, and each plate had to be held by the corner, and, on investigating the matter, he found that in, about two or three per cent. of cases, rays were given off from the tips of the fingers which shoot out two or three inches.

The Chairman proposed a cordial vote of thanks to Mr. Swinton for the interesting and almost epoch-making paper he had read. He had done a real service to science in bringing before the general public the remarkable results that Professor Röntgen had obtained so shortly after their discovery. The more the public were interested in scientific matters of a genuine kind, the more secure would be the future of England. There might be material isolation, but there was no possibility in the future of intellectual isolation. Consequently, a scientific discovery of such great importance as this, which had awakened public interest in every country in the world, was something to be really thankful for. It was stimulating to the cultivation of real science to have a brilliant discovery like

his (probably the most remarkable which had been made within the last half-century, seeing that it had been rendered practically useful within less than three months of its publication), generally appreciated. They could see no end to the future work in abstract science which it opened up. It had, at the same time, stimulated a kind of criticism to which, perhaps, Mr. Swinton would be exposed, but which, in his opinion, ought not to be entertained. That was the view that a scientific discoverer had some kind of monopoly for an indefinite period of time in his discovery, and that his position was similar to that of an inventor. He should not have been surprised if this view, which had recently been promulgated in the scientific journals, had led to a kind of injunction being asked against their friend. He could not understand that position. There was no monopoly in science, and he felt convinced, though he had not the honour of knowing Professor Röntgen himself, that he would not regard this widespread interest in his work as in any way detracting from his merits, but rather as adding new laurels to the value of the original investigation. He was sure Mr. Swinton would be the last man to do anything else than exhibit the marvellous fertility of Röntgen's discovery. To say that any investigator, if he locked the door of his laboratory and cultivated his own garden—as had been suggested—for a permissible period, could have done as much in three months as had been done in this case through publicity, would be simple nonsense. He could not but think that such ideas rather suggested that, instead of having regard to the real objects of science, there was too much consideration being given to the personality of the investigator. Now, the merits of the investigator had often very little to do with the importance of the discovery. That was one reason why there could be no such thing as monopoly. Look at the antecedent work involved in Professor Röntgen's discovery. On the one side you had the heredity from Faraday, who first suggested lines of force, to the great development made by Maxwell, to the work of Varley, and to that of Crookes. On the other hand, you had the work of Herz, Lenard, and the work of Professor Röntgen. There were three Germans who had cultivated this field, and at least four Englishmen who had done admirable work. We, therefore, had our own share in the development of Röntgen's discovery, and every step had been necessary to the ultimate achievement. Of course, they always felt that somebody else might have discovered something, and that it was a pity he missed it; but really one man could not expect to monopolise everything, and there was plenty yet to be found out. You had only to go over the most elaborate investigation of the most brilliant man before you, and you would be sure to find something he had not seen, something the world ought to know. As regards the theory of the X rays, he noticed that Mr. Swinton was much in the position of other investigators—he declined to commit himself. He had put several suggestions before them, and they must select the one which seemed to them most suitable. Probably Professor Röntgen was well advised in calling them the X rays. The problem still awaited solution, but probably within a year they would know more about it. If not, it certainly would not be for want of minds all over the world best able to deal with these abstruse problems being concentrated upon it. They could not but feel that they were on the dawn of new knowledge with regard to the most recondite and most interesting of all kinds of substance, viz., the material medium called ether. That was really, they believed, what they were now touching, and that, after all, was the most widespread medium or material in the universe, connecting world to world, the stellar system and the nebulæ to our earth, and yet, at the same time, the means of communication between atom and atom. This discovery seemed to open out a new mode of attacking the ether, and to show a new and striking use to which this medium can be put. First light, then electricity, and now a new kind of radiation, which it would take years of labour to investigate, had been in succession added to the functions of the ether. But, at any rate, the brilliancy of this discovery would remain, and their thanks were due to Mr. Swinton for the admirable way in which he had brought it before them.

A. A. C. Swinton, A.M.I.C.E., M.I.E.E.

ON A NEW METHOD OF PREPARING PLATES SENSITIVE TO THE ULTRA-VIOLET RAYS.*

[Communicated by Colonel J. Waterhouse, I.S.C.]

I.—Preliminary Preparation of the Plate for Coating with Silver Bromide.

If plates prepared as above† are treated with hypo, the greater part of the developed picture flows away as soon as the remainder of the yellow ground of the plate forming the unexposed parts disappears. This defect may be prevented by:—

(*a*) Preparing the silver bromide film very thin.

(*b*) Coating the glass plate with some binding material before depositing the silver bromide.

(*c*) Mixing the bromide itself with a binding material.

(a) With a thick film the developed picture rests upon a layer of unaltered silver bromide, and by the fixing this is replaced by an equally thick layer of fluid, which causes the picture to be suspended close over the glass. If the tray is moved, the film forming the picture is broken up, and floats off. With a thin coating the greater part of the image is reduced all through the film. The fixing solution then acts more on the sides of the reduced silver than underneath it, so that the undermined parts of the film remain fast to the glass along with the other parts, and are prevented from being washed away. But the use of silver bromide without a binding material is not to be recommended. Even with a proper thickness of film, the plates require the greatest care after fixing.

In cases when the employment of a binding material is not permissible (as when it is desired to ascertain the behaviour of the spectrum with pure silver haloid), it is better not to fix at all. In darkness the plates can be preserved unchanged in colour for a long time. If the plate must under any circumstances be fixed, then it is better to employ a gelatine bath first. This also gives the finished plate more resistance. The fixed image from a thin film of pure silver haloid on plain glass has no strength, and is very sensitive to mechanical pressure.

(b) If the glass plate to be sensitised is first coated with gelatine, then even a thick film of pure silver bromide holds so strongly, that the fixing with hypo does it no injury.

For this substratum I use a warm two per cent. solution of gelatine, which is liberally poured on to the carefully cleaned and warmed plate, and allowed to flow over it and run off at one corner. The plate is then stood up to dry, in a place free from dust, on blotting-paper, with the prepared side inwards, and coated soon afterwards with the silver bromide.

The coating of silver bromide is very sensitive to irregularities in the gelatine coating—particles of dust, burst air bubbles and inequalities in the coating, spoil the deposition of the silver bromide and give rise to a number of defects in the plates, which in most cases do not appear till the development. The coating with gelatine must therefore be done with the greatest care. Above all, air bubbles must be avoided. Even the smallest bubbles burst, and, where they are, the surface of the glass is exposed, and this, in certain cases which will be referred to later, in consequence of the insensitiveness of the silver bromide deposited upon it, becomes uncovered on the developed plate all round them.

The gelatine coating should be as thin as possible. The thinner it is, so much the less will the almost unavoidable differences in its thickness affect the silver bromide film; the stronger the image sticks to the glass, the less stained becomes the gelatine in the developer. Another advantage to be noted, especially with very small plates, is that, as the plates must be cut from the prepared side, the cutting can be done much more neatly and exactly through the film in proportion as the gelatine is thinner. (The plates cannot be cut from the back on account of the tenderness of the film of bromide.)

(c) If the bromide of silver is itself mixed with a binding material, then the substratum of gelatine is unnecessary. This can be done in a suitable way by precipitating the silver bromide from solutions containing gelatine. In this case the particles of bromide, as is well known, contain gelatine, and, as I first of all observed, hold extremely firmly when applied on glass and dried.

The proportion of gelatine in my silver bromide solution varied between 1 : 18,000 and 1 : 1550. Its influence on the sensitiveness of the plates will be considered later.

It should, however, be mentioned at once, that for reasons, which will be explained hereafter, I now use the gelatine substratum for all plates, even when the silver bromide contains gelatine.

II.—Preparation of the Silver Bromide.

(*a*) *Without Gelatine.*—To prepare silver bromide as a fine precipitate, settling itself gradually, requires very strongly diluted solutions and a large excess of potassium bromide. I dissolve 2·8 grammes of potassium bromide in 4 litres of distilled water, and 2·0 grammes of silver nitrate in 100 c.c. of distilled water, and in the light of the dark room pour the silver solution in small quantities into the bromide solution, constantly stirring the while. The liquid so obtained is tolerably translucid and coloured red by transmitted light, and after filtering is ready for the precipitation of the silver bromide. In this case I do not use the whole of the silver bromide, but content myself with what falls in one or two

* Translated from the *Sitzungsbericht der Kaiserlichen Akademie der Wissenschaften, Math-Naturwiss. Classe*, Band cii. Heft. 8, Wien, October, 1893, pp 994-1024.

† The British Journal of Photography, January 31, 1896.

days. To wait till the fluid over the plate is quite clear would take weeks.

The liquid with the precipitate becomes visibly denser as soon as ammonia is added. The bromide also settles much quicker than before, and ten to twelve hours will be sufficient. For this purpose I add 30 c. c. of ammonia to the above solution.

(*b*) *With Gelatine.*—To the solution of potassium bromide given above I add 0·2 gramme of hard emulsion gelatine, dissolved by heat, and otherwise proceed as before. Ammonia also acts beneficially on the formation and settlement of the silver bromide precipitate.

All these methods yield a silver bromide which is only slightly sensitive even when prepared with warm solutions. Greater sensitiveness was obtained by prolonged heating of the suspended silver bromide. The strongly diluted solutions are not well adapted for this, and better results can be obtained with an emulsion weak in gelatine. If this is dissolved in proper quantity in hot water, the silver bromide precipitates gradually. It also contains gelatine, but gives a more sensitive coating than bromide, which is deposited from very dilute solutions.

The emulsion I use for this is composed as follows :—

A.

Potassium bromide	12 grammes.
Emulsion gelatine	2 ,,
Distilled water	200 c. c.

B.

Silver nitrate	15 grammes.
Distilled water	200 c. c.

A is dissolved with heat, and B, also warmed, is poured in very gradually in small quantities in the light of the dark room. During the mixing, A must be kept well stirred.

The unripened emulsion can be used at once for precipitating, but the plates are then scarcely more sensitive than in the former method. Greater sensitiveness must be obtained by warming or boiling the emulsion, adding ammonia or other means usually employed with sensitive gelatine emulsions as laid down in the text-books. The only precaution to be taken during the ripening is to keep the emulsion well shaken, as, owing to the small quantity of gelatine, a good deal of the bromide will settle to the bottom. 100 c. c. of this emulsion, dissolved in 4 litres of water, shaken up and filtered several times, give a good precipitating fluid. It is well to allow the solution to stand a few hours before use, in order to allow the heavier particles of dust and other impurities which may go through the filter to settle, so that at least the heaviest of them may be kept off the plate. By this precaution the formation of a number of small defects on the plate, even if they may be almost microscopic, is avoided.

The silver bromide can also be obtained from ordinary gelatine dry plates, though the emulsions are of different degrees of richness in gelatine. The emulsion is dissolved in a suitable quantity of hot water, and the further procedure is as before. These plates also have great sensitiveness for the ultra-violet rays. My observations with them have, however, not extended beyond w. l. 170$\mu\mu$. I have no doubt, however, that these plates would be useful beyond that point,

The employment of ordinary dry plates can only be considered when it is desired to prepare plates sensitive to the ultra-violet with the least expenditure of time, trouble, and costs. When it is a matter of only a few experiments, or perhaps it is merely desired to ascertain the behaviour of the new plates, it is better to take the silver bromide from the coating of commercial plates. For this purpose a plate of this kind is cut into slips 1 or 2 cm. wide, which are placed in a flask full of hot water (0·5 to 0·6 litre to a plate 13×18 cm.), and well shaken. As soon as the coating of emulsion has dissolved, the contents of the flask are filtered, allowed to stand quietly for about an hour, and then poured into the precipitating dish, in which a second dry plate has been laid with the coated side upwards.

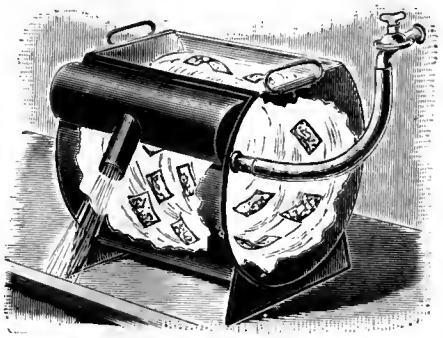
Our Editorial Table.

TYLAR'S P. O. P. WASHER.

W. Tylar, 41, High-street, Aston.

THE features of this handy little washer are—(1) The inlet is so placed that a circular motion is given to the prints, and (2) The position of the outlet prevents overflow. Once the water is turned on,



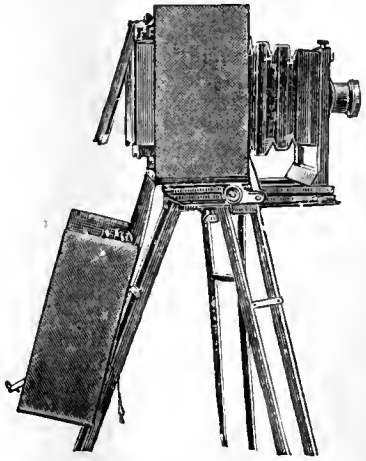
the washing proceeds neatly and automatically. The P. O. P. Washer is a thoroughly useful and efficacious addition to the amateur's outfit. When using it, Mr. Tylar recommends that the prints be put in one after the other. "They can then be left, providing no boys are about."

THE ALBION COMPANY'S NOVELTIES IN PHOTOGRAPHIC APPARATUS.

The Albion Alumenising Company, 96, Bath-street, Glasgow.

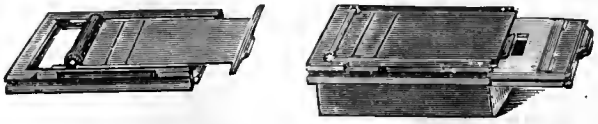
THIS well-known northern house is issuing several novelties in photographic apparatus, which are likely to appeal, not without success, to the sympathies of amateur photographers.

THE AYE-READY CAMERA.—This camera, which embodies every necessary movement, has the further advantage of being complete in its own case. It will be seen from the illustration that, attached to



the base board of the camera, is a portion of the case in which the camera itself may be packed, and that contains the dark slides. Space is given for other items of apparatus, such as the lens, &c. The camera, when not required for use, packs up into a neat case, and is therefore virtually self-contained.

THE "REPEATER" CHANGING BOX.—The features of this changing box are that an unlimited number of plates can be changed in full daylight. Plates or films may be exposed at will. There is no



heavy box on the camera, as the plates or films are manipulated in a slide one at a time. The envelopes used for carrying the plates before and during exposure can also be used for storing them.

In use, the plates are placed in the light-tight envelopes in the dark room, and sealed. They can then be handled in daylight without fear of fogging. Each plate is placed in the slide singly, and the tag attached to the roller fitting, which, when the shutter is drawn, pulls off the front of the envelope and exposes the plate. After exposure the slide is removed from the camera, and the plate dropped into a special box. To accomplish this, the slide is attached to the box, and the shutters of the slide and box are drawn together. Inside the changing box is a cardboard box, which holds twelve plates; when filled, this can be removed in full daylight and another substituted, and so on indefinitely.

The Inquirer.

*** *In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* JOURNAL *useful and instructive.*

COLOUR SCREENS FOR ORTHOCHROMATIC WORK (To C. P. R.).—Pure chromate of potash was specified, not the red dichromate or acid salt. C. P. R. correctly describes it as of a lemon yellow colour, having great tinctorial power; this pale colour in conjunction with its power of intercepting the blue and violet rays makes it so eminently suitable for the purpose, giving better results with shorter exposures than any other colouring matter I have tried. Some workers recommend that the aqueous solution should be rendered slightly alkaline with carbonate of potash; but I have not found this necessary. In making the solution distilled water should always be used. C. P. R. should make his experiments in glass tubes, so as to judge his solutions by transmitted light, not by reflected light in the way described; he is, however, substantially correct in his deductions of the tinctorial powers of the two salts in dilute solution.

F. H. BURTON.

News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday next, April 8, Members' Open Night.

THE General Meeting of the King's Lynn Y.M.C.A. Photographic Club was held in the Society's rooms on Monday, March 16, Mr. C. W. Perry in the chair. The following are the appointments for the coming year:—*Chairman of Committee:* Mr. J. O. Reynolds.—*Committee:* Messrs. Bridges, Johnson, and Smyth, and Mesdames Andrews, Reynolds, and Ramsell.—*Treasurer:* Mr. E. H. Andrews.—*Secretaries:* Messrs. F. Hampton and W. M. Lock.

Patent News.

THE following applications for Patents were made between March 18 and March 25, 1896:—

BURNISHING MACHINE.—No. 5789. "An Improved Rotary Burnishiug Machine for Photographic Purposes." T. S. HARGREAVES.

CAMERAS.—No. 5928. "Improvements in Photographic Cameras." Complete Specification. Communicated by the Automatic Camera Club, United States. H. H. LAKE.

EMULSIONS.—No. 5992. "Improvements in Photographic Emulsions." H. WANDROWSKY.

STANDS.—No. 6075. "Improvements in Stands for Photographic and other Apparatns." Complete Specification. Communicated by C. Chorretier. B. J. B. MILLS.

MOUNTS.—No. 6145. "Improvements in Photographic Mountings." J. F. HOYNE and D. B. ATHOL.

LENS DIAPHRAGMS.—No. 6421. "Diaphragm System for Lenses used in the Half-tone Photo-engraving Process." A. W. PENROSE and W. GAMBLE.

VIEWING PHOTOGRAPHS.—No. 6245. "A Method of and Apparatus for Taking and Viewing Photographic Pictures." M. FREUDENBERG.

RECORDING EXPOSURES.—No. 6277. "Improvements in Recording the Exposure of Photographic Plates and other Subjects." E. MOSELY.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
6.....	Hackney	Excursion: West Drayton. Leader, A. Dean.
7.....	Darwen	*Tour in Switzerland.* G. Butterworth.

10.....	Moseley and District	*Miscellaneous.* Walter Griffith.
10.....	West London.....	*Some Industrial Applications of Photography.* Donald McBeth.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 26,—Mr. E. H. Bayston in the chair.

Mr. W. H. Smith was elected a member.

The following question was read: "From whom can a permit to photograph at the Zoo be obtained?" Application to the Secretary of the Society was recommended by Mr. Freshwater, although he thought a permit was not necessary.

THE BACKING OF PLATES.

Mr. R. P. DRAGE, in connexion with the statement that as good work can be done on unbacked plates as on backed plates, said he had recently seen a collection of slides of Lincoln Cathedral by Mr. Evans, who had told him that he never used any backing, and in only one of the whole series was there any trace of halation.

The HON. SECRETARY said one could get a very good slide indeed from a weak negative, and, if the ultimate object was only to obtain a slide, the halation might be avoided by purposely making a weak negative.

Mr. T. E. FRESHWATER had seen platinotype prints of the photographs in question, and said they were not from thin negatives, which, he thought, moreover, did not lend themselves to this printing process.

Mr. A. HADDON could not see how, by tentative development, one could avoid bringing up halation, and did not think development could be made selective.

The HON. SECRETARY inquired the necessary outlay for the plant involved in slide-making by the Woodbnry process.

Mr. ATKINS said it was somewhat expensive on account of the press, and estimated it at about 50*l.*

The HON. SECRETARY again brought the Traill Taylor Memorial Fund before the members, and passed round a subscription list.

Slides by Messrs. Freshwater, Kellow, Drage, and others, were shown on the screen, including some by the Woodbury process.

PHOTOGRAPHIC CLUB.

MARCH 25,—Mr. John Nesbit occupied the chair.

Mr. FRED H. EVANS gave an excellent lecture on

LINCOLN CATHEDRAL,

illustrated by about 100 lantern slides. The lecture was most interesting, and the pictures among the best architectural photographs we have ever seen. Mr. Evans informed his hearers that some were taken on plates and some on films, but in neither case were they backed, the excellence of the pictures being mainly due to full exposure and a suitable time being chosen for taking them.

After a very hearty vote of thanks to Mr. Evans, a series of slides were exhibited, kindly lent by Messrs. R. W. Thomas & Co., from negatives taken on their anti-halation plates.

Camera Club.—It is abundantly evident that a great satisfaction is attached to the examination of one's osseous structure, otherwise it would be difficult to account for the circumstance that two large congregations of sane beings have recently assembled at the Camera Club in order that their hands, feet, elbows, wrists, ankles, &c., might be portrayed *à la* Röntgen. The operator in each case has been Mr. H. Powles, a member of the Club, and one of the leading spirits at the Electrical Standardising, Testing, and Training Institute at Faraday House, close by. On the first occasion Mr. Powles had no fewer than twenty-five patients, or, perhaps we should say, models, who were anxious to see the bony structure of their extremities, or to trace the effects of old wounds, or the presence of foreign bodies. Before the discovery of Röntgeu's method of exhibiting the bones, people kept their slight injuries and the maimed condition of their limbs to themselves as strictly private matters, but now they are only too proud to exhibit their defects. A broken ankle, which will show well with a Crookes' tube, is regarded as quite an enviable possession, and if one can only show a bullet or even a few leaden pellets which have entered his leg instead of the more fortunate bunny at which they were aimed, he at once advances a long way in the estimation of his fellows, so that Mr. Powles had no need of interesting subjects for dissection by the far-seeing Röntgen rays. Indeed, the members of his Club, like Oliver Twist, asked for more, and therefore a second *séance* was arranged, which came off with great *éclat* on Wednesday last week. Mr. Powles did not attempt to give a lecture it was rather a demonstration, or series of demon-

strations, in which the company present took an active part. One had a wounded hand, another a dilapidated foot, while a third had a knee full of shot, each stepping forward in turn to be operated upon by the Surgeon-in-chief, Mr. Powles, who sat at a table, upon which were two powerful induction coils, which buzzed away like swarming bees. The only notable difference in the apparatus employed on this occasion and that used by Mr. Campbell Swinton in the same room some weeks ago, was in the pattern of the Crookes' tube. Mr. Swinton had the disadvantage of being the pioneer worker of the Röntgen process in this country, and had to make use of such appliances as were ready to his hand. Mr. Powles, coming later into the field, has been able to reap the experience of others, and employs a radiant-matter focus tube of the pattern adopted by Mr. Herbert Jackson, of King's College, which has been generally accepted as a very great improvement upon older patterns. With a tube of this kind, Professor Owen Lodge, at Liverpool, has viewed, with the help of a fluorescent screen, the internal structure of a boy, and has seen through a mass of timber twelve inches in thickness. We are under the impression that the fine life-sized photograph of an infant, published last Friday as a supplement to the *British Medical Journal*, was also due to this modification of the Crookes' tube. It seems certain that, to obtain the best effects, the time of exposure should not be curtailed too closely. Mr. Powles gave an average for hands and feet of about six minutes, and with such an exposure development came up rapidly. For some occult reason, hydroquinone seems to give better results than pyro for this particular work.

Hackney Photographic Society.—March 24, Mr. R. Beckett presiding.—Mr. Dean announced the arrangements for the Easter Monday club outing to West Drayton, train to leave Bishop's-road or Paddington at 9.34 a.m. A paper on Enlarging by Mr. John A. Hodges was, owing to his unavoidable absence, read by Mr. W. Rawlings. All the details of the subject were clearly and exhaustively treated, and the paper was much appreciated by those present.

North Middlesex Photographic Society.—March 23.—Mr. A. J. Johnson gave a lecture on

Photography and Book Illustration.

Close upon a hundred lantern slides were thrown on the screen of wood engravings, half-tone work, and other methods in use for illustrating books and periodicals. As the slides were shown, he described the picture and method by which the result was obtained. Some very early examples of wood engraving and facsimile work were shown, also some specimens of American work, and the more modern "process." He explained the part photography took in these methods, and showed the nature of the grain produced by the screen by exhibiting part of a picture on a much enlarged scale.

Richmond Camera Club.—March 23, Mr. Alabaster in the chair.—Mr. Ardaseer gave a

Chat on Photographic Chemicals,

which was of great practical interest. After mentioning the foreign matter pervading our Richmond water, and rendering it without treatment unsuitable for photographic purposes, Mr. Ardaseer treated in detail of all the chemicals in ordinary use by photographers. He described first the developers, of which he mentioned seven. Secondly, preservatives: sulphite of soda (which commonly required the addition of sulphurous acid to produce neutrality), metabisulphite of potassium (better than sulphite, as being an acid salt), nitric acid (not good, being a powerful oxidiser), sulphuric acid (the best of the mineral acids), citric acid (not advisable owing to liability to form citrate of soda, a powerful restrainer). Thirdly, alkalies: liquid ammonia (of which one never could be sure of the strength), carbonate of soda (in using which an extra amount of sulphite should be used in the developer), carbonate of potassium, caustic soda, carbonate of ammonia, and bromide of ammonia, potass, and soda (the last being rarely used, though cheaper and apparently equally efficacious). Fourthly, ferrous oxalate developer for bromide paper, recommending that, for the preservation of ferrous sulphate in solution, it should be made strongly acid with sulphuric acid, and some scraps of thin iron wire placed in the bottle. Fifthly, fixing baths: hypo and cyanide of potassium. Sixthly, toning agents: gold chloride (which ought not to cost less than 1*s.* 8*d.* per fifteen grains, the cheaper stuff being part chloride of gold and part chloride of sodium or common salt), chloro-platinite of potassium, ammon-sulphocyanide, acetate and phosphate of soda, and borax. Seventhly, miscellaneous chemicals: alcohol, ether, nitrate of silver (the mode of saving which from old hypo baths was explained), alum (common and chrome), and pyroxyline. Mr. Ardaseer clearly explained the nature and properties of the various substances, dropped hints in lavish profusion as he went along, and concluded his "chat" by answering a number of questions.

Tooting Camera Club.—March 25.—Mr. Edwards demonstrated the use of

Cresco-fylma,

and imparted some very useful information to the members. The comparative ease with which he cut a blurred head from the negative of a group, replacing it by a better one extracted from another negative of the same group, was a revelation to most of those present. The experiments made in respect to enlarging of films and their transference to larger glass plates were very successfully carried out and watched with the greatest interest, and led to the suggestion that it would be a grand thing to soak the Club itself in cresco-fylma.

Liverpool Amateur Photographic Association.—March 26, the President (Mr. J. Sirett Brown) in the chair.—Messrs. A. H. Baird, Charles H. Hughes, G. R. Clarke, and G. P. Mulock, were elected members. Dr. J. W. Ellis read a few notes on the methods proposed to be adopted in carrying out a photographic survey of South-west Lancashire, after which Mr. Charles L. Burdick (of London) demonstrated the working of the Aerograph (or Fountain Air-brush), finishing with a very clever sketch of the President.

Oxford Camera Club.—March 23.—A demonstration of the

Photo-autocopyist

was given by Mr. Taylor, Manager of the Autocopyist Company of London. There was a large attendance. The process gives a ready means of obtaining a number of prints in any colour and of absolute permanence, their appearance resembling collotype. A gelatine film on suitable support is sensitised in a solution of bichromate of potash and dried in the dark, when it is ready to be exposed under the negative. The progress of printing can be seen as with ordinary print-out processes, so removing any element of uncertainty. When sufficiently printed, the sheet is washed from bichromate, stretched in a special frame, and inked with an ordinary printing-ink roller. The ink only adheres where the light has acted, and the sheet is then covered with the material to be printed on, and pressed in an ordinary copying press for a moment, when the print is finished. Several hundred prints can be made from the one gelatine sheet. The process was fully demonstrated by Mr. Taylor, and the results caused surprise at their refinement and the ease with which they were produced. Several sets of apparatus were ordered by members, and the process will be largely used in Oxford.

Correspondence.

ORTHOCHROMATIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—There are two small errors in your report of my demonstration at the Royal Photographic Society, on Tuesday. I did not tell Mr. Bolas that an exposure of from two to four times that required with "an" orthochromatic plate would, with an ordinary plate and a suitable screen, yield a fairly satisfactory result. I may have said, "with *one* orthochromatic plate," but the figures are correctly given in another part of your report. I also stated that Mr. Senior's photographs of the painting were made on *ordinary* plates, one of them with the bichromate tank, as originally recommended by me for use with chlorophyl plates. "Chromium green" light was not recommended for the development of orthochromatic plates generally, but only for the Cadett "Spectrum" and the Lumière series B.—I am, yours, &c., F. E. Ives.

24, *Southwick-street, Hyde Park, W., March* 27, 1896.

PHOTO-CHROMOSCOPES.

To the Editors.

Gentlemen,—Having now obtained a copy of M. Nachet's patent and "certificate of addition," I find that the facts are exactly as I suggested on p. 142. There is not the remotest suggestion of my apparatus in his patent of 1894; but, in his "certificate of addition," filed nearly six months after my application for a French patent and the publication of my United States patent (nearly a year after my legal date of record for both countries), he has inserted an exact drawing of my instrument, and claims for the same.

A careful examination of references that have already been given will suffice to completely refute the latest batch of "arguments" directed against my claims to original methods. I shall, therefore, no further encroach upon your space, except to ask for a reproduction of drawings of the various photo-chromoscopes discussed, with brief descriptions and patent dates, which are all to the point, and state the case as to invention of apparatus better than a mountain of words.

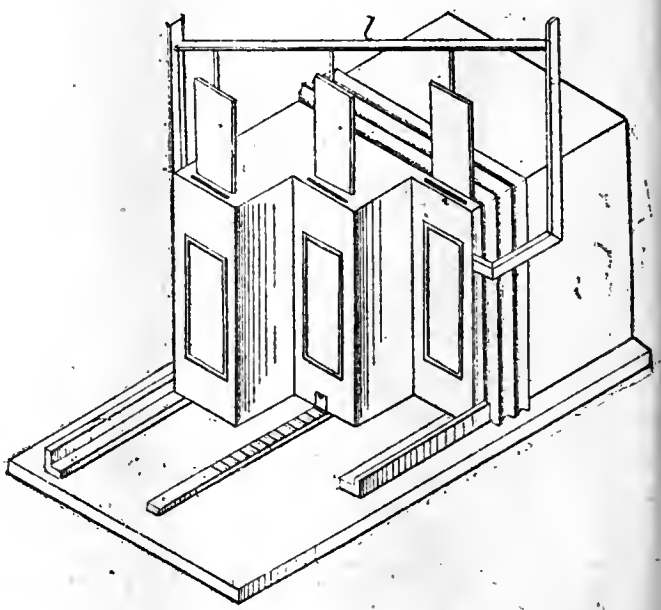

Photo-chromoscope of A. H. Cros, British patent No. 9012, May 30, 1889. Contained a revolving disc with mirrors and open sections, arranged to blend

the images by persistence of vision. Disc revolved by pulling a cord wound on the axle. A practical failure. Abandoned.

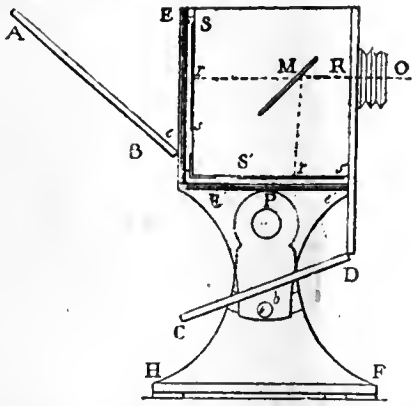

Photo-chromoscope of C. Nachet, French patent No. 237,394, March 29, 1894. Two images blended for one eye by viewing one image directly through a transparent platinised mirror, and the other by reflection from the same; the third image seen directly by the other eye. Neither a true photo-chromoscope nor a true stereoscope, but a hybrid device.

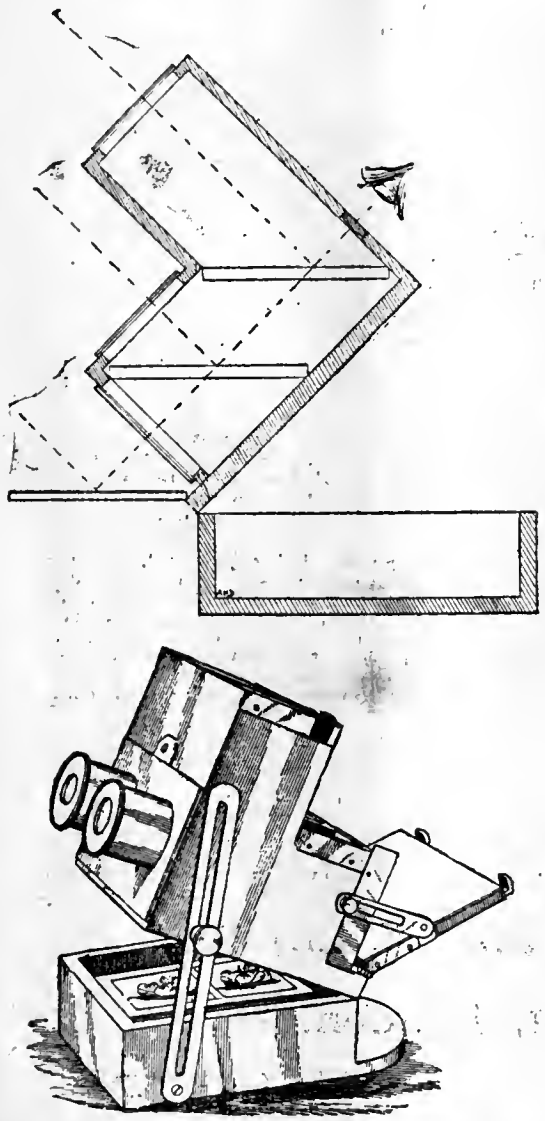

Photo-chromoscope of F. E. Ives, British patent, legal date July 3, 1894; issued as No. 2305, 1895. Same legal date in United States and France. Original features, patented, as follows: 1. Step form with steps horizontally disposed, and mirrors inclined in a horizontal plane. 2. Contraction to two-step arrangement, making the instrument simpler and more compact, and greatly increasing the angle of view and the apparent area of the image. 3. Hinged attachment to baseboard or tray, for regulating angle of inclination. 4. Stereoscopic arrangement. 5. Stereoscopic colour record consisting of three pairs of images. 6, Folding chromogram, by which all three sections are as readily placed and registered as a single section in Cros's unsuccessful instrument. Completely successful.

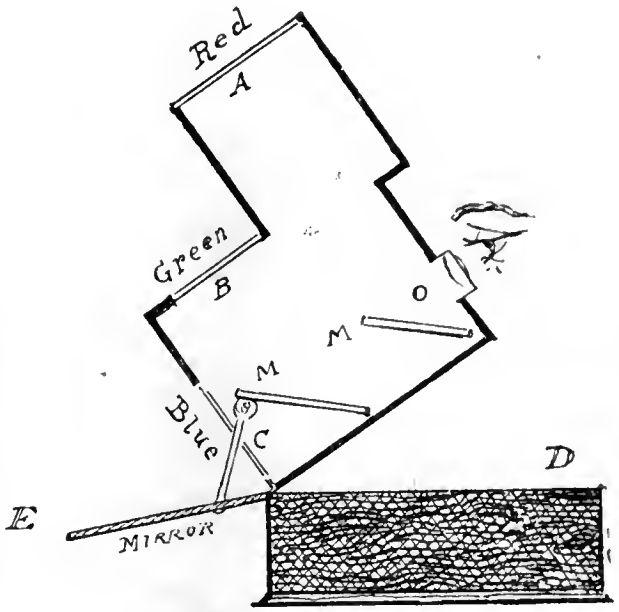
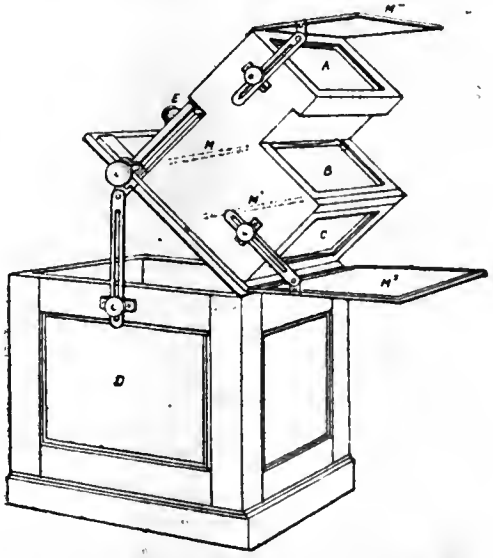


Leon Vidal's drawing of instrument claimed by C. Nachet, by patent "certificate of addition," dated June 7, 1895. Should be compared with Ives's instrument and claims dating July 3, 1894.



Claimed by B. J. Edwards, British patent No. 3613, February 19, 1895, but horizontal disposition of steps not shown until December 19, 1895. Should also be compared with Ives's instrument and claims dating July 3, 1894.—

I am, yours, &c., F. E. IVES.

24, *Southwick-street, Hyde Park, London, W., March* 28, 1896.

[This correspondence here terminates.—EDS.]

ORTHOCHROMATIC PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—Is it possible, after all that has been said, written, and demonstrated, notably by Mr. Ives, and supported by many other practical workers, there still remains a doubt that orthochromatic results can be obtained with ordinary or non-colour sensitised plates, and that it is in any way necessary to debate the matter theoretically to prove a fact which every worker of average intelligence can determine for himself? Theory is all very well in its way, but, when it does not conform to

practice, it must stand on one side until it gets into a more intelligent frame of mind. Academical discussions on a matter of this kind are not conclusive, so much depends on the special ability of some men to state a case, while others holding perhaps sounder views are unable to express themselves with clearness and decision.

Will those who doubt set up a coloured chart of the spectrum in their studios, and make a few negatives of it in good white daylight, using as screen a cell containing a one per cent. solution of chromate of potash and giving an exposure of ten times the normal without screen? If they don't succeed at the first attempt, they will at least secure a much improved colour rendering which will encourage them to further experiments and ultimate success; it is really so simple there is no need to sigh for an English Dr. Eder to conduct the operation.

To any one who has studied orthochromatic photography three points are abundantly clear:—

1st, that orthochromatic plates in a white light without screen have no advantage over the ordinary plate.

2nd, that orthochromatic plates with screen or yellow light give excellent colour values with moderate increase of exposure as compared with using them in white light without screen.

3rd, that ordinary plates with suitable screen will give as good colour values as orthochromatic plates, but require considerable increase of exposure.

This increase of exposure will probably prevent the extended use of ordinary plates for orthochromatic work; no ordinary plate will even give a better result than one specially sensitised for the purpose, and it is absurd to think that where in the ordinary plate all the results are due to the action of the screen, at a loss of speed, it will give better results than the orthochromatic plate which meets the screen more than half way and greatly reduces the exposure.

Ordinary plates will yield orthochromatic results under suitable conditions, but they will not supersede those specially sensitised for the purpose; loss of time so often means loss of subject.—I am, yours, &c.,

Roundhay, near Leeds, March 23, 1896. F. H. BURTON.

FOREIGN EXHIBITIONS.

To the EDITORS.

GENTLEMEN,—Kindly permit me to announce that I have been appointed British representative for the Lille (France) Exhibition. The exact dates have been altered as follows: Entries close May 20, pictures must reach me by June 8, and the Exhibition opens on June 27. Artistic merit alone will be recognised, no charge for space, no awards, but each accepted exhibitor receives a commemorative plaque.

For the Harlem (Holland) Exhibition I can receive entry forms up to the end of this week, April 4.

For both the above Exhibitions all details, forms, &c., may be obtained from me, and entries and pictures must be sent to my office. The latter will be forwarded in a joint case or cases and the carriage divided equitably.

Exhibitors at Brussels can have their work sent on direct to Harlem if they so advise me.

The delay with the Amsterdam medals is, I believe, due to unfortunate circumstances connected with one of the officials of that Exhibition, who has left Amsterdam altogether. Nevertheless, I think they will all be received shortly. The last advice, dated 24th inst., says that they have been sent out, and the writer adds, "I expected to cross to England some time ago, and intended taking the medals with me in order to reduce the expenses, but I have been detained."—I am, yours, &c.,

WALTER D. WELFORD.

15, *Farringdon-avenue, London, E.C.*

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

Harry S. Parsons, 15, Upper Gray-street, Edinburgh.—*Photograph of dogs and cat, named Chums.*

R. C. Whitehouse, 59, Piccadilly, Manchester.—*Photograph of John Henry Tyers with swimming trophies.*

R. G. Ashton, 27, Booth-street East, C.-on-M., Manchester.—*Photograph of Mrs. Jane Franklin, Mr. Duke Franklin, and a servant in front of the shop.*

RESIDUES.—C. G. & CO. The metals can be precipitated by sulphide of potassium—liver of sulphur.

COLLODIO-CHLORIDE.—WET PLATE. We are sorry we cannot assist you further. It is a matter that you will have to work out by experimenting yourself. That you should be able to do with the information already supplied.

COLLODION.—S. WALTON. Methylated ether will do quite well for collodion for the wet process, but commercial methylated alcohol will not. The latter will do for collodion for enamelling and suchlike purposes if it is of not less than sp. gr. ·820 or ·825, and free from the mineral naphtha.

RELATIVE RAPIDITY.—C. B. asks: "Will you kindly inform me what is the difference in the quickness of a Dallmeyer's 3D and a Dallmeyer's half-plate portrait? By so doing you will greatly oblige."—Supposing the portrait lens is of the A series, it will have nearly double the rapidity of those of the D series.

HYPOSULPHITE OF SODA IN PRINTS.—F. M. Make a *very* dilute solution of permanganate of potash in water so as to just give a pale tint. Then suspend a print, as it is taken from the washing water, till a final drop has collected at the corner. Let this drop into a little of the permanganate solution in a small test tube, and, if its tint is discharged, the print contains hypo.

STUDIO.—W. & CO. By all means adopt design No. 3 for general portraiture, in preference to any of the others. That form of studio is by far the easiest to work, and will fulfil every requirement. The No. 2 should be specially avoided, more particularly with the only aspect available to you, as it would be next to impossible to obtain satisfactory chiaroscuro in it when the sun is shining.

CHONDRIN.—EXPERIMENTALIST writes: "Where can I obtain some pure chondrin?"—We cannot say, as it is not an article of commerce. Chondrin is gelatine made from cartilage, and many gelatines contain it in considerable quantity; but we do not know that chondrin has really been chemically separated from gelatine, as different authorities give different formulæ as to its constituents, the same as they do for gelatine.

PAINTERS' CANVAS.—E. J. WALKER. We are unable to give the practical details of the preparation of artists' canvases. It is work we should scarcely advise a novice to undertake if the durability of the paintings put upon them is to be of any value. Ready-prepared canvas is supplied by the artists' colourmen in rolls at a very moderate price—probably for less than it can be prepared at home if time is of value.

LENS, TEST FOR.—C. JAMES. We must refer you to one or other of the works on Optics, say, the late Mr. J. T. Taylor's *Photographic Optics*. It would take up far more space than this column can afford to give instructions for testing lenses. We may, however, give you a practical hint. Take a negative or two of such subjects as you require the lens for, and judge from them if it is, or is not, equal to your requirements.

PHOTOGRAVURE.—B. S. WARDLE. As the Talbot patents were taken out nearly forty years ago, they expired many years since. Consequently you, or any one else, are at perfectly liberty to work either, or both, of his processes in their entirety, and without devising modifications to "get round the patents." The modern modifications of the Talbot methods, we may tell you, are not restricted by patents, their workers simply keep the working details of them, as they employ them, as trade secrets.

ALBUMEN ON GLASS.—STEREO. It is quite correct, as you say, that it is claimed for transparencies by the albumen process that they have never been surpassed, and the claim can well be sustained. The reason why the albumen process is not worked more by amateurs is that it is a process that involves considerable trouble in working, as well as considerable skill to obtain the best results. Even if the plates could be purchased ready for use, the same as gelatine ones can be, they would be but little used, as the development is quite different from that modern amateurs are familiar with.

UNMOUNTING PRINTS.—C. BARRETT says: "I have had some prints sent me to take off their mounts (rough cardboard) and remount them on others with a margin. I have soaked two of them in water for six hours, and they stick as fast as ever. I do not know what they were mounted with, and cannot learn. Can you suggest any way by which they can be got off?"—Most likely the prints were mounted with glue, or gelatine, in which case they should be soaked for some hours in cold water, and then transferred to warm water, when they will come off easily. If that fails, the mounts must be stripped off sheet by sheet, and the last one carefully rubbed off with the finger.

BUILDING.—PHOTIC-ART writes: "In laying down the bricks, &c., forming the foundation of a studio or glass house, what is the consequence in making the piers of bricks, placed upon each other with or without mortar or other binding material, so far as the landlord is concerned? I have been informed that, if mortar is used, the landlord of the property or land it is fixed upon can lay claim to the work, and defy you to remove any part of the whole structure built thereon; but that, if no mortar be used, you may remove the whole concern whenever you desire to do so. Is this so or not?"—We are not certain on the point, but we know that nurserymen's greenhouses are looked upon as trade fixtures, and they may remove them, but a private individual may not. We believe that, when a nurseryman removes a greenhouse, he leaves the brickwork upon which it has stood. Better consult a solicitor on the subject, or make an agreement with the landlord that you can remove the building at the expiration of the tenancy.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1875. Vol. XLIII.—APRIL 10, 1896.

Contents.

EX CATHEDRÂ.

Mr. E. H. Fitch, whose name has so long been identified with the manufacture of celluloid films, informs us that he has succeeded in taking photographs by the X rays (now no longer "X" rays if we are to trust the evidence of the report we reproduce in the following paragraph) in one second. He also informs us that he has perfected a new screen for direct vision purposes.

* * *

The London Correspondent of the *Daily News* states that Professor Winkelmann and Dr. Straubel, of the University of Jena, have succeeded in discovering a new method of photographing with Röntgen rays, by which the length of exposure is reduced to only a few seconds. "The method is based on a conversion of the X rays into rays of other undulations, by means of fluor spar crystal. If the Röntgen rays are allowed to fall upon a plate, the sensitised film of which is turned away from them, and covered with fluor spar, the rays, after passing the film, will be absorbed by the fluor spar, and there undergo the modification spoken of. The new rays now act upon the plate, and indeed much more strongly than did the Röntgen rays on passing through. As large fluor spar plates are to be had with difficulty, powder of the same crystal was tried in their place, and, as this succeeded, nothing stands in the way of the further application of the method. The new rays emitted by the fluor spar were minutely examined by the discoverers. They succeeded in determining their refrangibility, and from this the length of the undulations. The rays lie far beyond the ultra-violet end of the visible spectrum."

* * *

Among those who have been working hard with the New Photography is the versatile Mr. W. I. Chadwick, of Manchester, who has submitted to us several excellent specimens of his radiographical productions. We are gratified to find that our article of February 28, giving directions how to proceed about taking electrographs, as well as our advice to photographers to engage in this branch of work, has been of distinct service to many of our readers.

* * *

In sending us a print of the finish of the Inter-Varsity Boat Race, Mr. F. Gage, of Nottingham, remarks: "Just an untoned print sent you in a hurry, as I thought you would like to see it. Conditions so bad, I don't think there can be many photographs taken; but it is not bad, considering it was raining at the time. It is the tenth race I have done. If you measure boats, it is exactly two-fifths Oxford has won by. Good old Fenner judged very accurately. It was a glorious race. I was standing in water when I took it, and during the hailstorm was almost inclined to throw it up, but, although I got drenched, I think I am fairly rewarded."

* * *

Mr. Gage did very well, under the difficult conditions in which he had to work, the photograph being fairly well exposed and the view of the boats indicating their relative positions with sufficient exactness to enable every one to be able to check back the Judge's verdict. May we assume that in the not far distant future, photography, in athletic and other contests, will supersede the distance Judge, and will automatically and exactly record what is now, under the best of circumstances, largely matter of guesswork?

* * *

Messrs. Taylor, Taylor, & Hobson inform us that Cooke lenses, Series V., *f*-8 of 9 in. focus for 8 × 5 plates, and 11 in.

focus for $8\frac{1}{2} \times 6\frac{1}{2}$ plates, are now on the market. They also state that they have removed their London office to more convenient premises at Faraday House, 8 and 10 Charing Cross-road, W.C.

* * *

A WELL-KNOWN professional photographer, writing over the signature "One of the Crowd," sends us the following suggestion with reference to the provision, by the makers of gelatino-chloride papers, of those popular printing surfaces in various cut sizes. The suggestion has more than once been made already, and was not favourably received, but we again give it place, because, possibly on grounds of economy to the photographer, there is something to be said in favour of it.

* * *

"As a practical photographer of some thirty years' experience and constant user of this valuable recent addition to our printing processes (P.O.P.), might I be allowed to suggest to the makers of same the extremely advantageous improvement it would be were they to make a cut cabinet size $4 \times 5\frac{1}{2}$ inches, instead of (or in addition to) the size already listed ($6 \times 4\frac{1}{4}$), as, in my own practice, and, doubtless, that of most other professionals, this latter size is *no saving of time whatever*, having always to trim the paper on all sides to adapt it to the shape of the ordinary commercial cabinet mounts. It may meet the requirements of the amateur, but certainly not so the professional photographer, and an exact cut size in cabinets, &c., or to meet *his* requirements and fit *his* mounts, would, I venture to think, prove a boon and a blessing to most of us. I would also suggest the *dating* of sealed tubes of P.O.P., that the age of it may be known at a glance."

DIRECT HALF-TONE NEGATIVES WITH THE SCREEN.

SINCE that far distant date when, in October 1852, the late Henry Fox Talbot patented the first crude idea of what is now called the screen, vast changes and improvements have been effected, not only in the methods of using screens of various kinds, but also in their manufacture. In the patent alluded to, mention is made of "photographic veils," by means of which the "effect of engraved lines or of universal shading" was sought to be produced, and to attain this result "the image of a piece of folded gauze, or other suitable material," was impressed upon the plate prior to the formation of the photographic image.

It is noteworthy, in connexion with this, the earliest use of a screen, that it was applied to the plate previously to the production of the image of the object to be copied—noteworthy because quite recently that method has been revived, and made the subject of a patent as an improvement upon the now generally practised plan of forming the image of the screen and the subject to be copied simultaneously.

During the period that has elapsed since the date of Fox Talbot's patent, the changes have been rung very considerably on the screen method of translating continuous half-tone. Woodbury was the first, we believe, in comparatively recent times to resort to that system, his method being to use the photographed image of a piece of fine gauze netting; but, though fairly promising results were thus obtainable in an experimental way, the effect was in no way comparable with modern screen work. The first really practicable process in which the screen was employed was the secret one of Meisenbach, if we are not mistaken, and finely ruled lines for copying into screens soon became recognised articles of commerce, and these gradually developed into the diamond ruled screens of the present day, which, in point of perfection, it is almost impossible to expect to excel.

Before this degree of perfection had been attained, and before the true principle of the use of the screen had been recognised, numberless variations had been resorted to in the method of use in order to secure a, to some extent, selective grain; that is to say, a grain which differed in its fineness in different parts of the negative, according to the extent of the action of light. Thus, a part of the exposure was made without any screen at all, and then successive exposures were subsequently made, using the screen in different positions so as to obtain a result free from the excessive sharpness or "screeniness" given with the fixed position. Sometimes the screen was used simultaneously with the formation of the image of the subject to be copied, sometimes prior to or subsequent to its formation; sometimes a single-lined, sometimes a cross-ruled, screen was employed; in fact, almost every operator had his own individual plan of working.

It was not, however, until within the last very few years that the principle of the screen as at present employed began to be studied, and still more recently to be thoroughly understood; and even at the present time, judging by the different opinions expressed, it seems to be open to doubt still whether the diffraction, the pinhole image, or the vignetted theory, is the correct one. It is true that amongst the upholders of the diffraction theory are some of the most practical men of the present day, including Mr. Max Levy, to whom we are indebted for the perfection of our modern screens; but, although diffraction undoubtedly forms a most powerful factor in modifying the character of the dot obtainable on the photographic plate, it is still questionable whether its influence is very great under actual working conditions. A careful examination of Max Levy's examples of undoubted diffraction and of actual negatives used in half-tone printing will go far to strengthen this doubt, whereas the pinhole-image theory fits in almost completely with all the effects obtained in real practice under any of the working conditions of stop, screen distance, and camera extension.

But there is such a strong tendency, nowadays, to resort to complications in the shape of irregular and multiple apertured stops, that it is quite impossible to say how much of the effect is due to diffraction and how much to the combined influence of screen and stop; and it is almost equally difficult to work out, except by accident, almost the proper working conditions for any combination of circumstances. We were irresistibly led to this conclusion on perusing carefully a very elaborate paper, with diagrams, on the theory of the screen, by Mr. E. Deville, Surveyor General for Canada, who has given a vast amount of attention to this difficult subject. But, setting aside all the complications in connexion with different forms of stop and of "cross-line," or "chess-board" screens, we could not help being struck by his summary of the use of the vignetted screen. He says: "In theory, the vignetted screen is the most perfect one for photo-mechanical process, because correct prints can be obtained, from either thin or intense transparencies, by using thin or intense screens." And, again: "This method is unfortunately restricted to dry plates, otherwise it would be the best of the three." As to its being, in some respects, theoretically the best form of screen, we are quite at one with Mr.

Deville, though, in practice, we do not think it need be restricted to use with dry plates.

A vignetted screen, with any degree of "softening" that may be required, is very easily produced by any one possessing at the same time a diamond-ruled cross-line screen and the necessary skill to produce a collodion reproduction. It is simply a question of arranging size and shape of stop—which may be matters of individual taste—in conjunction with proper screen distance and camera extension, and exposing with the screen in position as for making a half-tone negative, only substituting a plain white, evenly illuminated surface for the subject to be copied. The result will be a screen, to use Mr. Deville's words, divided into minute zones of varying degrees of opacity.

Now, if, instead of making this screen on an unexposed plate, we substitute one, either wet or dry, that has been exposed in the camera in the ordinary way, but for a shorter time than would be the case for an ordinary negative—on, in fact, an under-exposed camera negative—the subsequent exposure through the screen will form a combination half-tone negative, in which the auxiliary exposure will, at one and the same time, make up for the under-timing of the first, and also supply the screen effect. By reason of the vignette effect in the screen exposure, the dots will vary in size in proportion to the amount of light action in the exposure on the subject itself, and so an identical, if not a more perfect, result will be obtained.

Mr. William Gamble, at the close of an interesting article in our number for March 13, says: "Hardly anything has been done in the use of the screen for photographing from life and from still objects. There is an immense field here, and it is not an impossible one to develop, but it will not be by existing methods." Here is a suggestion, or perhaps we may say "more than a suggestion," which scarcely requires more working out than the careful adjustment of the various exposures, and which entirely does away with the retarding action of the screen in exposures in the ordinary manner.

Science Popularised.—Evidently the tastes of the British public are becoming very different from what they were a few years back. Then the general public took but little interest in scientific matters, or at least included them in their frivolities. Clearly the case is different now, as we find two of the latest things that science has given us figuring at music halls. At one, demonstrations have been given of the Röntgen X rays; and at some others the Cinematograph is made a leading feature of in the programmes, and it seems to be highly appreciated by the audiences, if one can judge from the applause it receives.

A New Property of the Cathode Rays.—At the last meeting of the Paris Academy of Sciences M. Gouy mentioned a peculiarity of the cathode rays not hitherto observed by any one. Heating with a blowpipe a Crookes' tube which had been used a long time, he stated that the glass took the appearance of ground glass, arising from the development of a large number of imperceptible bubbles of gas. If the heating was continued, there were seen on the interior of the body of the glass little bubbles, formed by the union of those of more minute size. In the same way, glass, which has been exposed to an intense cathodic discharge, disengages bubbles of gas.

Permeability of Bodies to Different Radiations.—At the same sitting M. Becquerel gave an account of the relative penetrating power of the radiations from phosphorescing substances and the Röntgen rays. Using photographic plates and an electrometer, he obtained entirely concordant results. He said, in a general way, that bodies were more transparent to phosphorescent than Röntgen rays. Thus, platinum and copper, which are but slightly permeable to the latter, are very easily traversed by the former. Quartz, quite opaque to Röntgen rays, is transparent to phosphorescent radiations. Indeed, a layer of pounded glass is more transparent to the latter than pieces of clear glass of equal thickness. It is noticeable that powdered glass, by reason of the irregular internal reflections, is quite opaque to ordinary light.

Very little appears to have been done in this country with phosphorescent rays, and it is quite possible that these discoveries of M. Becquerel may to some extent explain some of the anomalous effects obtained by British workers at various times.

Amusing.—One of our evening contemporaries has a column devoted to queries, to be answered by any one who cares to write in reply. Those that from time to time appear in connexion with photography are frequently highly amusing, and so too are the replies that are generally given. Here is a query that appeared one day last week. "*Photography.*—What is the best and cheapest way to develop an ordinary negative?" Here is another that appeared on the following day: "Will any reader oblige with advice about how to start as an amateur photographer? Would an outfit be expensive? Is a dark room necessary? What appliances are really required? What are the cardinal rules of photography?" Possibly replies have been given ere this, but we have not had the opportunity of seeing them.

Sunday Opening of Museums, &c.—On Sunday last, the South Kensington Museum—including the Indian collections—and the Bethnal Green Museum were thrown open to the public from two in the afternoon till dusk. They will be open now every Sunday, as will shortly be the British Museum, the Natural History Museum, the National Gallery, and the National Portrait Gallery. These privileges are what one section of the public have been contending for many years past, and what have been as strenuously opposed by another section. However, the House of Commons, by a large majority, recently enacted that they should be opened. It now remains to be seen how the general public will appreciate the acquisition. Anyhow, photographic *employés*, and others whose avocations prevent them on other days, will now have the opportunity of seeing, and studying, the works in our national collections—both science and art.

Amateur Photographers as Patentees.—It has always been, and is still, a vexed question as to what constitutes an amateur photographer—where does the amateur end and the professional begin? Out of the large number of photographic patents applied for during the year, it is surprising how comparatively few are by professional photographers and apparatus-manufacturers. The larger proportion are taken out by amateurs. It is curious to note the callings of the various photographic patentees, such as "Clerk in Holy Orders," "Doctor of Medicine," "Architect," "Gentleman," &c. By the way, the last-named designation figures more frequently than any of the others. Last week the specification of a dark slide was published. The patentee is described as "———, M.A., F.R.G.S., Gentleman." Now, what is the object of patenting a thing but, presumably, to make money out of it, otherwise the expense would not be gone to? At one time, amateurs were only too pleased to give the world the benefit of any invention or improvement they might make, either in processes or apparatus. It seems now, however, that any little improvement—real or imaginary—however trifling, that the modern amateur may make is made the subject of a patent, with the idea of turning it to a monetary account.

A Simple Barometer.—Those of our readers desirous of paying some attention to weather changes, yet not caring to go to the expense of a barometer, may construct a substitute of fair

efficiency in the shape of what has long been known as a water glass barometer. If an ordinary boiling flask with a long neck (the old-fashioned oil flask, usually termed a Florence flask, will suffice) has a small quantity of water poured in and then inverted, and the neck made to dip below the surface of a vessel of water, the whole arrangement will form a weather glass, giving approximately indications of changes in atmospheric pressure. The water in the flask will partly fill the neck, and its height will vary according to the pressure of the atmosphere. It is, of course, subject to temperature variations, and so should be kept out of direct sunlight.

An instrument of more scientific precision is actually made for sale by the scientific-instrument makers; it is termed a sympiesometer. It is a glass tube with the upper end closed and formed into a bulb, the lower, turned up and widened out to make a cistern, and open at the top through a pipette which is supplied with a plug to close it when the instrument is required to be carried about. The upper tube is filled with air, and the lower with sulphuric acid, generally coloured to make it visible, which rises or falls in the tube, according to the air pressure. A carefully graduated scale is attached, which is made by comparison with an ordinary barometer. A thermometer is also attached, so arranged as to render the readings corrected for temperature variations.

Art at the East End.—On Wednesday, last week, Lord Herschell opened the Whitechapel Fine Art Exhibition. This is an annual Exhibition, organized by Canon Barnett sixteen years ago, and is highly popular while it is open, which is for, really, a too limited period—two or three weeks only. While open last year, the Exhibition was visited by over 62,000 people. This is a loan Exhibition, and this year there are nearly 250 works shown. They include the names of Sir E. Burne-Jones, Lady Butler, Turner, Wyllie, Vicat Cole, Sir J. Millais, Lord Leighton, Watts, Orchardson, Stacey Marks, Briton Rivière, and other well-known painters. Amongst the first-named artist's work is the series of *St. George and the Dragon*, and the *Golden Hairs*, lent by Lord Battersea. These works, it is said, the owner will not again allow to go out of his possession; therefore those who wish to see the originals of the subjects that Mr. Fred Hollyer has made us so familiar with in his fine reproductions should not miss the opportunity. The Exhibition is open daily, Sundays as well, up to and including Sunday, April 19.

There is another Fine Art Exhibition also open at the East End—at West Ham. This show contains about the same number of pictures as the Whitechapel one. Amongst the artists represented here are Lord Leighton, Sir John Gilbert, Watts, E. S. Armitage, Stanfield, F. Goodall, W. P. Frith, F. Walker, and other eminent artists whose names space will not permit allusion to. This Exhibition will, after a week or two, be removed to the Town Hall, Stratford, where it will be more conveniently situated for the majority of the residents at the east end of London. Both these Exhibitions are of pictures loaned from private collections, and this may be the only occasion that the public will have the opportunity of seeing them, therefore the opportunity should not be lost.

Ordinary Cameras for Eclipse Observations.—An extremely interesting series of suggestions were made by the President at the last meeting of the British Astronomical Association bearing upon the use of an ordinary camera at the forthcoming eclipse of the sun. Mr. Maunder said that, until his receipt from Professor Oudemann of a photograph which he had taken in 1871, and which he found contained valuable information, he had held the opinion that there was little to be done with an ordinary camera; but he had altered his opinion, and he stated that much good work could be done, at Vardsoe, by those who went with no other apparatus than an ordinary camera and lens of, say, twelve or fourteen-inch focus and upwards, a series of short exposures being given, a quarter of a second enabling sufficient sharpness to be shown. Before the successful camera work done by the Pacific Coast Amateur Photographic Association in the January eclipse of 1889, there had been scarcely a single photograph showing an extent of corona beyond fifty-five minutes taken; but some of the photographs taken by members of the Association considerably exceeded that range, and were valuable in accordance. The most essential point was stability at the moment of exposure, and, to attain this end, he recommended the use of an expedient tried in California with much success. The camera was bolted down to a plank, one end of which rested on the ground while the other was supported on a trestle. His idea was that the best plan would be a small stout stool made with its top slanting at an angle of fourteen degrees to the horizontal, and the camera bolted to that.

One of his remarks, however, if as reported, should be qualified. He is stated to have said that the ordinary portrait lens could have its focus increased by removing the front lens. What really is needed in such case is, when the lens is removed, to put it back again, but, in the place where the back lens usually fits; increased focus will then be obtained; but the lens left in the instrument after removal of the front lens of a portrait combination would be quite unsuitable.

The National Portrait Gallery now Open.—At last the National Portrait Gallery is open to the public, and why its opening has been so long delayed is a question with many. However, on Saturday last it was opened, and without any ceremony whatever. For many years this collection has been little less than a "white elephant" to the authorities, stored in the cellars of the National Gallery, taken to Westminster, some carted to South Kensington, some to Bethnal Green, &c. However, they are now permanently housed in their new home—that part of the National Gallery facing St. Martin's Church. The pictures are arranged somewhat chronologically, commencing at the top of the building. It is here they get the best lighting. In some of the lower rooms they suffer in respect to their illumination, some considerably.

There are something like a thousand portraits in the collection, and they date from the Tudor period downwards. In the assemblage are the portraits of kings, queens, divines, explorers, artists, statesmen, *et hoc genus omne*, and examples of the best work of most of the first portrait painters of this and past ages. Amongst the names may be mentioned Holbein, Sir Peter Lely, Gainsborough, Sir Joshua Reynolds, Romney, Richmond, Benjamin West, Watts, and many others whose work is peculiar to themselves.

Photographers will do well to study the work of the different masters to be seen in the Gallery, as from them they will find much to emulate, and, in some instances, what to avoid, in portraiture. Twenty years or so ago, photographers appeared to go to painters for their poses, columns, curtains, and the like. Now the case seems to be reversed; painters appear to go to the works of the best photographers for their poses, as witness the portraits shown in recent Exhibitions of the Royal Academy, and other leading shows. In many of those pictures, not only is the pose copied, but nearly the whole picture has been painted from the photograph.

THE PHOTOGRAPHIC NATURALIST.*

Photography and Vulcanology.

The careful series of drawings, made in 1767 by Sir W. Hamilton to illustrate the building up of the cone of Vesuvius, would have been far more complete if photography could have been employed to supplement the hand sketches. It was not, however, until the eruption of 1872 that any extensive series of photographs of this interesting volcano were made. In that particular series we have illustrations of the lava streaming down the flanks of the mountain, together with clouds of steam and dust rising from the crater to the height of 20,000 feet. Dr. Johnston-Lavis is now able, by almost daily photographs of Vesuvius, to chronicle the rapid changes which it undergoes, as well as the aspect of the crater both before and after

* Continued from page 182.

an eruption. Some valuable information has also been secured in Hawaii by means of a series of photographs taken at short intervals during the advance of a lava stream.

In the library of the British Museum will be found a book published in 1856 by Mallet, and illustrated with a series of photographs, taken by that famous vulcanologist himself, to illustrate the various phenomena produced by the Naples earthquake; but photography has more recently been employed in the far more delicate study of earth tremors or seismology. In 1887, Fouqué and Michel Levy made a series of experiments on the rate of transmission of earth tremors. A reflected beam of light from a mercury dish was focussed on a sensitive plate revolving in the path of a lens. In the absence of any earth movement a circle was produced on the plate, but the smallest vibration caused a widening of the circumference, indicating the beginning, duration, and end of the shock.

A photographic tremor recorder or seismograph was described in 1892 in the *British Association Reports*. A beam of light from a vertical slit was made to pass through a lens to a mirror, and thence to a horizontal slit behind which a photographic plate moved vertically by clockwork. Continuous daily observations were taken on plates, twelve inches long by two and a half inches wide, moving slowly in twenty-four hours across the slit. By a more rapid motion even tremor storms were indicated. Professor Milne used a similar method, by connecting a galvanometer to a deep well, to record changes of electric potential in the earth during the progress of an earthquake. The frequent Japanese earthquakes have given Professors Burton and Milne an opportunity of securing photographic records of the utmost value in the study of seismology.

In connexion with this subject, it may be mentioned that the ordinary seismograph records on smoked glass are conveniently copied for permanent preservation upon cyanotype paper.

Subterranean and Submarine Photography.

The first subterranean photograph was taken in 1865, and shown to the British Association by Mr. A. Brothers. It was a view of the Cupola Cavern, Blue John Mine, Derbyshire. In the same year the first coal-mine photograph was secured by Jackson Bros. of Oldham, and Piazzi Smyth photographed the interior of the Egyptian pyramids. All these, as well as Anthony's series of photographs of the Mammoth Cave, accomplished in the following year, were taken by means of magnesium ribbon.

Since the introduction of modern dry plates, the facilities for subterranean photography have greatly increased. Sopwith's series of photographs, illustrating coal mining, were obtained in 1881, the light from burning magnesium ribbon being concentrated by parabolic tin reflectors. Both coal and metalliferous mining have lately been well illustrated by Messrs. Burrow and Hughes, whose experience has been chronicled in papers read before the Royal Photographic Society and elsewhere. The peculiar difficulties of this department of photography are well shown by the fact that less than twenty per cent. of the negatives taken by them were good, and seventy per cent. were complete failures. The difficulties arise chiefly from the imperfection of illumination, especially in coal mines. The smoke from blasting and the moisture of the atmosphere are also obstacles to success. The woodwork of the apparatus becomes swollen and stiff, while the lens becomes rapidly dimmed by condensed moisture, and must be examined immediately before exposure. A preliminary rubbing of the lens with glycerine diminishes this evil. If magnesium ribbon is used for the purpose of viewing the picture before exposure, care must be taken to let the smoke clear away before uncapping the lens. Focussing is better done by means of candles placed in various positions in the field of view. The lens which Mr. Burrow found most suitable was the Zeiss anastigmatic, *f*-7·2, and for confined spaces the Ross concentric, *f*-22.

As regards underground lighting, the following are some of the advantages and disadvantages of the ordinary artificial illuminants:—

1. *Electric Light.*—The arc light gives good results, but is seldom available. It is not suitable for miners at work on account of the long exposure necessary. A sheet of white paper behind the light forms a good reflector and relieves the half-tones. Incandescent lamps have been proved to be useless for underground work.

2. *Bengal Fire.*—This gives a brilliant white flame, but the fumes discolour stalactites, and the sulphurous smoke not only dims the atmosphere but is dangerous to inhale.

3. *Magnesium Ribbon.*—The light from this source is somewhat uneven. A long exposure is necessary, and a heavy smoke is produced, which is of great inconvenience where there is bad ventilation. It is better when burnt in oxygen gas.

4. *Flashlight Powder.*—Most of these powders are dangerous to use, as they explode on percussion and give irrespirable combustion products. The following composition has been recommended as giving an intense light, visible at a distance of 100 kilometres:—Magnesium powder, 20 parts; barium nitrate, 30 parts; flowers of sulphur 4 parts; and beef fat 7 parts. The fat is added in a melted state to the mixture and cooled in zinc boxes. A charge of half a kilogramme burns for twenty seconds.

5. *Magnesium Powder.*—This is the safest of all flashlights, giving but little smoke, and requiring but a short exposure if burnt in a suitable lamp. Messrs. Hughes and Burrow prefer the Platinotype Company's lamp. Magazine flash lamps are now to be had containing enough powder for twenty ordinary flashes. By this means successive flashes can be given if necessary from different positions to relieve the shadows. A large quantity of the powder should be used for each flash to secure full exposure.

Of course, only the quickest plates should be used, and development should be slow, with a diluted developer to avoid hard contrasts. It has been suggested that, for proper illumination, the greater source of light should be placed at a short distance on one side of the camera, and a lesser source, or shadow softener, above the lens. To prevent smoke and ashes from being thrown in front of the lens, a lamp with a vertical flame, rather than a horizontal one, is to be preferred.

Submarine photography has not been very extensively practised, although various efforts have been made to accomplish this end. In 1866, M. Bazin described a complicated arrangement for photographing the sea bed. It consisted practically of a diving bell, from which the operator took photographs, by electric light, through strong glass windows. More recently, M. Bontan, of Paris, has obtained excellent photographs of the bottom of the sea, by means of a submarine camera, consisting of an ordinary hand camera enclosed in a watertight metal box, with plate-glass sides. In shallow water ordinary daylight suffices but in deep water the operator descended in a diving dress, and used the magnesium flash light. A blue glass screen in front of the lens was found advantageous.

An ingenious contrivance for finding the direction of submarine currents and their temperature was submitted in 1874 to the Berlin Geographical Society, by Dr. Neumeyer. The camera consisted of an hermetically sealed copper box, containing a thermometer and a compass needle. The box had a rudder attached to it, causing it to lie with the current, while at any given moment the temperature and compass bearing could be imprinted on a sensitive surface by means of an electric arc light. These experiments are of interest, when we remember the great difficulty surrounding all submarine observations and the persistence with which the resources of photography are employed to overcome natural obstacles.

Museum Photography.

There is at the present time a growing tendency to illustrate geological text-books with process blocks made from photographs of selected museum specimens. In order to make such reproductions really effective, great care is necessary in arranging the light and shade. In general, a vertical aspect is necessary, for which purpose the special stand with glass platform, described in a former article,* will be found convenient.

Quite recently, Messrs. Sharp & Hitchmough have manufactured a special museum stand and camera to meet the requirements of the Liverpool Museum authorities. The stand is meant for use, not only in the museum but also in certain cases in the field, where fossils or minerals are required to be represented *in situ*, in awkward positions for the ordinary camera. It can be used with equal facility for photographing objects in a horizontal plane, either above or below the level of the camera, the camera itself retaining its normal position. A forward extension enables the lens to be brought directly over fixed show cases, and a prism placed between the lenses enables objects in the horizontal plane to be readily accessible. An adjustable glass platform, with a reflector below, is useful for supporting solid objects, without the danger of cast shadows, and at the same time, allowing backgrounds of suitable colour to be employed. This apparatus possesses all the advantages of the vertical camera, previously described, without the inconvenience arising from the difficulty of focussing in the vertical position.

The vast collections of splendid specimens of minerals and fossils stored up in our museums would be rendered of far greater educational value if such a camera were at the disposal of those wishing to secure either book illustrations or lantern slides for lecture purposes.

All photographs of minerals or fossils should possess some simple

* The British Journal of Photography, vol. xlii. p. 42 (January 18, 1895).

means of estimating their natural size, either by an attached scale, or by placing by the side of the specimen some familiar object of known magnitude.

In many cases, a known distance can be marked on the specimen itself by means of two small discs of white paper, while paper arrows properly disposed can be used to direct attention to any special feature which the specimen illustrates.

Photographs of Rock Sections.

The quantitative mineral analysis of a complex rock by chemical means is at all times a difficult process, and often quite impossible. A ready means of arriving at an approximate result, however, when not too fine grained, is afforded by the simple device of photographing a thin transparent section of the rock.

After cutting out the various crystals from a paper positive and sorting them, their relative proportions can be determined by weighing the different samples. This is more accurate than the plan advocated by Delesse of drawing the outlines of the crystals by means of the camera lucida.

To photograph a rock section, it often happens that only a moderate enlargement is necessary. A microscope need not then be used, as a magnification of from two to five diameters is readily obtained by the ordinary camera in conjunction with a wide-angle lens. A symmetrical lens of short focus, about two inches, for instance, answers very well, as did the small Petzval postage-stamp lenses of an inch and a half focal length formerly in the market. A long extension or lengthening cone is necessary. In the absence of a lens of sufficiently short focus, the best plan is to obtain a photo-microscopic attachment for the camera, consisting of a simple arrangement to carry the objective, and an adjustable stage for the rock section. For illumination the ordinary microscope lamp will do when low powers only are used.

Sometimes a better contrast is obtained in photographs of rock sections by using the polariscope, in which case isochromatic plates and monochromatic light are beneficial. Occasionally it may be found that a rock section is too coarse and opaque to give good results on magnification with the camera. In this case, the section can itself be used as a negative, and a print obtained by contact on sensitive paper or on glass, and from this the positive picture can afterwards be prepared and enlarged to any size.

It is not proposed here to enter into the domain of photo-micrography proper required in more advanced petrographical work with high powers, as this subject can be more conveniently treated in a subsequent article.

Conclusion.

Probably there are few geologists who have not had occasion to regret either the loss of time involved in making hand sketches of interesting geological subjects, or, what is still more important, the inadequacy of the result to represent the desired effect. In photography we have a simple means of overcoming both of these difficulties. But the value of a geological photograph is largely increased if it is accompanied by an outline hand sketch, showing the details intended to be expressed. This is done with great effect in the geological photographs displayed in the Museum of Practical Geology in London, which also illustrate in a striking manner one of the great advantages of a photograph over a hand sketch for educational purposes. Hand sketches show only that to which attention is desired to be drawn. Whether it be a fault, a contortion of strata, or an igneous dyke, a single glance is enough to reveal the whole object of the drawing. The consequence is that a student is disappointed on first commencing field work to find nature not so plain as the diagrams in his text-book, since the features he is looking for are often obscured in the field by a mass of secondary detail, which he only learns how to eliminate by practice. With a photograph the case is different. The eye has to search the photograph for the required feature as diligently as the field geologist searches the face of the cliff or the side of the cutting, and the student derives from the study of photographs a preliminary practical training which is invaluable in his future field work.

But another advantage often to be derived from the study of geological photographs places them in one respect even before nature herself. Structures which easily escape notice in the field are brought into prominence when condensed by the lens into the small area of a photograph. In this way minute contortions, the angles of intersection of jointing planes, the angle of dip of strata, the presence of obscure bedding planes, and other important features, are more accurately detected in a photograph than in an actual section. Perhaps the question may arise in some minds as to what is a geological photograph, and how may it be known to be worth preservation. In one respect all photographs of natural objects are geological photographs, and it is impossible to say how soon a photograph, now about to be discarded, may prove of inestimable value to science. Change and decay are going on around us in the inorganic as well as in the organic world. The agencies of denudation rapidly alter the aspect of the country; interesting sections become overgrown with vegetation or buried by the *débris* of a winter's frost; volcanic forces destroy the shapes of mountains, and visit even men and cities with sudden destruction; fossils found perfect *in situ* become broken during extraction, or perish subsequently in the museum or cabinet from the oxidising action of the atmosphere. No natural feature can be looked upon as lasting, and science calls aloud for the duplication of valuable evidence while there is yet time. It is true that photography is as yet too young a science to have proved the absolute superiority of its records to the ravages of time; but we have photographic processes at our command which, if they do not give us imperishable results, are at least more permanent than the mountains and the plains, and which possess, moreover, this inestimable advantage, the power of being reproduced. J. Vincent Elsden.

PHOTOGRAPHIC WORKERS AT WORK.

III.—How Messrs. Wellington & Ward Make Bromide Paper.

Like the monks of old, makers of plates and paper—we could not help thinking as we entered Messrs. Wellington & Ward's premises in the picturesque little village of Boreham Wood—seem to select the most charming localities they can find for the scene of their labours. For the cause of this reflection, one need only pay such a visit as that referred to, and Messrs. W. & W. are by no means alone in this respect. If the classic neighbourhood of Ilford does not appeal to us as strongly as it does, doubtless, to, say, Mr. George Davison, on the score of beauty, at least, Barnet, Ashtead, and Richmond, to name three other of the homes of the dry-plate and paper trade at random, would hold their own for rural beauty with any three districts within fifty miles of London.

With some such envious meditations we entered the factory, a substantially built structure, complete in itself, but obviously designed with a view to facilitate future extensions, and found ourselves face with Mr. J. B. B. Wellington and Mr. H. H. Ward, partners in the business, and Mr. E. A. Allom, their manager in the office. It may interest our readers to know that, while enjoying the advantage of Mr. Wellington's experience of emulsion-making and photography generally, Mr. Ward is well fitted, both by taste and training, for engineering work, and no small number of the fittings and appliances in use in the factory are both designed and made by its proprietors.

In our tour through the various departments into which the buildings are divided, we were accompanied by Mr. Wellington himself, who led the way first into his laboratory, where also are kept the chemicals, &c., for the manufacture of the firm's various emulsions. A laboratory is generally most interesting to whoever has to work in it, and the one in question was no exception to the rule, the most attractive of its contents being a few bags of nitrate of silver, which required no small exertion to lift. Having lifted them—in the English, and not the Highland, sense—we pass out from the laboratory into a room devoted to emulsion-making. This room, and indeed the whole of the factory, is provided with non-actinic light by means of large wooden, boxlike structures containing a gas jet, and having their sides enclosed with golden fabric, giving a safe and pleasant light. In one corner of the emulsion-room stands a centrifugal separator, geared to the shafting above, while by its side is one of the huge earthenware emulsion mixers, quite large enough for a morning "tub."

While appreciating fully the method of speed determination of Messrs. Hurter & Driffield with which he has worked, Mr. Wellington tells us that he employs a modification of the Warnerke sensitometer to satisfy himself as to the progress of any particular batch of emulsion; and, while saying this, he shows us his sensitometer in which the trials are made, the plates which are exposed wet being prevented from coming into contact with the tablet of the instrument by means of three pins at the sides.

It is in this room that the emulsion is made, being then transferred to one of two rooms leading out of it, which is provided with a series of copper tanks with lids, under each of which, and enclosed with brickwork, is a series of large Bunsen gas burners. This is the cooking or boiling room, and the jars of emulsion, being removed to the tanks, are then heated to obtain the desired speed in the product.

The other room mentioned above is the washing room, where also is the stock of emulsions ready for coating. The jelly-like mass which the

emulsion presents when it has been allowed to set after boiling, is here cut up into shreds, and exposed with constant agitation to the action of running water, until all the soluble salts are removed. The washers in which this process is accomplished are seen like large barrels arranged over tanks all down one side of the room, and connected by belting with the shafting overhead.

From this department the finished emulsion, after being remelted, is taken to the coating room, to be spread upon the paper which is there waiting to receive it. The paper arrives in large rolls, each about 1500 feet long, and containing no less than 5000 square feet of paper. The process of coating seems of the simplest possible nature. A roll is mounted on the machine, the paper passed round two or three rollers, a stream of emulsion is run into the trough, and the machine started. Away goes the paper, and in three hours there is three-quarters of a mile of bromide paper hanging in festoons all along the room in which it is dried. The coating, drying, and rolling up, is done in what may be conveniently considered as one large room. At one end of this stands the coating machine, in which the paper is led round a silver-plated cylinder, the bottom of which dips below the surface of the emulsion in a plated metal trough, underneath which is a hot-water vessel to keep the contents of the trough liquid, and at the right temperature for coating. As the paper leaves the trough, it is led away at once over a series of rollers to a machine which forms it into long festoons as fast as it is coated, and conveys these festoons away from the coating machine until the room is full.

The quantity of emulsion spread upon the paper is determined by the rate at which the paper-coating machine is driven. The slower the paper band travels through the trough, the thinner the coating which remains on it, and *vice versâ*.

When the coating room is full, the operation is stopped, and the paper left hanging up to dry, which it will do completely in from four to eight hours. To facilitate this operation, the floor of the chamber carries a number of hot-water pipes, and cold air from outside the building is admitted along the edges where the walls meet the floor. From the top of the room three large fans exhaust the moisture-laden air from the room, and so set up a steady current through it, which ensures rapid drying. We might mention, in passing, that the whole of the factory is ventilated in the same way by means of fans and large wooden ventilating shafts, which are seen up against the ceiling of the various rooms.

As soon as the paper is dry, the end of it which was first coated is led into a winding machine at the other end of the coating room, and, the winder being started, it is wound up into a roll similar to the uncoated one, which was first placed in the coating machine, the three-quarters of a mile of paper being wound down in about forty minutes, the operation being quicker than coating.

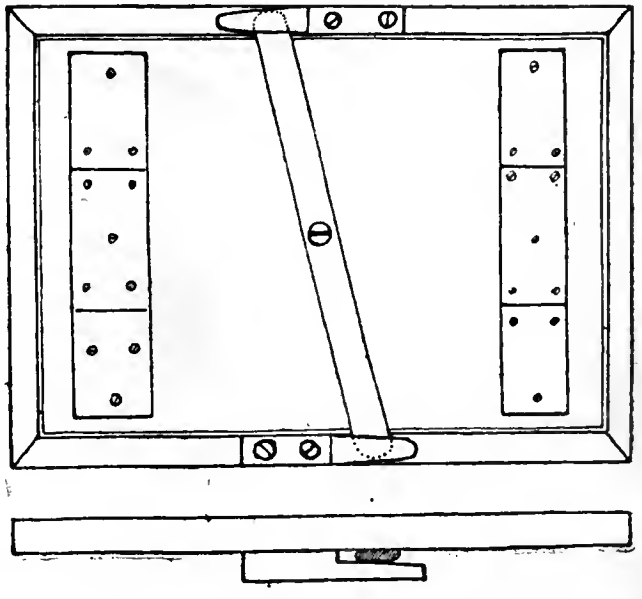
These rolls are then taken away into a store room until wanted, or, if required at once, are conveyed to one of the cutting machines, and there cut and packed. Two patterns of cutting machinery are in use at the Elstree factory; one is the well-known guillotine, which needs no further mention here, and the other a combination of the guillotine principle with that of a slitting machine. In this latter the roll of paper is inserted in the apparatus, and the paper passes between guiding rollers, and thence between two spindles placed some little distance apart, but bearing, at distances which can be varied, circular wheels or discs with sharp edges, the diameter of which is such that the sharp edges of the discs on the two spindles just meet. Between the edges of these discs the paper is led, and is by them cut up into strips much in the same way as it would be cut by a pair of scissors. These strips then pass to the guillotine portion of the machine, where they are again cut up in a direction at right angles to the first, the machine automatically ringing a bell when each dozen pieces have been so cut. In this way—supposing, for example, 10×8 pieces are wanted—the strip of paper which on the roll is forty-one inches wide is first sliced up by the discs into four strips ten inches wide, and these are in their turn cut up by the guillotine into eight-inch lengths.

This is the room in which the packing is done, for which purpose it is provided with long tables, behind which at intervals are the wooden, non-actinic lanterns previously referred to. The lads who do the packing each work opposite one of these, and, after examining each sheet to see that it is free from blemishes of any kind, wrap them up in dozens, and enclose them in the familiar envelopes in which the paper is sold.

From the packing room we pass into the storeroom, where the stock of the finished article is kept to supply to customers. This room is provided with plenty of shelf accommodation, but requires no comment from us. It is here that we once more emerge into daylight, which we left on entering the emulsion-making room, and a door in the packing room leads directly into Mr. Wellington's laboratory, whence we started. The various rooms in which the processes are carried out are arranged in a series going entirely round the factory, the first and final stages of the manufacture being conducted in rooms adjoining one another.

It was in the laboratory that we were shown specimens of the new film upon which Mr. Wellington has lately been concentrating his attention. Its manufacture resembles very closely that of the bromide paper just described, but is more elaborate, the series of operations having to be repeated three times to make the finished film. The paper is first coated with the preparation of gums, which allow the film bearing the image to be subsequently stripped from its paper support, and after this treatment receives a coating of the insoluble gelatine which forms the substance of the film itself. It is not until this has been applied and has dried that it is ready for the application of the sensitive emulsion, so that the new film undergoes three distinct coatings and dryings. At the time of our visit, a large batch of emulsion was in course of preparation for the film, and we had the opportunity of seeing this tested in the laboratory, with the very satisfactory result that indicated that the batch was a clean, bright one, giving a reading of at least 25 Warnerke, with plenty of density and pluck.

So far, all the operations have been conducted on the ground floor; but, before leaving the factory, Mr. Wellington takes us upstairs into the large lofts, which are above the rooms below, and which are mostly used as supplementary stores, but one is fitted up with sinks, &c., as a dark room. It is here that large quantities of bromide prints are turned out daily for use for advertising purposes, and we noticed several ingenious little labour-saving dodges being used for the purpose. The paper is kept packed flat in boxes with hinged lids, each of which is provided with two divisions, one for unexposed, and one for exposed, prints, development being effected only when a large number of prints are ready for the operation. The printing frames used are made on the premises, and, as shown in our sketch, are a simplified form, rendered possible by the paper, which is printed by gaslight, not requiring examination during the operation. The back is therefore in one piece, and is kept flat by means of two stays being held in position by a single bar which is wedged up at its two ends under two projections provided for the purpose, the shape of which can be gathered from the side view which we give.



Printing frame for bromide paper.

On leaving the factory to go to the station, we pass by outbuildings containing the hot-water arrangements for heating the building, the motive power in the shape of a four-horse-power gas engine as well as a blacksmith's shop, and other conveniences, and, bidding adieu to our courteous guide, once more the feeling of envy comes over us that our lines are hardly cast in such pleasant places as are those of the plate and paper-makers.

ON THE PRINTING OF SINGLE FIGURES IN GROUP NEGATIVES.

II.

In a previous article I referred to the printing of such figures in group negatives as did not require any alteration of the existing background; in which case, by merely providing a mask of suitable size and shape, the original negative was used for the purpose of printing, and, in cases where the size of figure was too small, a slight enlargement of same was easily made by any of the practical methods of enlargement direct on to any of the excellent platino-bromide papers which are so useful for the purpose.

In the majority of instances, however, it will be found that, owing to some overlapping of the figure, such as by a portion of the dress, or face, or figure, immediately beside the one it is desired to extract, the original background, of which such will form a part, becomes quite unsuitable for printing by means of merely masking the face and bust, and, when this occurs, the operation which we are considering is not nearly so easily performed, recourse having to be had to some method of dealing with the case whereby the undesirable background and surroundings have to be removed and others substituted for the same.

Of the various methods of accomplishing this end, perhaps there is none more practical or so certain in the results achieved as that of treating a paper print containing the figure, and not working on the negative at all. The method I am about to describe used to be practised in the good old collodion days, and, if neatly gone about, will produce very excellent results indeed.

Whenever, therefore, any figure has to be extracted from a group negative, and a different background has to be introduced, let the negative, or that portion of it containing the figure, be printed with much care on ordinary albumenised paper. In making this print, every attention should be bestowed upon the work, so as to produce the best possible result *for the purpose of copying*, with a view to the production of another negative of the size it is desired the finished picture to assume. Much of the success in the operation will depend upon the character of the print that is thrown off from the original negative.

In this print, of course, the undesirable background will appear, but it is easily removed, and a plain one substituted, by carrying out the following plan:—

Provide a suitable water-colour pigment for the purpose of painting out the entire surroundings of the face and bust. In my opinion, the most desirable tint to employ for this purpose is a good slate colour, and this is easily acquired by mixing proper quantities of flake white and ivory black, so as to yield a body sufficiently opaque to completely obliterate the design on the surface of the print.

In undertaking this blocking-out operation, a word of caution is required. It is no use attempting such work with the aid of any cheap rubbish in the way of the colours used. The very finest samples of the colours I have mentioned must be employed, and for this reason, that, in applying the slate tint to the face of the photograph, not only must it be sufficiently opaque to entirely stop out all the original background, but it must, when laid on, be of such quality as will permit of its being flattened down on the surface of the print in such a manner as to show a beautifully smooth surface, free from all streaks and rugosities, so as to permit of a clean, even background in the copying negative. To obtain this smooth surface on the print, the very finest samples of colour must be used. Cheap trash will not work in anything like the same manner, and, when used, are certain to end in failure. Some idea of the value of the two colours I have mentioned may be obtained when I state that small cakes of such, made by our leading colourmen, cost 8*d.* each. With these on hand, any one can approach the work with a tolerable amount of assurance of success.

To prepare the tint required, let a few drops of thick gum be placed on a clean opal slab, the rough side of which is best; into this rub alternately the white and black pigments until a good slate tint is produced. A suitable print having been obtained and mounted on a firm support, let the colour be carefully applied round the outline of the face and bust by means of a fine brush. To do this neatly, I advise any one whose eyesight is not particularly good to obtain a strong pair of spectacles—say, those of about nine inches. The use of spectacles for this purpose is much to be preferred over a hand magnifying glass, for the simple reason they leave both hands free, and permit of the work being done with much greater comfort and ease. Some workers may imagine they can do as good work without spectacles as with them. This is a mistake, however. There is no doubt about it that the aid of magnifying glasses permits of very much finer and closer work being done with the brush than when such are not used. And just here it should be mentioned that, seeing the work has to be somewhat enlarged at a later stage, the necessity of the utmost care being observed in blocking out the outline will be apparent to any one.

Having gone carefully round the edges of the figure, the colour must then be evenly applied all around, and if the proper amount of gum has been used in mixing them on the slab, when such is carefully applied, so as to avoid streaks, the pigment will settle down beautifully smooth, with a somewhat enamelled surface, like the rest of the albumenised surface of the paper.

When such is accomplished, the figure, with the new background, is copied on a suitable plate to the desired size, and the negative so obtained, being varnished and retouched, is ready for printing by any of the most approved or desired methods, a vignetted bust being among the best styles to adopt.

By the method I have described most excellent results are obtained, and it has also this further advantage, that in cases where only a paper print exists, containing the figure it is desired to extract, the treatment does not injure the photograph in any way, for, by merely rubbing the surface of the print after the colour has been applied and the negative made, the water colour will vanish, and not the slightest trace of it remain or any injury to the surface of the print be apparent.

There is, however, another method whereby the same results may be arrived at; but, in my opinion, it is not so easy of accomplishment as the one I have described. I refer to the blocking out of the background in the original negative by means of some opaque medium, and then printing the blocked-out figure in the usual way. This leaves the image resting on a blank, white background. To print in a tinted one, recourse must again be had to shielding off or blocking out the image on the face of the print.

Where only one copy is desired, and that of the same size as the original, the image may be covered up with any suitable water-colour pigment, such as gamboge, and, when this is carefully painted over the image, and allowed to dry, the white background is tinted down by means of a vignette shape, after which the gamboge will wash off when the print is placed in the washing water prior to toning operations, the parts where such was applied being in no way injured, and eventually toning the same as if such had never been applied.

A very slight consideration of these two methods will be needed by any one to see that of such the former is by far the best to employ, and for these reasons, that, with much less trouble, an enlarged negative is produced, from which any amount of similar prints may be pulled, only one operation of blocking out being required. By the latter method, when more than one print is desired, every print has to be shielded with gamboge, and this in itself is not easily performed, frequently yielding prints with a white streak round the outlines, caused by the slightest overlapping of the gamboge.

Some workers, instead of blocking off the printed image by means of gamboge, use a cut-out disc printed from the same negative, and shield the image with this; but the difficulty here lies in being able to cut accurately to the outline, and, even when such has been done, a further trouble ensues in the shape of being able to correctly superimpose this cut-out disc over the image whilst the background is being tinted.

Some workers who have never practised retouching may think that what I have described entails a lot of expertness, which only professionals are capable of accomplishing. Such, however, is not the case. Any one tolerably proficient with a brush will, with the aid of spectacles and the best quality of colours, be enabled to follow round the outlines of any figure without overlapping, and accomplish a very neat and useful feat in photogrsphy with absolute certainty of success.

T. N. Armstrong.

RADIOGRAPHY.

Perhaps this title may commend itself for permanent adoption to describe the new form and additional means of extending physical research.

The question which waits for an answer is the cause of the latent effect which can be rendered visible by any suitable photographic developer. A.—Is it the direct transmission of the extra refrangible or so-called chemical rays through substances which, though opaque to ordinary light, are sufficiently transparent to these chemical rays as to be able to cast shadows of the more opaque bone and metals, and yet able to pass comparatively freely through flesh and organic

tissues; B, or is it due to the effect of these rays in stimulating a fresh set of light waves, producing the fluorescent effect, the latent image being due to the photographic property of the fluorescent light? If either A or B is the correct solution of the problem, we might with some reason regard it as a new phase of true photography. Now, let us consider, and see how far we are justified in making this assumption.

C. Captain W. de W. Abney suggests that the glass carrying the sensitised gelatine might be capable of fluorescing in the X rays, and thus produce the developable shadowgram, and in support of this hypothesis points out that the latent image of these shadowgrams makes its first appearance next to the surface of the glass, and not on the naked side of the sensitive gelatine. And, further, it is stated that, if a ferrotype plate coated with a collodion emulsion be substituted, the X rays so far do not produce shadow photographs. The two plates being alike in sensitive salts, the difference between the two being the surface upon which they lie—and the vehicle in which they are embedded—and, finally, glass fluoresces in these rays, and metals do not, and so far a very strong ground for the assumption is made out, were it not for an equally strong claim being set up by the theory of electrical molecular bombardment and stress.

D. In support of this, Professor J. J. Thomson's experiments with the X rays may be adduced. This gentleman has found that these rays will readily discharge an electrically charged surface, and considers the effect of these rays to be far more readily felt by an electrometer than by a photographic plate, whilst a developable image is readily produced by electrical stress.

E. In order to test these two theories, I would suggest to those gentlemen who are actively engaged with radiography to try the following: Employ a celluloid film, instead of glass plates.

If a shadowgram be obtained, then A or D are indicated, the latent image is either the result of the direct photographic power of the X rays, or due to electrical stress.

F. But if no picture is obtained, then B, the fluorescent theory, seems to be indicated—because the celluloid support of the sensitive gelatine film is not fluorescent. To prove this, take another celluloid film and coat the back with a fluorescent substance, such as fluorescing quinine, or esculine, or a sheet of uranium glass, may be placed in contact with the celluloid back. If thus prepared, a shadowgram is obtained. We may safely assert fluorescence to be the correct explanation with some amount of reason.

G. The fact of the ferrotype plate not receiving any impression can be explained both by B and D, and, if a celluloid film behaves in the same way, B is indicated more completely; but the mere fact that a metal coated with a sensitised film does not produce any developable image is equally capable of explanation under the electrical theory.

The sensitised film is a very poor insulator, in fact for this purpose may be considered a good conductor of electricity, whilst the metal plate in contact with every part of the film equalises the potential, and uniformly discharges the electric energy. Under these conditions, there is no cause for wonder that the ferrotype plate is unacted upon by the X rays; but, if a celluloid film will receive a latent image when the ferrotype plate does not, D only is indicated, because, whilst the celluloid plate is an insulator of electricity, it is not a fluorescent substance.

For the electrical effect we require an insulator such as glass and celluloid, both good dielectrics, which are capable of absorbing to a certain extent electrical pressure.

To illustrate what I mean, let a perfectly clean and dry sheet of glass be coated on one side with tinfoil, and on the other let a printed bill be laid face downward upon the glass, leaving a sufficient margin of clear glass all round for insulation, then place a sheet of metal upon the printed bill. Now connect the tinfoil to one terminal and the metal sheet to the other terminal of the secondary of an induction coil, allow sparks to pass between the points for a short period; one or two minutes is amply sufficient, then disconnect and remove the metal plate and the printed bill, and gently breathe upon the glass. The whole of the printed matter will appear upon the surface of the glass. If the tinfoil be removed, the plate may be suspended, and for a considerable time will show an impress of the whole of the printed matter in clear and frosted glass, when breathed upon. The glass surface may even be cleaned with benzole, and polished with a clean leather, still it will retain its power of reproducing the impress each time it is breathed upon, the explanation being probably that organic particles from the printing ink are actually embedded beneath the surface of glass, and defy removal by the benzine solvent; or, that the printing ink is an insulator, and the absorbed charge in the glass under the letters is not discharged when the paper bill is removed. Benzole, being a good insulator of electricity, would not therefore remove the charge from those portions of the dielectric protected by the printing ink, whilst the rest of the glass, being in contact with the more or less humid paper, would be discharged, and, upon breathing on the glass, the undischarged portions of the surface of the dielectric collect and hold the moisture, whilst the discharged portions allow the moist vapour to dry off.

If a glass plate with a sensitive emulsion be employed, then a negative of the bill is produced, from the greater amount of molecular disturbance taking place between the insulating letters; whether this be the correct explanation of electrography or not, we have ample evidence that variations of electrical stress have the power analogous to light of producing molecular disturbance, separating the haloid from the metal, in due proportion to the relative intensity of the light or variation in the amount and degree of electric pressure.

FREDK. H. VARLEY.

OVER-EXPOSURE AND CHLORIDE RESTRAINERS.

MR. DEBENHAM'S recent paper on the treatment of over-exposure is in many respects instructive, and the account of his experiences cannot fail to interest those who are on the outlook for fresh information on the important subject upon which he writes.

There is, naturally enough, a considerable diversity of opinion among photographers in regard to the manner in which over-exposure should be dealt with. Though the ordinary bromide restrainer has met with well-nigh universal acceptance, there are few who, at the present day, will refuse to admit that its capabilities are limited. In cases of excessive over-exposure it is at best but an unsatisfactory remedy, and in the majority it will be found no remedy at all. As it is, however, generally possible to avoid giving an exposure greatly in excess of what is required, and seeing that in practice such an exposure is comparatively rarely given, this drawback to the employment of the bromide restrainer does not make itself greatly felt.

Over-exposure, in fact, is seldom intentional, and therefore, when it does occur, the probabilities are that it will be slight rather than excessive.

To those who are content to work under these limitations, the ordinary treatment is probably the best that could be devised to meet the difficulties of the case. There are, however, many who, at some sacrifice to the established order of things, would welcome a method of treatment under which greater latitude of exposure might at all times be obtained.

I am glad to see that Mr. Debenham seems to be of this way of thinking. He appears to recognise what is, in fact, the very gist of the matter, to wit, that excessive exposure must be regarded as an evil only in proportion to the extent to which it defies remedy.

That it does frequently defy remedy under the old treatment is only too evident, otherwise it would not be looked upon, as it still is, as one of the chief bugbears of practical photography. The very fact that we photographers, as a body, have not attempted to formulate a scheme of vastly increased exposures is tantamount to a confession of our inability to deal with the difficulties that would arise during development were such a scheme actually adopted. Yet, provided we are willing to exchange the existing form of restrainer for one more energetic and effective, I fail to see that there is any reason whatever why we should not avail ourselves of the advantages presented by a scheme of this character.

In January 1894 I described in these pages a simple method of controlling the development in cases of over-exposure. As some of my readers may perhaps remember, I proposed to convert the excess of reduced bromide of silver in an over-exposed film into chloride of silver, the latter salt, as most photographers are aware, being little, if at all, affected by the action of the developer. In order to effect this conversion, I employed a weak aqueous solution of chlorine gas. After a preliminary soaking in this solution (the duration of which, of course, varied according to the length of the exposure), the film was removed, rinsed, and developed in the ordinary way.

Looked at from a purely theoretical standpoint, this process seems admirably adapted to effect the purpose for which it was designed. Nor, indeed (as I endeavoured to show in the paper already referred to), is its practical value to be under-rated, seeing that the remedy can, after a few trials, be applied in such a way as to produce really excellent results. It is not, however, a remedy that is likely to become popular, at all events so far as the average photographer is concerned. In the first place, he will probably be unwilling to be at the pains of preparing a chlorine solution. This, however, is not the only difficulty he will have to encounter. Having prepared the solution, he must next experiment in order to ascertain its strength.

What is worst of all, he will have to repeat the testing operations from time to time, owing to the unfortunate circumstance that the gaseous solution cannot be preserved without there ensuing a gradual loss of strength.

Obviously, then, this form of treatment, though sound in principle, will not be viewed with favour by those whose demand is for a simple practical remedy for over-exposure.

Fortunately, there are several other reagents which are capable of supplying the place of the chlorine water in the process above described, and by the application of which the conversion of the reduced bromide into chloride may be quite as readily effected. There are, for instance, the perchlorides of certain of the commoner metals.

Of these, the most suitable for photographic purposes are those of iron, copper, and tin. At present I intend to confine my remarks to ferric chloride.

A solution of this salt, as I need hardly remind my readers, is sometimes employed as a reducing agent. On immersing an over-dense negative in such a solution, the metallic silver of which the image is composed is gradually converted into chloride at the expense of part of the chlorine of the iron salt, the latter being thereby reduced to the ferrous state. These changes are represented in this equation:—

$$Fe_2Cl_6 + 2Ag = 2AgCl + 2FeCl_2.$$

We might here substitute cupric chloride for the perchloride of iron, in which case the products of the double decomposition would be argentic chloride and cuprous chloride, and the following equation would then represent the reaction:—

$$2CuCl_2 + 2Ag = 2AgCl + Cu_2Cl_2.$$

Suppose, however, that, instead of treating the visible image which has been produced by the action of the developer, we apply one or other of these solutions to the exposed film immediately before development. Should we do so, we shall find that, though the chemical reaction remains substantially the same, the results are somewhat different. Let us consider the two cases apart. In the first, we apply the treatment after the development, and thereby effect a certain reduction in the absolute or apparent density of the visible image. In the other case, the only difference is that the film has been treated with the chloride solution *before* development. Here, reasoning by analogy, we shall probably be led to conclude that we have effected a reduction in what, for want of a better term, I may call *the potential density of the latent image*, such, as experiment proves, is, in fact, the case.

Now, under ordinary circumstances, we go to work to reduce this potential density in quite another way, that is to say, we add a restrainer to the developer, and, by means of the former, control the growth of the absolute or apparent density. It is evident, therefore, that, in cases of over-exposure, the one form of treatment may be substituted for the other. The chloride treatment is, however, to be preferred whenever we are dealing with excessive exposures, seeing that the ferric salt, as compared with the bromides of the alkalies, is by far the more powerful in action. In practice I have obtained the best results with a solution of the strength here given:—

Hydrated ferric chloride	30 grains.
Water	10 fluid ounces.

Just a word as to the hydrated ferric chloride. This salt, being extremely deliquescent, cannot be preserved in the crystalline state for any considerable length of time. A ten per cent. stock solution should therefore be prepared in the first instance, a portion of which is to be diluted to the proper extent when the solution is required for use.

MATTHEW WILSON.

(To be continued.)

ON A NEW METHOD OF PREPARING PLATES SENSITIVE TO THE ULTRA-VIOLET RAYS.*

III.—Increasing the Sensitiveness of Silver Bromide to the Ultra-violet Rays.

The sensitiveness of silver bromide to the rays beyond wave-length 220$\mu\mu$ may be increased by the addition of silver iodide. In the same way as gelatine emulsion plates with bromide of silver are improved by iodide, so may also be the plates sensitive to ultra-violet. Plates have been tried containing 5, 10, and 20 per cent. of silver iodide, and better results have throughout been obtained than with pure silver bromide.

* Continued from page 220.

The iodide increases not only the sensitiveness but also the intensity and clearness. *This only obtains, however, when both the bromide and the iodide are precipitated together from the same solution.* A mixture of the two precipitated apart from one another givee plates of very ordinary sensitiveness. Pure silver bromo-iodide is consequently also very variably sensitive to the rays beyond 220$\mu\mu$, according to the manner of its preparation, as bromo-iodide emulsions with gelatine are with respect to the rest of the spectrum.*

I give below the formula for preparing bromo-iodised plates sensitive to ultra-violet which have answered better than all others for my photographs of the shortest wave-lengths:—

A.

Potassium bromide	6 grammes.
Potassium iodide	0·6 ,,
Emulsion gelatine	1 ,,
Distilled water	100 c. c.

B.

Silver nitrate	8·1 grammes.
Distilled water	100 c. c.

After melting the swollen gelatine, both solutions being heated to 50° or 60° C., B is poured in very small quantities into A in the dark room, being well and often stirred meanwhile, set in boiling water for half an hour and also well stirred, then allowed to cool to 40° C., 4 c.c. ammonia added and again well stirred up, allowed to cool further for half an hour or warmed in a water bath not oves 40°C. After that 64 c. c. of the fluid is poured up 4 litres of warm water not over 40 C., well stirred, filtered, and after standing for one to two hours, the silver iodo-bromide is left to settle as described before. After drying, the plates must be washed for a time in standing or quietly flowing water, which at first is frequently changed.

IV.—The Settling of the Silver Bromide.

Glass developing trays with flat bottoms made of moulded glass are suitable for settling the silver bromide. The inside dimensions of the bottom should be at least $\frac{3}{4}$ of an inch larger than the plate. After a good cleaning with sulphuric acid, the dish is filled to about three-fourths its depth with the filtered bromide solution, and the plate, dusted on both sides with a soft brush, is laid down so that it is at least $\frac{3}{4}$ of an inch from the farthest edge. The time required for settling varies according to the preparation of the silver bromide. As soon as the edges of the plate can be seen through the fluid it is time to empty the dish and dry the plate. The dish is inclined forward and the fluid runs off with a syphon reaching to the bottom of the dish in front of the plate. The remaining solution is soaked up carefully with blotting-paper from one corner so as not to damage the surface of the plate. The plate can then be taken out of the dish. Care must be taken not to touch the film with the fingers. If the film contains gelatine, it will contract for some distance round the finger mark and probably damage the coating. The plates should be taken out of the dish by the edge and held by the lower side, and, besides, be kept as horizontal as possible. Then they are laid to dry in a place free from dust, but in a drying box as for gelatine emulsion plates. A few hours are sufficient. The plates dry more quickly standing, only the film is easily split by so doing and shifts away in places; or the heavier particles may move downwards and cause furrows which will develop as transparent lines with denser edges.

The Dry Plates.

(*a*) *Before Exposure.*—In drying, the sensitive coating of the plates will be distinctly more transparent for the optically light rays, especially if the silver bromide contains gelatine. I have had plates which while wet were only translucent, but after drying were completely transparent to my dark-room light (stearine candle light filtered through three thicknesses of brown tissue paper).

After drying, silver bromide containing gelatine adheres very strongly to the plate, pure silver bromide on a gelatine coating is not so good, especially with a thick coating, and on a plain glass surface makes such a loose deposit, that its employment for photographic negatives is attended with great difficulties. However, when once they are dry, these plates can be set up standing in water to remove the potash salts in the coating, which is as necessary in this as in the other preparations.

The coating is very sensitive to mechanical pressure. It will even

* I have obtained better results with plates containing about 10 parts of silver iodide to 100 parts of silver bromide, than with any other plates. For photographing the most refragible rays of the new spectral region I have only used bromo-iodide plates. It should, however, be mentioned that a year elapsed between the preparation and the exposure, during which time the specially high sensitiveness may have been acquired by an after ripening.

scarcely bear dusting with a brush without injury. To direct pressure it is generally less sensitive. When cutting with a diamond, the rule may be laid direct on the sensitive side without fear of injury to the film. Under still stronger pressure many sensitive coatings change their properties. I come to this conclusion from the fact that plate numbers stamped on with a soft rubber stamp always develop intensely black, whereas the same way of marking in all other cases gives the numbers as clear as glass.

The colour of the coating of the plates is, with silver bromide, white, with a trace of yellow; with mixture of silver bromide 100 and silver iodide 5, somewhat yellower; with the bromide and iodide in the same proportions, precipitated together from the same solution, citron yellow, and, with 10 parts of iodide, light orange yellow.

Pure silver haloid gives a dull coating; with gelatine it is more glossy. By the light of the dark room it generally appears faultless, except at the edges, which show uneven streaks. By daylight, however, it is different, and fogginess and unevenness of the deposit may often be noticed. On development these appear as dense spots unless certain precautions are very carefully observed. Moreover, the film always contains some particles of dust, however carefully the plates may be prepared, and under the microscope these spoil the image, and sometimes render it useless. Fortunately this only happens when the image of a line taken with a very fine and short slit opening falls upon impurities, and so becomes uncertain.

(*b*) *The Photo-Chemical Colouring.*—My observations will here be confined to films containing gelatine, and even with these only to a few tried in direct sunlight. In presence of sunlight, the sensitive films are affected differently according to their composition.

Silver bromide is coloured at first greenish blue, and becomes grey blue without gaining greater intensity. If only part of the plate is exposed, this appears surrounded by a greenish-blue aureola, the result of total reflection, by which the rays are thrown off from the back of the plate, A mixture of iodide and bromide darkens much more strongly than pure silver bromide. It becomes grey blue and shows only a trifling halo. The iodide and bromide precipitated together takes a still more intense grey blue colour and shows almost now aureola.

(*c*) *The Photographic Colouring.*—The colour acquired in development by plates sensitive to the ultra-violet is, as is universal in photography, quite different to the photo-chemical colouring. For development only pyro and soda are used. With normal exposure, the film of silver bromide is coloured grey black, while that of the bromo-iodide is blackish-brown. However, by suitable dilution of the developer, both may be made darker and more intense. Of this more anon.

If a full exposure is given, the image sometimes appears light brown and is bordered with dark brown. If the exposure is still further increased, solarisation take place. The exposed parts appeared transparent, almost like clear glass, in the middle of an extensive halo; for this I have burnt 25 cm. of magnesium ribbon, one to two centimetres in front of a plate, covered with a perforated screen. If the plate is prepared with silver iodide and bromide precipitated together, there is no solarisation (I have used plates containing 5, 10, and 20 parts of Ag. I to 100 parts of Ag. Br.). The exposed surface is then strongly blackened, and stands out strongly from its wide transparent surroundings. This was also the case with prolonged exposures. All these experiments were made with plates containing gelatine. I have also tried silver bromide plates containing agar-agar, but found that they solarised even more readily than the gelatine plates.

VICTOR SCHUMANN.

COLOUR IN NEGATIVES.

THE great recommendation of our more modern developing agents is generally held to lie in the immunity from yellow colour or stain attained by their use. I think it is pretty well admitted on all sides that pyro-gallol will do very nearly all that amidol, metol, rodinal, *et hoc genus omne*, can accomplish. Our old friend, though, arrives at his results by a somewhat different method. For instance, if we wish to get all possible detail out of a plate suspected of under-exposure, we naturally keep the pyro very low, so that the high lights may not acquire undue density. This involves protracted development, and, as a natural sequence, a considerable amount of yellow stain in the negative. Supposing the same plate were to be developed by the agency of metol, there would be no occasion for the dilution of the developer; rather should we strengthen it, because a concentrated, unrestrained metol developer will flash up all detail at once, and only take on density very gradually, enabling us to stop development at the right moment.

If two such negatives are compared, there will be a great difference, visually. The metol-developed plate will be of an even grey colour in the greater deposits of the high lights that will make it very acceptable to the eye, especially when the total absence of deposit or stain in the deepest shadows is taken into account as well. Altogether, it will present a great and pleasing contrast to the pyro-developed plate. This latter will, on comparison, have an almost objectionable appearance, entirely arising from the difference in the colour of two deposits and the stain over the whole surface of the gelatine.

But negatives are not made to look at; they are simply a means to an end; they are an unfortunate necessity on our way to produce finished prints. Therefore, the two negatives shall fulfil their mission, and shall yield us prints—for simplicity's sake, silver prints. The pretty-looking grey negative will soon be printed deep enough for toning; but we shall have to wait for the yellow one. When it is done, we may proceed to finish them in then usual way; but already, before they are put into the first washing water, there is a very noticeable difference, and the boot is on the other leg now. The prettier-looking negative (as far as colour is concerned) does not give the better-coloured print of the two; quite the reverse, in fact; and, when toned, the difference is still more pronounced, because the slower-printing negative gives a print that takes on an entirely different range of tones to the other one. The experiment will probably end with a decision on your part that there is still a deal to be said in favour of pyro as a developer.

I do not say that this little experiment is theoretically and scientifically correct. It can be argued, with a good show of reason, that the personal equation had not been eliminated; that, for comparative purposes, the two negatives should have been developed in such a manner that the opacity of the highest lights was similar in each one *by measurement*, and not by judgment; and that the metol-developed plate was, in reality, under-developed. Exactly so; but theory is not practice. In the dark room, when developing our beloved snap-shots or less lovable, but more remunerative, studio exposures, the personal equation is the all-important factor. We cannot use an apparatus for measuring densities during ordinary development, we are obliged to use our eyes; and, finally, most metol-developed negatives *are* under-developed by reason of these things.

But, given two negatives which shall be measured and proved of equal opacity in the highest lights, and with equal range of gradation throughout—one of which shall have the familiar pyro stain and the other be totally free from it—I have yet to be convinced they will yield prints identical in colour, richness, and quality.

Now, after all this, you will be somewhat surprised, perhaps, to hear that I use metol frequently, but I put it *into* the pyro developer, where its good qualities are utilised without the drawbacks mentioned.

There is moderation in all things (there should be, at least); certainly it is so in the amount of yellow stain permissible or advantageous in a negative. For this reason I never had a great affection for pyro ammonia. I do not care for a negative that takes a week to print in winter and a good hour or hour and a half in brilliant summer sunlight. True, the use of sulphites will control it, but, just when the action of sulphites in the developer was beginning to be generally understood, I took a great liking to the use of carbonates as accelerators. I have never lost that liking, and have only used ammonia when really driven to it.

It is more particularly to the power that exists of moderating and controlling the amount of colour in a negative developed by pyro soda or pyro potash that I wish to call attention. I will presume that a developer is in use composed as follows:—

Pyrogallol		2 grains.
Potassium bromide		½ grain.
Soda carbonate		14 grains.
Soda sulphite		9 ,,
Water	up to	1 ounce.

Modifications of this developer will act in a similar way, but it will simplify matters if I name a standard and explain its actions. The modifications referred to may be the addition of further bromide or the omission of it entirely; the addition of metol or amidol, as taste may suggest, or the substitution of an equivalent quantity of potassium carbonate in place of soda carbonate. I may also say that, although I have not tested the reactions subsequently mentioned in the case of pyro ammonia (plus sulphite) developer, I believe they would be much the same.

And now a word or two about compounding the above developer. I entirely agree with the *dictum* laid down by the Britannia Works Company as to the function of a sulphite in the developer. It should *not* be used as a pyro preservative, but is simply present in the developer for the

purpose of controlling the amount of colour that shall be present in the finished negative. Therefore, in practice, I make up two solutions, one containing pyro and bromide, the other carbonate and sulphite. As to preservative, a few drops of nitric or sulphurous acid may be included in the pyro stock solution if necessary, but this is not often in my case. I find that, if an ounce of pyro be dissolved in forty ounces of water, it will not keep above a couple of days; but, if you dissolve half an ounce of potassium bromide in the water first, and then add the pyro, it has much greater keeping qualities. It is always fit for use at the end of a fortnight, and I have used it three weeks old without finding any noticeable loss of energy. The solution certainly acquires a slight brown tint, but it does not become muddy, as a plain pyro solution does. (I do not remember having seen or heard any reference in the photographic press to this preservative property of the soluble bromide, but it is a fact, nevertheless.) So you see it will depend on the amount of developing you are likely to get through. If you are so constantly at it that an ounce of pyro will not last you much more than ten days, the acid is not necessary; if you only do a little developing now and then, it will have to be used; but omit it if you can, as it has a slight restraining action.

News and Notes.

ROYAL PHOTOGRAPHIC SOCIETY.—Ordinary Meeting, Tuesday, April 14, at eight p.m., at 12, Hanover-square.

WE congratulate our friend, Mr. F. A. Bridge, who, on April 2, was married to Miss E. M. P. Harding, a lady well known and respected in the photographic world. She has been engaged in the practice of photography for some years, and formerly belonged to the old South London Society. We wish Mr. and Mrs. Bridge every happiness and success.

MR. J. A. C. BRANFILL writes: "I notice that, in your article on *The Use of the Swing Back in Enlarging* on the 20th ult., you say there exists no ready means for calculating the position of the negative in order to secure at once perpendicularity and sharpness. I think you will find the formulæ I gave you (see page 703 of your last volume) will provide a ready means for that purpose as well as for determining the position of enlargement."

A PHOTOGRAPHIC CLUB FOR DUNFERMLINE.—A meeting of those interested in photography was held in No. 1 Committee-room, St. Margaret's Hall, on Thursday, April 2, Mr. J. W. Robertson presiding, for the purpose of forming a photographic club for Dunfermline. The proposal was unanimously approved of, and Mr. William Hutton, Teller, Bank of Scotland, was appointed Secretary and Treasurer of the new Club, which it is thought will, ere long, have a membership of between forty and fifty.

MR. C. C. VEVERS, of Leeds, writes: "I shall be obliged if you will notify my change of address after April 1 to 163, Briggate (a few doors below Duncan-street), which I have had entirely refitted and lighted with electricity. My second-hand showrooms and printing and enlarging department are also on the premises. I have taken workshops, with provision for forty or fifty benches, in Lambert's-yard, behind shop, and Proctor's-yard, Call-lane, which I shall shortly have in full working order. Customers whose orders have been delayed during removal, please accept apologies and asaurance that they shall now have immediate attention."

A BOOK FOR PAINTERS.—We are informed that Mr. Hector Maclean has now in the press a handbook, entitled *Photography for Artists*, which, adorned by many illustrations contributed by artists and photographers, will probably be not only a usetul guide to all who lean upon photography for illustratiou, decorative design, or picture painting, bnt also a work which will contain much to please the eye. Especially interesting are Mr. Linley Sambourne's photographs, and the line work tounded thereon. Amongst the several distinguished photographers whose prints are reproduced are Dr. P. H. Emerson and the late Colonel Stuart-Wortley.

PHOTOGRAPHIC INFLUENCE UPON PAINTING.—The reform and improvement brought about by the camera as regards truthfulness of rendition in the various walks of pictorial art have not of late been more emphatically illustrated than by the numerous scenes—numbering almost four hundred—by means of which M. Tirrot depicts the history of Christ. These are now on view at the Lemercier Gallery, 35, New Bond-street, and are well worthy a visit, not only on account of the consistent and vivid manner in which they tell the story of the Redemption, but because they typify the still-growing demand for complete actuality. This M. Tissot appears to have been able to supply, by means of a ten-years sojourn in Palestine. Other painters often find that they can satisfy the popular craving for realism by the more convenient method of working from photographs.

TO PREPARE A TRANSPARENT MIRROR.—The following process for producing a mirror which reflects from one side, but is transparent from the other, has been patented in Germany:—Dissolve 1 part by weight of silver nitrate in 10 parts by weight of water, and label No. 1. Prepare another 10 per cent. solution of silver nitrate, but in larger quantity. To this add ammonia water, drop by drop, stirring carefully until the precipitate formed at first is completely dissolved, and label No. 2. Now add solution No. 1 to solution No. 2 until the odour of ammonia is no longer recognisable, and the liquid has again become very turbid. Now add 100 parts by weight of distilled water for every part of silver nitrate originally used in solution No. 2, and filter until clear. Label this No. 3. Prepare a reducing solution by dissolving 0·8 part by weight of Rochelle salt in 384 parts by weight of distilled water, boil, and to the boiling solution add gradually a solution of 3 parts of silver nitrate in 10 parts by weight of distilled water, and filter when cool, and label No. 4. Clean the glass to be coated thoroughly, lay it on a perfectly level surface in a room at a temperature of abont 25° C. (77° Fahr.). Mix equal parts of No. 3 (the depositing fluid) and No. 4 (the reducing fluid), and pour over the glass. The glass may, if preferred, be dipped into the solution. The time required for the deposition of the layer of silver of just the correct thickness has to be determined by the judgment of the operator in each case, and this may be aided somewhat by observing a piece of white paper below the plate of glass. When a sufficient deposit of silver has been made—and much less is required than for an ordinary mirror—pour off the silvering liquid, and rinse thoroughly with the distilled water, and stand the mirror on edge to dry; coat the silvered side with a solution of colourless shellac in alcohol, and finally frame the mirror with a backing of clear glass to protect the mirror surface from being scratched.

PHOTOGRAPHIC CLUB.

APRIL 1,—Mr. S. H. Fry in the chair.

Mr. HORACE WILLMER said that the widow of the late Mr. Bedford had informed him that she proposed to have an enlarged photograph of her late husband made, and she would offer a copy to the Club as a memorial of him.

The CHAIRMAN, in suitable terms, expressed the pleasure that he knew the members of the Club would feel in having a picture of their old friend placed in the Club-room.

Mr. GOTZ brought forwsrd a proposition that there should be a summer outing of the membera and friends of the Club, to take place somewhere about midsummer. He said that the outings of the Club, which were at one time a great feature of its life, had fallen somewhat into desuetude. He thought that a small committee, having the projected scheme at heart, could arrange for a whole day's outing, and that suitable arrangements for a meal in the evening could be included.

After some discussion as to whether the outing should take place upon a Bank Holiday or a Saturday, it was arranged that a whole day's outing of the Club should be held at or about midsummer. Arrangements wonld be made so that those who chose, or who could only spare half a day, could join the excursion. It was left to Mr. Gotz to bring the matter forward againlat an early date, when a committee could be appointed, and the final arrangements made.

In the absence of Mr. Wall, the paper of the evening fell through, but the question of the infinence of

THE COLOUR OF A NEGATIVE UPON ITS PRINTING QUALITIES

was formally discussed.

Mr. JAMES CADETT, who opened the discussion, described, with blackboard illustrations, some of the principles upon which density measurements are made, and discussed the way in which the colour of the deposit affected these measurements. He said that the question of the colour of the negative as regards its speed wss not an unimportant one, because it was often the case that the visual density of the negative was by no means an index of its printing density; in other words, the negative may appear very dense, and yet not be a good printer. He pointed out that the difference in colour of deposit of a

negative might appreciably alter the number of steps of gradation, while it would not affect that portion of the Hurter & Driffield curve which is known as the period of correct exposure, and so, in reading the speed by the graphic method, the straight-line portion of the curve would cut the base of the diagram at the same place, and the speeds would read alike. After dealing with the inertia of a plate, and explaining that, whilst the exposures increase in geometrical progression, the density deposit augments in arithmetical, he went on to say that, after considering the matter in its practical bearings, he considered the question of colour or stain was not a momentous one. It was possible there was a stain image, and also a silver image. If there were any advantage at all, it was in favour of an image with a certain amount of stain. He thought that, as far as portrait negatives were concerned, it was necessary that they should not be stained, but that they should be made in a colour as nearly as possible representing the pencil which was used for retouching.

Mr. A. COWAN agreed generally with what the previous speaker had said. He thought that the stain did go equally through the negative, although it might be more apparent in the shadows than elsewhere. Perhaps it was covered up by the heavy deposit in the higher lights. He instanced the case of green fog, which was only visually obtrusive in the under-exposed or shadow portion of the plate. Notwithstanding this, he thought the green fog did go right through the plate, but that it was less noticeable in those portions where there was more deposit.

Mr. FRY said that it was perhaps unfortunate for the Hurter & Driffield method, of the main principles of which he was entirely convinced, that certain statements had been attributed to the authors—whether rightly or wrongly—which did not affect the question and which statements were known to be, if not incorrect, at least exaggerated. He also took the occasion to deplore Mr. Cadett's own action in using the double series of speed numbers. He thought it most unfortunate that what was after all only an arbitrary standard for each maker's own plates should be confused by the addition of an extra set of numbers which could serve no useful purpose whatever. The value of the numbers consisted in the fact that, if one box of plates was marked 100 and another 200, the latter might be assumed to be twice the speed of the former, and no advantage that he could see was gained by doubling the numbers, but some confusion might well arise.

Mr. HODD agreed with Mr. Fry, and put his objections into a concrete form.

In reply, Mr. Cadett said that users of his plates had complained that they were under-speeded when he had used the standard ferrous-oxalate developer for arriving at the Hurter & Driffield number. He went on to say that, with recent samples of pyro, he had found the speed of plates to be three times as fast as with the Hurter & Driffield standard development, and he suspected that makers of this developer might be mixing it with one of the newer developers, such as metol, or in some way varying it. In any case, he noted the fact that, with some makers, or, rather, with some batches of pyrogallic acid, he got higher speed results than with others.

Mr. FRY said that he thought this entirely supported his argument that the second speed number was a mistake, as the only logical course for Mr. Cadett to adopt now would be to add a third set of speed numbers for the more rapid pyrogallic acid. This would tend to reduce the whole system to an absurdity. It was an interesting fact, however, to hear it stated on authority that one sample of pyrogallic acid worked faster than another.

Mr. COWAN said that the Committee of the Royal Photographic Society, which had dealt with the question of speed determination, was thoroughly agreed upon one thing, viz., that the only correct method of speed determination was that one which tested the particular plates with the particular developer with which they were to be used.

Mr. CADETT said that Hurter & Driffield were undoubtedly wrong when they said that all developers gave equal speed.

Brixton and Clapham Camera Club.—March 24.—Mr. R. C. WHITING, of the Ealing Photographic Society, spoke on the

IMPROVEMENT OF LANDSCAPE NEGATIVES,

having, on a previous occasion (February 25), dealt with the retouching of portrait negatives. At both meetings a good attendance was present to benefit by his instruction. In his introduction Mr. Whiting said most portrait negatives underwent retouching. The necessity for this can be understood when we consider the inadequate sensitiveness of the ordinary plate to such colours as red, green, and yellow, and its over-sensitiveness to blue and violet, although this difficulty is partly got over by using orthochromatic plates. Again, the camera has a tendency to exaggerate and accentuate lines and wrinkles such as are caused by age, &c., and to remove this exaggerated effect is the retoucher's work. Difficulties are also met with in lighting the subject and in development, and here once more the negatives are susceptible to after-improvement. It may be objected that this is not photography, and where an unlimited amount of work is put upon a negative, sometimes to such an extent as to destroy any characteristic likeness it may have possessed, there is good reason for this objection, but to legitimate retouching for the removal of blemishes there can be none. The great thing is not to attempt too much; to do too little is far better. Many retouching desks are faulty; they have mostly a want of size and stability, and have too much incline, which is tiring to the hand. The desk should be placed at such a height as will avoid stooping on the part of the operator, a practice which is not conducive to good work. The elbow must be placed on the table, the hand allowed free play, and care taken to place no weight on the pencil. All light, except that passing through the negative, should be cut off, and, in place of the ground glass usually placed behind the desk for a reflector, a piece of deeply flashed opal may, with advantage, be substituted, as this better shows the effect of the lead in relation to its printing value. The hand ought to be kept from the negative, as a better command over the pencil and more power of manipulation is obtained, and the negative should be lowered or raised, and placed at any required angle. The brush and colour and black chalk are useful for large work where a bold touch is wanted. The work requires fixing with isinglass, squirted from a scent spray, or with indiarubber solution. The pencil will, however, be more generally useful, those of B. S. Cohen being especially good. HB and HH will be found about right for average work. For retouching the face, the pencil is sharpened to a long, thin, needlelike point, a shorter point being used where a bold, heavy touch is wanted. A medium can be done without if the negative is coated with a soft varnish, allowed to dry, and then rubbed with the finger until rough, but the negative often won't take sufficient lead by this method. When a medium is used, don't rub in with the finger, but place a few drops on a handkerchief and allow to dry, then add a few drops more on the rag, and, placing the finger over, rub with a circular motion on the negative until the rag sticks and is difficult to move. If worked too much, the medium won't take the lead; if too little, it takes it too thickly, and in dots. Mr. Whiting next showed how retouching is carried out in practice, how and where the lead should be applied to produce the required grain and light-and-shade effect, how high lights could be scraped down with a sharp knife, Indian ink and Payne's grey used to fill in scratches in the film, &c. He also emphasised the necessity of a knowledge of anatomy and drawing to any one undertaking retouching. For retouching landscape negatives, a knowledge of the laws of art is essential to success. The most suitable process for a particular negative should first be chosen, then a print taken in that process, the same as that in which the finished picture will be produced. The principal point in landscape work is the proper light and shade balance. As a rule, the centre is the weakest part of the picture, and on no account should the strongest light come in that position. The print can usually be trimmed to avoid this, then the negative is retouched so as to strengthen the lines where advisable, or subdued so as not to over-assert themselves. As a rule, the sky also wants treatment. Even if clouds are present in the negative, they are mostly in a wrong position, and it is better to mask them out and print in clouds from a separate negative, or else to manufacture artificial clouds, which can be done by varnishing the negative with white hard varnish, thinned with turps, allowing five or six hours to thoroughly dry, then rubbing the finger (dipped in powdered resin if handy) over the surface of the negative until it looks like ground glass, rubbing off the powder with a little cotton-wool. Clouds can then be placed in with a stump dipped in electrotyping plumbago, and the print rubbed on a bit of washleather. Clouds may also be put on the back of the negative, but are generally objectionable, inasmuch as they print with no definite outline, but with a woolly appearance, unlike any natural cloud form. A very non-actinic colouring for the back of the negative consists of putty mixed with yellow ochre and chrome yellow. This is dabbed on where required. Matt varnish can also be used, and should not be scraped away except where there are dark shadows (as the trunk of a tree). It is occasionally useful to cover the back of the negative all over with matt varnish, and work on it with the cravon, stump, but better results can generally be got by working on the film. Mr. Whiting was listened to very attentively, and replied to numerous questions, also suggesting how various prints handed to him could be improved. Asked whether it is possible for an amateur to successfully retouch his own negatives, he said yes, as the ability to make good photographs would also enable him to exercise the required judgment and tasts in remedying their defects. Mr. Thomas, in proposing a vote of thanks to Mr. Whiting, testified to the great pleasure he had received from his address, and cautioned the inexperienced against attempting too much. The beginner should learn how to obtain such a control over his materials as to render little retouching necessary, there was nothing equal to "good old nature," after all, and in printing in clouds he considered far better results were generally obtained by using a real cloud negative than by working on the film. The subscription list opened in aid of Mr. W. H. Harrison was referred to. Mr. Harrison is a member and past Vice-President of the Society, and many members have pleasureable recollections of the great interest he has always taken in it, of his readiness to assist in filling up the programme, and of the many valuable papers he has read to the Club, papers which must have cost him an inconceivable amount of labour. It is certain that many members will desire to contribute to his assistance now the necessity for it has arisen, and any sums sent to the Secretary for this purpose will be very welcome.

Croydon Camera Club.—April 1, the President (Mr. Hector Maclean) in the chair.—The subject was

HOW TO MAKE A GOOD NEGATIVE,

being the second of this season's Novices' Nights. The matter was opened by a short address from the PRESIDENT, in the course of which he urged on amateurs that the well-worn advice, to "choose a plate and stick to it," should be discarded. Where, as with the ordinary amateur, the camera is turned upon all kinds and conditions of subjects, it is absolutely needful that one should be able to intelligently handle various makes of plates; to know what one particular brand will do, and how it needs humouring, is insufficient, the knowledge must be extended to a familiarity with several leading types, such as extra-rapid, slow, extra-slow (photo-mechanical), isochromatic, and anti-halation. Moreover, the amateurs should know why and when a thickly-coated plate is preferred over a thinly coated one, and *vice versâ;* he should also be aware that the two require some difference of treatment as regards development. Many of these points were touched on, which cannot be here reported. Messrs. S. H. Wratten, A. E. Isaac, W. H. Rogers, J. Smith, and others took part in the discussion; after which Mr. JENKINS gave a practical demonstration for the benefit of such novices as were present. Messrs. H. T. Marey, H. Davies, and J. C. Taylor were elected members.

Richmond Camera Club.—At the meeting on the 30th ult., Mr. Purcell presided, and a very full and interesting demonstration of

THE PLATINOTYPE PROCESS

was given by Mr. STRINGER, of the Platinotype Co. At a meeting on the 1st inst. it was decided to form a cycling section in connexion with the Club, with a general view to cycling and photography combined, and a provisional committee was appointed with Mr. Gibson as Captain, and Mr. Richards as Vice-Captain and Secretary.

Woolwich Photographic Society.—March 26, Colonel C. D. Davies pre

siding.—Mr. J. C. S. MUMMERY (President of the North Middlesex Society) gave a paper on

MOUNTING AND FRAMING.

He commenced by giving hints on suitable mountants and their preparation, his favourite being freshly made starch. This should be allowed to cool, with a cover over it to prevent the formation of a hard skin on top, which generally broke into little lumps when being applied to prints. A little cold water poured on the top effectually excludes air, and makes a good cover. Passing on to mounts, he said that white card, as a rule, was too strong and bare for ordinary prints; but, if one or more lines were ruled round print, after mounting, with lead pencil, this bareness was overcome. Sometimes the desired effect can be obtained by using an extra thickness of glass. This was illustrated by a print, one portion of which was uncovered, and other portions with one and two thicknesses of glass respectively. In cut-out mounts there should be no fancy curves or ornament, or the eye is taken away from picture to decoration on mount. In large subjects and bold effects strong contrasts are allowable, but in ordinary subjects harmony is necessary. The general effect of a mass of colour is emphasised by placing against the complementary colour and *vice versâ*. Mr. Mummery here showed the effect of an orange-red mount and a grey mount, the red mount sharpening up the print, and the grey softening and accelerating the atmospheric effect. To increase appearance of gloss, use rough mount, and, for increase of matt appearance, use glossy mount. Do not write titles in ink, and very best writing in conspicuous place, but use pencil in unobtrusive corner. Two to three is generally considered best proportion for cutting mounts, but each print must be considered and tested by itself. Increase of width of mount and frame gives square appearance to picture; width of mount showing must not equal width of picture. For frames, broad and simple moulding is the best. The frames and mounts should be rectangular; any variation of this at once attracts attention to the frame, and takes the eye from the picture. Originally no frames were used for pictures; they were painted on walls, &c. It should be well considered where the picture is to be hung—at an Exhibition, or on a fancy wall paper. If for exhibition, it may fairly take its chance, but the colours of wall paper must be taken into account. When finished, the picture should arrest and give satisfaction to the eye; it should appear complete, and not give the idea of being abruptly stopped or cut off, and the eye should be entirely unconscious of mount or frame.

Bath Photographic Society.—March 25, Mr. George F. Powell (President) in the chair.—Mr. GEORGE NORMAN gave his promised lecture, entitled

A TRIP TO THE BALTIC.

He said the portion of his trip from Bath to Scandinavia need not be dwelt upon, but he would commence with the landing at Christiania. Views of the harbour were shown, then the important features of the place were described in detail, the customs of the people, their industries, simple habits of life, religious observances, pleasures, educational work, and domestic architecture, &c. Passing on to Stockholm, the lecturer similarly treated his subject, the whole of his remarks being copiously illustrated with lantern slides from photographs he took as opportunities occurred. Several views of Cronstadt, with its practically impregnable fortresses, and many Russian ironclads were shown, and interesting details concerning them given; but here, said the lecturer, photographing was strictly forbidden. St. Petersburg was next in order, and upon the magnificence of this great capital, its fine churches with immense pillars of granite and gilded towers, gorgeous palaces, shrines, theatres, and fine streets, the audience was well entertained with information the lecturer had been able in his brief stay to collect. Journeying to Moscow, a still greater wealth of splendour was presented; but the illustrations here, as also at St. Petersburg, were of Russian production, owing to the stringent police regulations in respect to touring photographers. Upwards of eighty pictures in all were displayed on the screen during the delivery of the lecture, which occupied nearly two hours.

Leeds Photographic Society.—In consequence of the Ordinary Meeting falling due on the day before Good Friday, it was resolved it should be held in the Society's rooms on Monday, March 30, instead of April 2. Some of the most prominent manufacturers of photographic apparatus having sent down their latest productions for exhibition and criticism, the meeting was opened with a display of their goods an hour earlier than usual. Special approval was shown of time and instantaneous, snap-shot, studio (a beautiful arrangement for silently obtaining children's pictures), and focal plane shutters, the patented articles of the Thornton-Pickard Manufacturing Company; also their new automatic tripod. The metal dark slide and dark-slide adapter (Edwards's patent), as well as sundry devices for carrying, exposing, and developing films met with a good share of appreciation. Amongst other articles worthy of mention were a bromide lamp (Groom's patent), a model of an improved sectional print-washer, specially designed to keep prints or negative films from contact with each other during their cleansing from chemicals which would affect their permanency. The "Zoppo" shutter commended itself to the admiration of the members for its ready means of adaptation to different-sized hoods, and the silent working of the shutter (a clever one of the ever-set type). One little novelty would have commended itself to the lady members, who, however, were conspicuous by their absence on this occasion, the later business of revision of rules, it being suggested, having something to do with their non-appearance. We refer to the rubber sensitive finger covers. Over half an hour was spent in amending the rules of the Society, copies of which will be forwarded to the absent members in due course. The event of the evening, however, was Mr. J. H. WALKER'S (ex-President) lecture on the

PHOTOGRAPHIC CONVENTION AT SHREWSBURY, 1895.

In his opening remarks the lecturer said the great idea of the age was centralisation. In business, in trusts (mining and otherwise), they found it and its result in a convention—a coming together of men whose minds were bent upon a common object. Now, men could not meet without sooner or later exchanging experiences. Book wisdom was not so practical as actual experience, and the men one met at photographic conventions were largely men of photographic experience; tyros there might be, fossils of prejudice also, but still you found the majority were men whose experience was material, the result of knowledge assimilated, which had become part of themselves. Hints from men like these were valuable, and they could not, therefore, attend a photographic convention and go away no wiser. They derived ofttimes very quickly the results of a year's labour. The Convention at Shrewsbury was no exception to this rule. Not from papers so much as from contact on excursions, casual meetiogs with notables in one or other departments of practical photography, did one benefit, and he would like all who heard him to avail themselves of the opportunities afforded by the coming Leeds meeting for economical reasons as well as others. He hoped they should have above 200 members of convention, then, with a similar number of strangers, the city will break the record. Mr. C. M. Hayes, in the *St. Louis and Canadian Photographer* of last month, gave the following recipe for getting the greatest good out of a convention: "Mix a little application with a vast deal of comprehensive listening, add willingness to learn. When this is in the right condition, flavour it with a determination to profit by what you hear and see." The tenth Convention was held at Shrewsbury, the previous ones being held in London, Dublin, Derby, Birmingham, Edinburgh, Bath, Plymouth, Chester, and another town. What struck him at Shrewsbury was the variety of the place itself, the excursions to various places around, and the amount of detailed arrangement, which must necessarily have fallen on the local Committee, far more than would be the lot of the Committee over which he had the honour to preside. This multiplicity of attractive show places led to the Conventioners being divided into somewhat small parties. In the Leeds Convention he thought they would find larger parties would assemble, simply because there were fewer places in their immediate neighbourhood—plenty of railway journeys, but few by road. The Convention might be looked upon as partly of a business and scientific character, but the social element had, after all, the strongest hold on the community. Fifty per cent. might attend the business meetings, ninety per cent. the reception, and about twenty per cent. the scientific papers, the social function being the attractive feature. Here they witnessed the reunion of old friends, every one doing their best to make the meeting agreeable. Sometimes a jarring note was struck, but it only prepared the ear in a Wagnerian fashion for fine harmony, to say nothing of uproarious merriment. While introductions went on apace at the meeting-rooms at headquarters hotel all day on Monday (such introductions being obviously desirable), still the badge of membership was always a passport to free conversation, and it was considered the proper thing to wear the badge on all occasions during the Convention. After detailing the week's programme at Shrewsbury, the lecturer said he took the opportunity the other day of suggesting to Mr. Ives, of Philadelphia (the apostle of colour photography), how glad they should all be to see him in Leeds in July, and he said he would try to come, when he hopes to again have the pleasure of seeing his triple electric lantern for colour projection, as used in his demonstration at the Photographic Club in London on the 4th ult. There was a large gathering of Conventioners that evening. At the close of his address, Mr. Walker further entertained his audience by showing, by means of the oxyhydrogen light, 145 pictures of Shrewsbury, its inhabitants, its surroundings, and Convention visitors. Many of these slides were of great historical and architectural interest. Not a few were contributed by Messrs. Washington Teasdale, J. S. Teape, T. C. Hepworth, W. D. Welford, and Mrs. Catherine W. Ward, for the loan of which transparencies the lecturer acknowledged his indebtedness.

Liverpool Amateur Photographic Association.—The first excursion of the season took place on Saturday, March 28, when a large party, including several ladies, journeyed to the pretty village of Bidston, under the leadership of Mr. H. Holt. Unfortunately, the weather was all against good results; but, in spite of this, many good pictures were obtained, and the outing greatly enjoyed.

Sunderland Photographic Association.—This Association has, during the past month, made a record for itself in the number of specially interesting meetings arranged, all of which have been well attended. On the 12th Mr. W. Parry, of Shields, gave a paper on the retouching of both landscape and portrait negatives. On the 18th a non-competitive Exhibition was held, confined to members, when about 300 prints were hung, besides albums and stereoscopic slides. A number of lantern slides were also shown in the lime-light lantern. On the 26th Mr. John WATSON, of Newcastle, read a paper on

ROUGH-SURFACE PRINTING PAPERS,

treating of platinotype, mezzotype, Venus paper, &c. The chief attraction of the month, however, was the lecture, delivered on the 31st, by Mr. H. SNOWDEN WARD, on

THE RÖNTGEN X RAYS,

which was listened to with great delight by several hundreds of persons. At the conclusion of the lecture a child was brought which had run a needle into its foot. This was successfully radiographed by Mr. Ward, the result showing the position of the needle.

Edinburgh Photographic Society.—March 26, Mr. J. C. Oliphant, and afterwards Mr. A. Eddington, presiding.—This meeting is usually devoted to the exhibition of lantern slides, the work of members, done during the past season, and on this occasion about 160 slides were shown, Mr. JAMES PATRICK reading the notes in connexion with them. The exhibition of slides being over, Mr. H. SNOWDEN WARD gave a lecture on

RADIOGRAPHY.

Mr. Ward showed the latest improvements which had been made in the apparatus used in connexion with the New Photography, among others an improvement which he had himself made in the form of the vacuum tube employed. A number of slides were shown to illustrate the lecture, many being positive, instead of the usual negative, transparencies. Perhaps the slide which attracted the most attention was one made from a photograph taken by Mr. Ward himself, showing a child's hand with a supplementary thumb. By means of this photograph the doctors were enabled to decide whether amputation was advisable or not.

April 1, Monthly Meeting, Mr. J. Anderson presiding.—Mr. J. Ivison Macadam, F.R.S.E., F.I.C., F.C.S., gave a lecture on

Light,

using the lantern [to illustrate. After the lecture, for which Mr. Macadam was heartily thanked, the medals won at the recent Exhibition were presented,

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is take of communications unless the names and addresses of the writers are given.*

FLUORESCENT SUBSTANCES IN X RAY PHOTOGRAPHY.

To the Editors.

Gentlemen,—For the last few months I have not been in the focus of X rays, and consequently not familiar with all that has been published on the subject. I note that Mr. Edison has been experimenting with various substances to render these mysterious rays visible, and that he has succeeded by the use of a calcium preparation. This reminds me that about ten or fifteen years ago I suggested and published some experiments I made with luminous calcium sulphide added to an emulsion of silver bromide, with the view of increasing its sensitiveness. This I succeeded in doing to a remarkable degree, but difficulties arose that seemed almost insurmountable. The only person I heard of who took some interest in the process was Mr. T. Bolas, and he suggested a vitreous preparation of the sulphide, doubtless to prevent a chemical action between the silver and sulphide. My object in penning this is to suggest that great rapidity, or some other effects, may take place by passing the X rays through a layer of the phosphorescent calcium sulphide.—I am, yours, &c.,

Monte Carlo, April 4, 1896. A. L. Henderson.

THE ARTIGUE PROCESS.

To the Editors.

Gentlemen,—In the last issue of your Journal, Mr. "Dogberry" gives us some interesting theories about the bichromated gum process. They are but theories; the whole discussion lies in a nutshell.

Mr. "Dogberry" allows that bichromated gum can give detail, but he maintains that it cannot give gradation and half-tones. I maintain that it can yield gradation and half-tone as well as any other process.

I have worked on this process patiently for more than a year; Mr. "Dogberry" has not. He gives us theory; I can talk from practice. He can show me text-books, but I can show him prints, and shall be glad to do so, if he will favour me with his real name and address.

I am certain that this gentleman, after having seen properly developed prints on properly coated paper, will go back on his wholesale condemnation, and allow that the delicate gradation of the moirée and the delicate rounding of a plump cheek are not forbidden to the worker of the bichromated gum process. If it *was* forbidden, nobody with the least artistic feeling would either use or advocate the process.—I am, yours, &c.,

13, *Rue François I., Paris, April* 6, 1896. Robert Demachy.

KINETOSCOPY ON THE SCREEN.

To the Editors.

Sir,—I have read the letter in your issue of the 27th ult. over the name R. W. Paul, but I decline to enter into a wordy contest with him. I will therefore content myself with a few statements.

Towards the latter end of 1894, Mr. H. W. Short (the Mr. S. of your correspondent's letter), who was a constant visitor at my house, informed me that he knew a man who was making Edison kinetoscopes, and who would do anything to get films, as the Edison Company would only sell films to purchasers of their machines. I believe that no patents were taken out on the Edison machine, the Company relying on the difficulty of the successful making of films, and, as machines were of no use without films, they made it a stipulation with the sale of filme that they were only to be used with their own machines.

Mr. Short knew that I had invented an apparatus for taking (or printing, the principle is interchangeable) a number of photographs in rapid succession, and suggested that, if I were agreeable, he would introduce me to his friend, who would at his own cost make any machine I required, provided that I would supply him with films. Accordingly, Mr. Short introduced me to Mr. Paul. Mr. Paul admitted to me that he had no idea how to make such an apparatus, but that he would work out my ideas for me. I accordingly showed Mr. Paul how the thing could be accomplished, and made sufficient drawings to enable him to work the machine out. From that date until the machine was finished I attended at Mr. Paul's workshop every evening, modifying and superintending the manufacture of this machine. Mr. Short was only present on rare occasions.

I showed Mr. Short Mr. Paul's letter in your issue of the 27th ult., and he seemed very much surprised, and solemnly declared to me that he (Mr. Short) had not the faintest idea how to set about making such an apparatus before he saw my models and drawings, and he was equally certain that Mr. Paul had not; and, further, that he (Mr. Short) had had nothing to do with the designing of the machine.

Mr. Paul's letter would give your readers the impression that a kind of partnership existed between Paul and myself, and speaks of "our first saleable picture."

The truth is that, during the construction of the machine, Paul spoke of putting a large sum of money into the manufacture of films. I expressed myself willing, under such conditions, to give him a share in the venture, but, to my utter astonishment, when the machine was finished, Mr. Paul claimed a half share in it, and this without the slightest intention of putting a sixpence into it. I very well remember Mr. Short's surprise at this claim of Paul's. I finally agreed to appoint Paul agent, Paul agreeing to take a minimum number of films. Later on, Paul said he could not sell the minimum number, and so it became necessary for me to make other arrangements, which I accordingly did, having first cancelled the agreement with Paul.

If Paul thinks that he has any rights in the boat race or any other of my negatives, I would suggest that he makes copies of same in any shape or form, and publishes or makes any use whatever of such copies; we will then have an opportunity of deciding whose property they are.

In conclusion, I would only add that Mr. Paul has never seen one of my negatives, and has no idea, so far as I am aware, how I print and develop my pictures (my printing machine, which is a special one, being exclusively designed by myself and made on my own premises), my methods of handling film being also my own invention.

Apologising for trespassing on your space, but I could not allow such a letter to pass without laying the facts before you,—I am, yours, &c.,

Birt Acres, F.R.Met.S., F.R.P.S.

THE CATHODAL PLATE.

To the Editors.

Gentlemen,—We notice that on page 211 of your last issue you regret that little has been done in the direction of providing a plate for use with the Röntgen X rays. We would therefore bring to your notice our Cathodal plate, which we have specially manufactured, and are introducing for this work. This plate is made according to suggestions from Professor Oliver Lodge, and we hope it will greatly help the workers in this new photographic field.—We are, yours, &c.,

B. J. Edwards & Co.

The Grove, Hackney, London, April 7, 1896.

THE METRIC SYSTEM IN AMERICA.

To the Editors.

Gentlemen,—With reference to the above, you mention that several attempts have been made to introduce the metric system into photography, in this country, without success.

One cause for this is the inertia of the makers of plates, &c. For myself, I will *not* use grains, drachms, and ounces, which convey no sense of proportion, to my mind. On this account, I have asked several first-class firms to print the formulæ, which they recommend for their plates, in metric measures. In each case, the reply has practically been that they should like the metric system to be used exclusively, but that there is great difficulty, owing to the existence of weights and measures on the present system (or want of system), and that most photographers are accustomed to their use. I, personally, object to being coerced into using such a jumble as the apothecaries' weight, but should not desire to interfere with any one continuing to use it if so inclined. I would therefore suggest that plate-makers should give their formulæ in both measures, until the demand for the old method ceases.

If scientific writers would adopt the same plan, the value of their writings would be enhanced.—I am, yours, &c., Chas. Louis Hett.

March 31, 1896.

PHOTOGRAPHERS AND THEIR ASSISTANTS.

To the Editors.

Gentlemen,—In your issue of April 3 some very sound advice is given to assistants seeking employment. Much advice has been given—at different times—regarding specimens; but, may I ask, is there no need for a word of advice to masters? or is it a foregone conclusion that assistants are always to blame?

Your advice respecting marking specimens and enclosing stamps is very good, but even there I have found those, who will not, even under threats, restore the specimens sent. I think too it would be a boon to assistants out of employment if the advertisements were a little more explicit of the wants of the advertiser, and stated that important item, the wages to be paid, and, unless exceptionally long, the hours per day or week to be worked. In following the situations vacant from week to week, I often notice such advertisements as "Wanted————permanency to suitable man;" what kind of person is wanted I cannot tell, it certainly is not human, judging by the regularity some firms advertise the same want

Some as regularly as the seasons have their advertisements, and always for permanencies. Assistants in work would do well to note such firms and beware.

Again, why should any respectable firm decline to state name and address? Often, and especially with assistants who are married, the distance to be travelled is a matter of grave importance, and, had the assistant known the address, his specimens might not have been sent, and so saved that awful trouble of being returned.

To masters I say, State what you require, rate of pay and working hours, and honestly whether for permanency or season.

To assistants, Don't answer, and especially don't send specimens to constant advertisers or advertisements under cover, avoid all such, and don't send specimens above your average work; your average work is wanted, and your average specimens are least often stolen or "mixed."

There always will be the unscrupulous ones who will have an assistant travel from one end of the country to the other for two or three months' work, and assistants who over-state themselves, and are consequently soon "out" again; but much good may be done and trouble saved if those wanting assistants and those requiring situations, would each state clearly in the first instance what is required.

Those who act honestly and fairly are not the ones to be always changing or advertising; assistants in the present condition of trade are only too pleased to stay where they are treated respectably.

PROVINCIAL OPERATOR.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

L. Varney, Bridge-street, Buckingham.—*Photograph of John Locke Stratton.*

F. R. Robinson, 138, Anerley-road, S.E.—*Two Photographs of Rev. Joseph Halsey.*

William J. Bisbop, 15, Maygrove-road, Brondesbury, N.W.—*Photograph of Ribbon Lightning.*

J. Horsburgb, 131, Princes-street, Edinburgb.—*Two Portraits of the Most Rev. Angus Macdonald, D.D., Roman Catholic Archbishop of Scotland.*

RAYS.—C. RICHARDS. Your medical coil and battery are quite useless for experiments in the "New Photography," even if you added two more cells, or even half a dozen more, for that matter.

MOCK PLATINOTYPES.—SUSPICIOUS. The print sent is not a platinotype but a bromide print. If you immerse one of the others in a solution of bichloride of mercury, you will find the image will disappear. If it were platinum, there would be no change.

YELLOW TONES.—S. SHARMAN. If the gelatine prints sometimes turn out all right, and at other times they are "yellow, and of a bilious colour," it is clear that the combined bath is not in proper order. Why not use the sulphocyanide toning bath, and tone and fix separately?

REPAIRS.—M. McE. If the premises are held upon a repairing lease, the tenant will have to do the repairs, even if the damage is not done by him or his *employés*. The landlord is in no way responsible for the damage caused by mischievous or evil-disposed people from the outside—that is the tenant's affair.

COPYING.—T. RAYNOR. The reason why you cannot get the image sharp when it is the same size as the original is that the camera does not extend sufficiently for the lens used. Either a shorter-focus lens or a longer camera is necessary. In copying same size the camera must extend to double the equivalent focus of the lens.

PHOTOGRAPHS ON CHINA.—W. WRIGHT asks: "Can you tell me the way to put photographs on china?"—The best way is the carbon process. Develop the picture on flexible support, and then transfer it to the china, which has previously been coated with gelatine containing a little chrome alum. Any manual on the carbon process will give working details.

TACKY VARNISH.—T. HANDLEY. As we do not know the composition of the varnish, we cannot say why it remains tacky instead of drying hard. Neither is it possible, without that information, to say what can be added to it to remedy the evil. The negatives, however, are not spoilt, for, if the varnish be cleaned off with spirit, they can be revarnished with another and harder varnish.

TONING.—E. F. PEALE writes: "I am glad to find I can get as good results with the separate solutions (toning and fixing), which you gave reply to a little time back. I can get better results if I place prints into toning without washing. Is there any harm in doing so?"—We certainly recommend the prints to be thoroughly washed before they are put into the toning bath, on the score of greater permanency.

TAX ON VEHICLE.—R. W. writes: "I have two places of business—towns five miles apart—and do a good deal of outdoor work. Last year I started a horse and trap to help me in the business—going from town to town, and conveying the apparatus for outdoor jobs. It has a cover, removable, on which my name is painted. This year I am taxed for it. Is that legal, as I require the horse and trap for my business?"—If the horse and trap is used exclusively for business purposes and no other, it is exempt; but, if it is occasionally used for pleasure, it is not.

CARBON PRINTING.—L. E. X. If the glass is clean, and it is well rubbed over with French chalk before the collodion is applied, there will be no difficulty in stripping the pictures off when they are *dry*. We imagine, from your letter, and as you do not care for the high gloss, that you have been trying to strip them before they are perfectly dry. If that is so, it is the cause of the failure. Let the pictures become perfectly dry before they are stripped; the high glaze can be destroyed afterwards by simply putting them in water for a few minutes, and then re-drying them.

COPYRIGHT.—WOODBURY PERMANENT PHOTOGRAPHIC PRINTING COMPANY write: "Having some recollection of a report of a case in your JOURNAL in which an operator claimed copyright in a negative made by him while in the employ of some persons who duly paid him for the same, and who was non-suited in his action, we should feel obliged if you could inform us where we could obtain a report of the case, or one of a similar sort."—We have no recollection of such a case having been taken into Court. Possibly some reader may be able to give the desired information.

PRINT CRITICISM.—ALPHA writes: "In your issue of February 7 you criticised some prints for me, so I venture to trouble you with a few more prints for criticism and advice."—In reply: 1 and 2. Fairly good studies of river scenery, that would have been improved by the addition of suitable clouds. 3. Poor in selection. 4. A very good study of children, but, in our humble opinion, vignetting for groups is best not attempted. This and No. 5 would probably have gained by being printed on a surface paper. 6. An excellent bit of interior work. 7. Spoilt by the vignetting. 8. Extremely good.

LENS, STYLE OF PORTRAIT.—FOCI puts the following queries: "1. What is the most suitable length of focus for lens to take cabinet head, such as frontispiece in ALMANAC? 2. What is the shortest lens (focus) that it is possible to use, having an eye to good results (artistic)? 3. What is the style of head known as the Richmond head?"—1. Twelve to thirteen inches. 2. This focus lens is very suitable for cabinet-size pictures, and one of shorter focus is not to be recommended if artistic pictures are desired. 3. Vignetted heads, about life size, slightly tinted, worked in the style peculiar to the late Mr. Richmond.

WATER SUPPLY.—S. W. B. says: "I am a photographer in town, and do the printing in the suburbs. The house there is a large one, and is very highly rated, and the water rate is based upon the rating of the house. As I use the water for business purposes, can I not compel the Company to supply a meter, and charge according to the quantity used?"—Yes, we believe you can; but we should advise you not to do so, for, if you did, you would probably find your water bill considerably increased, particularly if you wash the negatives and prints in running water. We strongly suspect that, if the Company knew that water was used for business purposes, they would compel you to have a meter and pay accordingly.

DEVELOPING.—J. B. WEBER says: "I have lately been using a very slow developer for snap-shots, as recommended by various papers some short time ago (a very dilute pyro developer), and the negatives are pretty good, but the gelatine is too much coloured yellow by the process. I have tried citric acid, but in vain. The negatives remain six to eight hours in the pyro solution, and under-exposed plates show more details than a rapid developer could produce. With more exposure, or rather better light, the negatives get a little too dense or opaque, which is made still worse by the yellow colour the gelatine gets in the bath. Can you suggest a remedy?"—Clear the negatives in a bath of saturated solution of alum, 20 ounces; hydrochloric acid, 1 ounce.

LINE DRAWINGS FROM PHOTOGRAPHS.—ALBERT STRAUSS says: "Some time ago (perhaps two years or more) there appeared in your JOURNAL a short description of a method by which a line drawing in Indian ink could be obtained from a photograph on ordinary drawing paper. The paper was salted and sensitised, and a print taken, which was then gone over with Indian ink, and afterwards dissolved away, leaving the line drawing only. Is it too much to ask for a repetition of the paragraph?"—We cannot trace the paragraph. After having traced the outlines in Indian ink, the remaining parts of the photograph may be obliterated by converting them into silver bromide or chloride and dissolving out in hypo. Or the image may be simply bleached by means of mercuric chloride, which thus gives black lines on a white ground.

LENS—SHUTTER.—COLLEGE asks: "1. Will you kindly give me your advice as to a lens for a hand camera? I am unable to decide between Dallmeyer's stigmatic, working at *f*·4 focus, 5½ inches, and a Zeiss, working at *f*·6·3. I want the lens for general work, but principally landscape and street scenes. Does the lens at *f*·4 give as great a depth of focus as a lens at *f*·6·3? 2. How short an exposure is necessary to obtain street scenes that are quite sharp, showing no motion? 3. Is the Thornton-Pickard special instantaneous shutter as rapid as any shutter I can get, working in front of the lens? Would you recommend this form of shutter?"—1. A lens with an aperture of *f*·4 will not have the same "depth of focus" as one with an opening *f*·6·3. 2. About the fiftieth of a second will give a sharp picture. 3. Yes. It is a very good shutter indeed.

*** Several answers to correspondents, Editorial Table, and other communications unavoidably held over.

JOURNAL OF PHOTOGRAPHY.

No. 1876. Vol. XLIII.—APRIL 17, 1896.

Contents.

EX CATHEDRÂ.

It is high time, we think, that a protest should be uttered against the class of illustrations appearing in many publications which depend on photography for the means of filling their pages with pictorial matter. It appears to be the aim of the conductors of these publications to get as near as possible to the line which separates riskiness of subject from downright indecency without actually overstepping it, and they seemingly experience no difficulty at all in obtaining negatives and half-tone blocks of subjects, the one and only effect of which can be to pander to and gratify the depraved appetites of the unCleanly and prurient-minded patrons of the cheap bookstall.

* * *

That third-rate music-hall artists, theatrical chorus girls, and vain females of that kind should freely accord photographers the "privilege" of photographing them, and pose, suggestively and scantily garbed, before the camera, with the certain knowledge that the resulting "picture" is to be circulated broadcast throughout the land, is indeed pitiful to contemplate; but we are less sorry for these coarse-minded libels on their sex than for the photographers and journalists to whom the conception and execution of such deplorable examples of modern illustrations are due. Nowadays, for a penny, the youth may obtain across the counter of a respectable bookseller's shop a number of "photographs" of vulgar actresses, vulgarly posed and vulgarly attired, which in former times would, happily, have cost much more, and, as a rule, were only obtainable in the restricted market of Holywell-street, Strand. These productions, moreover, have not even the saving feature of being artistic in arrangement or treatment; they offend against the moral and æsthetic sentiments, and rest their *raison-d'-être* solely on their close proximity to indecency. Even on the comparatively low ground of the considerations due to and demanded by public propriety, we are confident that no sensible man of the world will quarrel with our objection to the publications we are alluding to, and which it is not necessary to particularise.

* * *

We are sorry that the beautiful art of photography should be prostituted in this manner. The remorseless fidelity of the lens and dry plate confers upon such illustrations a degree of unmitigated realism which a draughtsman (and some members of this class of artists are just now, in certain papers, sailing dangerously near the wind) would tone down or avoid. That one of the papers we have in mind will ere long give publicity to a half-tone phototype which results in a prosecution, is our aspiration, for then, probably, a check will be given to the dissemination of the class of illustration we are referring to, and the reproach, that photography and photographers are responsible for the production of pictures that are only published by reason of their offensiveness and vulgarity, will no longer hold good.

* * *

The Annual Conference of the Camera Club will open on the 27th inst. Besides Captain Abney, the President, it is expected that Lord Rayleigh, Mr. Bothamley, Mr. Chapman Jones, Mr. Pringle, Dr. Eder, Mr. W. K. Burton, and Professor Norman Lockyer will take part in the proceedings. We learn from the Club *Journal* that apparatus for work with the Röntgen rays is at the disposal of members on the Club's premises. "It is also nothing but right," says the *Journal* with delicious complacency, "that the leading photographic Club in the world should show the way in matters of this kind."

THE new season's *Handbook of Imperial Plates, Papers, and Films* has been sent us by the Imperial Dry Plate Company of Cricklewood. Useful information and hints with regard to the manipulation of the Company's sensitive preparations are given; and there are three articles, one by the Rev. F. C. Lambert, on "Outdoor Photography;" a second by Mr. E. J. Wall, on "Hints for the Dark Room;" and a third by Dr. Acworth, on "The Choice of Developers." We have read all three articles with great pleasure, for they are pithy and practial.

* * *

A WELL-KNOWN professional photographer, who was recently sojourning in Belgium, wrote us from there that he came across a photographer working a 12 × 10 snap-shot camera (very light), made by Loman, of Amsterdam. It was focussed by means of a reflector somewhat like the Vanneck, so that the picture could be seen until the instant of exposure. He was using a Goerz lens, working at *f*-16. We have been for some time expecting a development in the size of hand cameras, but we scarcely anticipated yet a while hearing that one of such comparatively mammoth dimensions as 12 × 10 would come into use.

* * *

MR. F. K. HURMAN, of 2, St. Nicholas-buildings, Newcastle-upon-Tyne, informs us that the partnership heretofore subsisting between Mr. E. W. A. Schumann and himself has been dissolved by mutual consent, as and from March 28 last. The business will in future be carried on by Mr. Hurman alone.

* * *

THE Britannia Works Company send us two neatly got-up and instructive little pamphlets relating to the use of P. O. P. and the prices of their plates and films, and at the same time they make the following remarks with reference to the suggestion of a photographer, which we noted last week, concerning the provision of P. O. P. cut to four inches by five and a half inches. Our correspondent will see from the Company's letter that his wants have been anticipated: "Will you allow us to point out to a 'Practical Photographer' that we have listed and sold the size he names, with other professional sizes, for the last four years. Further, as you will see by our price-list, we pack *all* sizes, in gross boxes, for *professional use*, at popular prices. If your correspondent will write to us on a postcard, we shall be happy to give him full particulars."

* * *

A FRIEND in New York has favoured us with some copies of the *New York Journal*, which waxes eloquent over Edison's "greatest gift to science." It is to be a gift to the scientific fraternity, we are informed, and the great genius, with marvellous magnanimity, not only declines to secure a patent for his invention, but he has given the right to manufacture it to a former *employé*. This "invention" is, of course, the fluoroscope. We trust that Mr. Edison's fortunate *employé* will not have cause to set no higher value on his acquisition than that usually bestowed on most things obtained at the same rate of payment. It is a relief to turn from the indiscriminate and unearned adulation of our New York contemporary to the admirable paper by Mr. Herbert Jackson that appears in the *Chemical News*, of March 27, wherein that gentleman modestly narrates his experiments with several of some three hundred substances he has been experimenting with for two years in connexion with the examination of opaque objects through which the radiations from excited Crookes' tubes are allowed to pass. Mr. Edison is to be felicitated on his condescension in abstaining from patenting his invention.

PRISON PHOTOGRAPHY.

SOME time ago we commented upon a new regulation that was made with regard to the photographing of prisoners. The regulation is now in force, and each prisoner is photographed in two positions on the same plate, one a direct profile and the other a direct full face, with the hands spread out on the front of the chest. These are the regulation positions, and the operator has no option in the matter. Why these set poses were adopted is because the powers that be at New Scotland Yard think that these views of the face afford a better means of identification than any others. Experienced portrait photographers, with some features, would, nevertheless, think otherwise.

Police photography, if one may judge from the portraits that are sometimes shown at the police stations of persons "wanted," is capable of considerable improvement. The portraits are printed from process blocks, together with the letterpress description of the culprits; but, however good the blocks may have been, they are completely ruined, as many other blocks are, in the printing and by the paper employed, which seems to be of the commonest description. Even that is made worse in some of the examples we have seen through the printing being done on the back—the web side—of the paper; indeed, some of the prints are mere blotches, and, instead of aiding the police, they are quite as likely to mislead them.

Portrait-process blocks always require careful printing on suitable paper, and there is no reason why they should not be so dealt with, except the cost. That need not, however, be greatly increased, as the portraits are but small, and they might be printed separately on good paper and mounted on the printed bill afterwards. An objection might be raised to that on account of a risk of the portrait coming off if exposed in wet weather. This can, however, be avoided by employing an insoluble cement, such as glue containing a little chrome alum or bichromate of potash, which would be rendered insoluble by exposure to light, or by a little formalin.

Stereoscopic Sciographs.—At a recent meeting of the Paris Academy of Sciences, MM. A. Imbert and H. Bertin-Sands exhibited stereoscopic photographs obtained by the Röntgen rays.

Invisible Radiations.—M. H. Becquerel continues his researches in this obscure phase of what, perhaps, may be termed light. We have, on a previous occasion, described the effects of radiations from artificial hexagonal blends that he had observed; but in his more recent communications to the Academy he has found, and M. Trovat has had a similar experience, that this body, which at first emitted most powerful rays, capable of readily passing through opaque bodies, gradually loses its power, and, after a series of excitations, gradually becomes inert and incapable of emitting any actinic radiation whatever.

Other Phosphorescent Bodies.—M. Becquerel finds that this radiation is of a peculiar nature, for the rays from phosphorescing calcium sulphide, for instance, were powerless to pass through opaque substances.

Invisible Actinic Radiations from Uranium.—M. Becquerel's most interesting work, however, is perhaps his investigations upon the emission from uranium compounds. He finds the permanence of these radiations is prodigious. Kept in the dark for fifteen days, free from any radiations of which we have any knowledge, he yet found the original emission power reduced in but the slightest degree. He considers the phenomena to be one of invisible phosphorescence, if such a term be not a misnomer. It is not all of the uranium salts that fluoresce or phosphoresce. The green uranous salts which he is working with exhibit neither phenomenon, though they act strongly upon the photographic plate through opaque obstacles. One very remarkable effect was obtained with some uranium nitrate, the phosphorescence of which disappears when the salt is heated or melted in its own water of crystallisation. Some of this he melted, and allowed to crystallise in the dark, yet, when placed over a plate covered by thick opaque paper, it acted as powerfully as crystals recently rendered active by light.

He finds the relative opacity of bodies to the rays emitted to be very different from the Röntg-n rays. For example, with a thickness of two millimetres, water was very transparent, solutions of copper nitrate, gold chloride, uranium nitrate, chlorophyll solutions only moderately so, uranium glass was opaque, and aluminium sheet sparingly transparent. Tin was more opaque, and cobalt blue glass more opaque than any of the metals. Also again, unlike the Röntgen rays, he was able to obtain refraction. He placed some uranium nitrate crystals in a short tube attached near to the edge of a prism, then developed the plate (it could not be said to be the image), whereupon he found a distinct trace of a line indicating the edge of the prism, and a diffused effect in its immediate neighbourhood in the place where, if the rays had been refracted, it might be expected that the position they deviated to would be situated. Refraction was thus clearly shown.

Meteorological Predictions up to Date.—We are all familiar with the daily weather forecasts which we hunt for in the pages of our daily papers, where they appear with regular irregularity as to position; but the Americans are about to introduce something far in advance as to ready reference. We read that in a few weeks' time the stamper used at Washington for cancelling the postage stamps of letters, &c., in transit—which will, of course, be changed daily—will impress upon the stamp the weather forecast for the day, so that, instead of the irritating search in the newspaper columns, the anxious searcher after meteorological vaticination will merely have to look at his morning's correspondence to find all he requires.

New Source of Platinum.—The precarious nature of the supply of platinum was well shown a year or two ago, when a small combination was able to "bull" the price of this metal, till from a sum below 30s. an ounce it rose by leaps and bounds almost to the value of gold. It will therefore be good news to photographers that a new source of supply has been discovered of such large area that it may fairly be expected to bring down the price to a level never before reached. We read that in New South Wales a bed of platiniferous lead over a mile long has been discovered. It has been known for some time past that the metal was to be found, but it had not been properly worked. It is stated that the platinum is to be present to the large extent of 75 per cent.

Another Big Telescope.—These monster instruments appear to be part of the scientific achievements distinguishing the end of the century, and we are promised the advent of a new one under novel conditions of introduction. Hitherto, a princely benefactor has been the inspiring genius of their creation, but in this new telescope the fees of visitors are looked to, to take the place of millionaire donors. At the Berlin Exposition, which is to open next month, and continue for five months, it is proposed to exhibit in the rough one of the enormous objectives which has been successfully cast by Dr. Schott, and it is expected that enough money will be raised to enable this glass to be purchased and polished. The instrument is partly completed, but the largest objective, 110 centimetres in diameter, has to be paid for and polished. The mounting is arranged for the use of two separate objectives, the one already finished designed for precise visual work, and the other, of larger area and shorter focus, for photographic.

Forthcoming Sale of Old Masters.—The *Standard's* German correspondent says that one of the finest collections of paintings in Berlin is to be disposed of by auction at Cologne on the 28th and 29th inst. It consists of some two hundred and twenty pictures by old Italian, German, and Dutch masters, a good many of them being masterpieces. Amongst the works are Vandyke's portrait of Charles the First of England, formerly the property of the Duke of Hamilton; Rembrandt's celebrated large landscape, with *Judah and Thamar;* Paolo Veronese's *Catarina Cornaro handing the Crown of Cyprus to the Doge of Venice;* Titian's *St. Agnes,* &c. It is mentioned that hardly one of the great Dutch masters is missing in the catalogue. It will be interesting to see if any of this collection will find a home in this country. Not a few of them, we expect, if they leave Germany, will go to America, as wealthy Americans have been large purchasers of old masters during the past few years.

Colour of Negatives and Retouching.—A not unimportant point in connexion with the colour of negatives, more especially portrait negatives, was touched upon at one of the recent meetings of the Photographic Club, namely the advantage it was to the retoucher to have the negative of the same colour as that of the pencil to be employed in working it up. If the negative is stained yellow, for example, the retouching will be of a different colour from that of the image, and will have a different printing value, and in this way many retouchers, of unlimited experience, get misled in their work, the result being that the retouching shows very conspicuously in the finished print, which was not anticipated by the artist. It is a little surprising that this subject has not, before now, gained greater prominence than it has done. It just occurs to us that, if the negatives are not made the colour of the pencil, pencils can be made the different colours of negatives merely by the use of suitable pigments; but whether the pencil-makers would consider the business worth their consideration is another matter.

Variations in Pyrogallic Acid.—Mr. Cadett is reported to have made a very important statement at the Photographic Club the other evening. It was that in plate speed testing with recent samples of pyro he had found the speed of plates three times as fast as with the Hurter & Driffield standard development, and this led him to suspect that the makers of pyrogallic acid might be mixing with it one of the newer developers, such as metol, or in some other way varying it. He further said: "In any case, he noted the fact that, with some makes, or, rather, with some batches of pyrogallic acid, he got higher speed results than with others." This may possibly account for some of the discrepancies of the relative speed of the same brands of plates at various times in the hands of different workers. It also shows, as Mr. Cowan pointed out, that the committee appointed by the Royal Photographic Society was right in agreeing that the only correct method of speed determination was that one which tested the plates with the particular developer with which they were to be used. *Ergo* Messrs. Hurter & Driffield were entirely wrong in saying that all developers gave the same speed readings.

An Amusing Reply.—Last week we alluded to the amusing photographic queries and answers that often appear in an evening contemporary. In reply to the query, "What is the best and cheapest way to develop an ordinary negative?" a writer says he has used the following for years: "Washing soda (lumps), 2½ ozs.: *sulphate* of soda, 2½ ozs.; bromide of potassium, 20 grs.; hot water, 30 ozs. When cold, decant clear for use. To develop, take sufficient to cover the plate well in developing glass, and add pyrogallic

acid enough to cover a sixpence. Stir with a glass rod, and pour on the plate. Don't hurry it; it is sure to come. Let it come out till all details are well out, and add more pyro till you can hardly discern the subject in safe dark ruby light. Wash slightly, and fix in *hypophosphate* of soda, 4 ozs.; water, 10 ozs.; and clear in alum bath ½ oz. to 6 ozs., or 7 ozs. of water." The italics are ours. No size of plate is mentioned for the sixpence measure of pyro; so, presumably, it will be the right quantity for any size plate. It would be interesting to know how the learner has succeeded with the formula and instructions, also to see the negatives of the gentleman who has used it for years, especially as they are fixed with hypophosphate of soda.

HALF-TONE SCREENS BY PHOTOGRAPHY.

I.

From a theoretical point of view the reproduction of half-tone screens by photographic means, when a good original is available, is a matter of the greatest ease, involving only the ability to work with average cleanness and skill; but, when the process is put into practice, it does not, at the outset, turn out to be quite such easy work as it would seem in theory, and, in fact, to one who has had no previous experience in similar work, the first attempts will, no doubt, prove to be complete failures.

It may be asked, in view of the perfection to which modern diamond-ruled screens have been brought and their comparative cheapness, what inducement there is to resort to photographic reproductions. Of course, for all ordinary purposes and where an original screen is already available, there is no necessity for the photographic substitute, but it is only in large establishments and where unlimited capital is available that there can be any great choice of "rulings" to suit different subjects. It may be that to produce the best result a slightly coarser or finer screen may be desirable or one in which the ratio between black and white is different, but to provide a complete collection of ruled screens would be a very costly matter, whereas to produce them as required by photographic means is not only possible, but costs no more than the price of the materials.

As to the means to be employed, I fancy there can be no two opinions on the subject of the preference for collodion over gelatine films. Though for ordinary process purposes it may be, to a great extent, a matter of taste whether collodion or gelatine plates are the more suitable, I think for actual screen purposes the greater transparency and freedom from colour of collodion give it an enormous advantage over gelatine. Indeed, I have never succeeded even with specially prepared gelatine films in obtaining a screen that was capable of use in the camera, whereas with collodion the clearness and transparency are equal to diamond rulings.

The choice, then, rests between wet and dry-collodion plates, and between the bath and emulsions. Although, no doubt, many old wet-plate workers will prefer to rely upon the bath and wet collodion, I think it can be shown that, for many reasons, a dry film is preferable to a wet one; but, if only for the greater cleanliness in working, and the greater ease with which a dry film free from minute defects can be prepared, the latter will recommend itself; besides which, the dry plate can be used in absolute contact with the screen if necessary. As to the choice between the bath and emulsion, that is only regulated by mechanical conditions. If an emulsion is at hand that will give a film of the needful uniformity, that is free from structure of any kind, and more particularly from mottling and similar unevenness in coating, then the emulsion film will be quite as good as one prepared in the bath; but I expect the average photographer will find it far easier to prepare a film possessing the requisite qualities by sensitising in the bath than by any form of emulsion. I do not mean to say that collodion emulsion is not suited to the purpose, but simply that, in unaccustomed hands, the bath method presents fewer difficulties.

For the purpose in question, everything depends upon the perfect evenness and uniformity of the film, and it is clearly far easier to prepare a structureless and perfectly even film of collodion than of emulsion, since the mere presence of the particles of silver bromide in the latter tend to militate against its even flowing and setting. The collodion, on the other hand, unloaded as it is, either with insoluble silver salts, or with water used in the process of mixing, flows perfectly smoothly, and sets evenly, after which the formation of the sensitive salt in a perfectly homogeneous form, presents no difficulties, assuming, of course, that the collodion in the first place is not over-salted.

If the films are to be used dry, for reasons that will be obvious to every collodion worker, the salting of the collodion will be better if it consist principally of bromide, or perhaps, for a reason I shall mention, solely of bromide. The dry films will, in the vast majority of cases, be developed by the alkaline method, for which iodide of silver has little, if any, value; but the presence of at least a small proportion of iodide in the film adds not only to the cleanness of working, but gives a colour and "body" that materially assist in preventing halation in any form. At the same time, it is quite possible to prepare a film of pure bromide that shall possess sufficient density to be quite free from danger from this source, and that will also be available for use where the "reversal" method is to be adopted, as for making a cross-line reproduction in a single operation. I do not know that the presence of a small proportion of iodide would exert any absolutely injurious effect in a film to be so employed; but, at any rate, it would not be an advantage, and, as the simple bromide film is just as easy to work, it may as well be omitted.

Assuming a simple bromised collodion to be used, the salting may consist of six grains of bromide of cadmium and two grains of bromide of ammonium to each ounce of plain collodion. The latter may be any ordinary wet-plate collodion, the only difference being in the salting. This should be kept at least a fortnight before use, but will be better after some weeks. The solvents should be of the best quality, both as regards purity and strength. The bath should not be of lower strength than forty-five grains to the ounce, and may with advantage be increased to sixty grains. Although with bromo-iodised collodion the latter would be injuriously strong, it is not so with a fairly strongly bromised collodion, which absolutely requires a stronger bath. If the collodion given above be sensitised in an ordinary thirty or thirty-five-grain bath, the film will be thin and transparent, no matter what length of immersion is given; but with a stronger bath, a three or four minutes' dipping will give a rich, creamy, and almost opaque film of great sensitiveness. The bath should be very faintly acidified with nitric acid, and, if "sunned" for a day or two before adding the acid, will be none the worse in working.

Although three or four minutes suffice to produce a rich, creamy film, it is just as well to give a little longer. Upon removal from the bath, the plate must be well drained, in order to save as much as possible of the strong silver solution, and is then transferred to a dish of distilled or boiled rain water, and thence into successive changes of ordinary water, until every trace of free silver has been removed. The perfect removal of the free silver is especially necessary if a "preservative" of tannin, pyro, or gallic acid, be used, but otherwise it is not so essential as in the days of dry plates, that had to be kept for any considerable time. It is better, however, to err on the side of care than in the other direction.

Before drying the film, it is necessary to apply some "preservative" or "organifier," that is, a solution of a gummy character, which serves the double purpose of filling the pores of the collodion film with soluble matter, that prevents its drying up into an impervious skin, and of conferring certain organic properties on the sensitive salt, that assist in giving density to the image. This preservative may consist of almost anything of a gummy or saccharine nature, and for our present purpose, as extreme sensitiveness is not a necessity, the choice is easily made. Nothing answers better than an infusion of ordinary tea or coffee, just as made for drinking purposes, only omitting the milk. A ten-grain solution of tannin, or a two-grain solution of pyro, may also be used when a "chemical" preservative is preferred, but, for general convenience, the tea or coffee will answer every purpose.

W. B. Bolton.

EASTER IN EAST ANGLIA.

The toy railway from Halesworth to Southwold deposited a friend and ourselves at the station of the last named town at dusk on the evening

before Good Friday, and willing hands having taken charge of our photographic apparatus and other belongings, it was not long before we were comfortably installed in the peaceful hamlet, which is perched upon the cliffs that look out upon the German Ocean from the easternmost boundary of the county of Suffolk.

To the intense charm of its reposeful lethargy Southwold adds many other attractions for the wearied town worker. If its architectural features, with the single exception of its imposing church, reflect no lustre upon antiquity, it possesses the unique advantages of having in a marked and welcome degree escaped the advertising adornments of pill and ointment-makers, of being looked upon as beyond reclamation by the Salvation Army, of being left severely alone by the day excursionist and the excitement seeker. People go to Southwold to play golf, to indulge in the sweetness of doing nothing, to escape the irresistible distractions of less inaccessible and more pretentious watering places.

Many people also go to Southwold to take photographs, although in the large and straggling hamlet itself (for it is nothing more) the church —a fine Gothic structure, with a lofty square tower, characteristic of ecclesiastical edifices in East Suffolk—supplies the only work which awaits the camera. Southwold, however, is surrounded by wide-stretching and spacious commons, intersected by dykes and dotted by cattle, which afford every opportunity for the indulgence in pastoral photography of the kind to which Dr. P. H. Emerson accustomed us many years ago.

On Southwold beach the trained eye will discover many opportunities for picture-making by photography. Nestling under the cliff are the quaint and curious shanties of the fishermen, who, picturesque and simple-minded to a degree, and far removed from the sophisticating influences that beset their brethren on other parts of the coast, prove more docile and easily managed sitters, and provide one with plenty of scope for attempting artistic figure studies. The boatbuilder at work in his shed, the fisherman mending his nets or tarring his shanty, the inevitable group of weedy longshoremen at their eternal and almost sole recreation of gossiping and smoking, from which they seek temporary respite by ever and anon scanning the offing in their own peculiarly deliberate but mysteriously interested fashion, are ready to the photographer's hand, and almost dare him to produce negatives that do not possess at least the elements of pictorial charm or local interest.

Fishing is the one industry upon which the prosperity of Southwold appears to hinge, and the incoming of the little craft, with the subsequent examination and basketing of each sea toiler's small harvest at the boat's side, yields the photographer excellent chances of attempting studies full of natural variety. The man with the camera, however, has to be quick of perception, and no less expeditious in action, for these interesting incidents of the shore are of comparatively brief duration, and your Southwold fisherman, so soon as he has analysed his catch, evinces a laudable anxiety to set about disposing of it. Still, the men are a simple, kindly, albeit independent and self-respecting race, and a morning or two spent in their midst is certain not merely to be repaid by a crop of good studies for the camera, but to give additional pleasure to the companionable visitor who may delight in listening to the local dialect, and to interest himself in the ways and manners, the joys and grievances, and the legendary lore of the Southwold fishermen.

Northward of Southwold, and across a breezy stretch of common land, from which it is separated by a calm and sluggish river, the Blythe, lies the well-known village of Walberswick, which, with its red-roofed cottages, its flats and shallows, its charm of colour and picturesque grouping, is beloved of artists and photographers alike. For those who take delight in the more placid and not obvious photographicable beauty to be found in subjects relying for their success upon the introduction of marshy excerpts, reeds and ruts, misty effects, and clouds rising up from the quiet distance, into which the silent river steals away from this old-world little village, the vicinity of Walberswick is the ideal spot in which to idle away a day or two in company with a camera and a few dozen plates. It is essentially a place where one is called upon to make one's pictures, and hence it may be said to appeal rather to the photographer with some approach to cultivated perception in the selection of subjects than to the very numerous class which demands its picturesqueness ready-made, and, as it were, plainly labelled, "To be exposed upon."

During our stay at Southwold, we encountered several photographers whose names are household words in the world which interests itself in pictorial work, and we have little doubt that we shall make acquaintance with some of the results of their labours at the autumn exhibitions. Both for health-giving restfulness, as well as for the fine field it supplies for the practice of what may be termed the higher branches of pictorial photography, we can cordially recommend Southwold as an excellent centre of a district rich in the unconventional charm of ungroomed natural beauty and picturesqueness.

We availed ourselves more than once of facilities for changing plates kindly afforded us by Mr. J. Martyn, of Southwold, a professional photographer whose excellent portrait and landscape work, as well as the neatness, orderliness, and the apparent excellent adaptation of his studio for the production of good work, might excite envy in the breasts of photographers in much bigger towns.

DISCURSIVE NOTES ON CARBON PRINTING WITHOUT TRANSFER.

[Autotype Notes.]

During the past year or two a good deal has appeared in the photographic press on the subject of carbon printing without transfer, not a little of it being from the pen of Mr. Alfred Maskell, who should be credited with being a doughty champion of the non-transfer system of working. In his communications he has, on several occasions, had a mild fling at the *Autotype Manual*. In an article in the *Amateur Photographer* for the 6th ult., these ideas are reiterated. Alluding to the early workers, its writer says: "The contention that in the carbon process half-tone can only be obtained by the process of detaching the film from the unexposed surface is a notion much fostered in this country by the various issues of the *Autotype Manual* or virtual copies of that manual." The writer then gives Mr. Maskell's method of preparing the paper. This is precisely the same as that published by the late Mr. John Pouncy nearly forty years ago; and, in a recent number of The British Journal of Photography, Mr. Pouncy's son calls attention to the fact, and pertinently asks who is the author of that method?

As I know some experimentalists have failed to obtain an even coating by Mr. Maskell's way of applying it, I will give Mr. Pouncy's method as originally published by him, as it may prove useful to modern investigations. Three solutions are prepared: 1. A saturated solution of bichromate of potash. 2. A solution of gum arabic about the consistence of thin varnish. 3. Vegetable carbon finely ground in water. Mix four drachms each of Nos. 1 and 2 together, and add some No. 3. The paper being laid on a glass plate, "commence coating freely with a broad camel's-hair brush, laying on a copious supply over the whole surface, and then allow the paper to absorb for about two minutes. This done, remove the superfluous liquid thus: Take a painter's 4-inch hog's-hair 'softener,' and work it regularly over the paper, with an alternate vertical and horizontal motion, until the whole presents a smooth, even surface, partially dry. The drying may then be completed by the fire."

That good results can be, and have been, produced in carbon without transfer cannot be denied. Pouncy did show some exceedingly satisfactory prints by his method. I well remember that, at the meeting of Photographic Society in 1858 (and a stormy one it was too), when Pouncy brought his process before it, one of the, then, old workers in photography, and an opponent of the process, had to ask Mr. Pouncy which of two prints from the same negative was carbon and which was silver; and, when told, he remarked that the carbon was a very beautiful result. I just allude to this fact because it has been mentioned more than once lately that it is only within the last year or two that good carbon prints, without transfer, were a possibility.

When the carbon process was first introduced I well recollect that Mr. Pouncy had rather a rough time of it, for it was a pretty general thing at that period for the journals to "take sides." If one extolled a process, it was almost certain to be decried by the others, and so it was with Pouncy's process. *Photographic Notes* championed it, and *The Photographic News* lost no opportunity of disparaging it, and its inventor, both in editorial articles and in anonymous communications, particularly when it was suggested that the process should be disposed of to a certain number of subscribers for the sum of 100*l.*, not a very large amount after all. One of the arguments raised against the process, I remember, was that the pigment could not be got into a sufficiently fine state of division to properly render the delicate tints of a photograph. Another was—and that was a more legitimate one—that it would be impossible to obtain the same delicate half-tones as with silver. This was substantiated in practice unless negatives of an exceptional character were used, and they were not the kind in general vogue then.

There is no question, if Burnett, Blair, and others had not pointed out that, in order to obtain perfect half-tones, the exposure must be made from one side, and the unaltered pigmented coating washed away from the other, that "notion much fostered in the *Autotype Manual*," carbon

printing would never have assumed the proportions it has. When Swan's process was introduced, that of Pouncy was little heard of afterwards. There is, however, very little doubt that, if the transfer operations could be dispensed with, and equally as good results obtained as with them, the carbon would be the most generally practised of all the printing methods.

It is claimed for a process which has been considerably extolled during the last year or two, by some, that it fulfils the above end; I allude to the "Artigue process." That process, however, must not be confounded with that of Pouncy, as described by Mr. Maskell. It is quite a different thing. The paper is differently prepared, and is manipulated in a totally different way. By this method, and with suitable negatives, tolerably good results can be obtained, provided the exposure has been accurately timed. But are the results equal to those obtainable by the ordinary carbon process? Are the tones throughout the scale from the highest lights to the deepest shadows so perfect in gradation as they are by the ordinary process? I must say that, in all the examples I have closely examined, they were not, good though they were. If the scale were true, say, from the shadows to the middle tones, that from the middle tones to the high lights was not. On the other hand, if those from the highest lights to the middle tints were in perfect gradation, then the deeper tints were not. The ordinary carbon process would have rendered them more correctly. Possibly, however, I have been unfortunate in the various examples I have met with. E. W. Foxlee.

VIEW-FINDERS WITH PRISMS OR SPHERICAL REFLECTORS.

Mr. G. F. Fraas describes the following plans of obtaining a bright image without the aid of a screen of ground glass or other material:—

1. By the combination of a lens or lenses with a prism in a suitable mount or setting.

2. By the combination of a lens or lenses with a spherical reflector in a suitable mount or setting.

On looking into the prism, or spherical reflector, at right angles to the axis of the lens directed towards any object, a distinct image may be clearly seen.

A prism only may be used, with or without any mount or setting. I do not bind myself to any particular form of prism, as the sides may be all plane or curved, or combinations of planes and convex or concave curves. The hypothenuse of the prism may be silvered or not, as preferred.

The curved surface of the prism is to magnify the image, and to collect the rays transmitted by the front lens, where one is used.

The most portable and convenient method of setting is a light metal box, but any other material can be used.

The lenses may be biconvex, or plano-convex, or "crossed" convex, as preferred.

The patentee claims:—1. A view-finder having a prism, or prism and lens, substantially as described. 2. In a view-finder for photographic purposes, having a combination of prism and lens or lenses. 3. In a view-finder the combination of a lens or lenses and spherical reflector.

A "SILVER CHROMATE PRINTING PROCESS."

This process is the invention of Herr Hrdliczka-Csiszar, of Vienna, who gives the following description of its *rationale*, and the method of preparing the emulsion:—

The known silver salt paper—for instance the so-called albumen paper, celloidin paper, the various known gelatine or Aristo papers, as also arrowroot and algeine paper and plates—when used for printing or reproducing negatives gives a print whose degree of brilliancy differs according to the kind of paper used; the so-called Aristo paper gives the most brilliant print, but "thin" and "flawy" negatives prepared with such paper yield in every instance but flawy and dull prints, *i.e.*, prints lacking contrast.

According to the present invention, certain substances are incorporated with a silver-salt preparation, and, by means of the resulting compound, good bright prints with high lights may be obtained even from the dullest negatives which cannot be reproduced by the processes at present resorted to. This is effected by adding ferrio-prussiate or monochromic, dichromic, or polychromic salts or chromic acid, or manganates or permanganates to the known preparation; for producing silver-salt paper, a chromate or dichromate of silver is thereby formed, either during the sensitising of the paper or during the preparation of the emulsion.

The printing, toning, and fixing of a ribbon prepared from such paper showed, on being tested in Professor Vogel's photometer, that it printed very rapidly, which in practice signifies that very thin, flawy, and dull negatives yield brilliant prints on such paper.

I shall now describe, by way of example, the employment of the above mentioned chemicals in combination with a celloidin or Aristo emulsion, although, for a person skilled in the art, no further explanation is necessary, seeing that the print is rendered brilliant by adding any one of the substances above mentioned, while the determining of the amount of such substances to be added for producing various degrees of brilliancy, as also the employment of the proper paper or plate prepared according to this invention for a certain flawy negative, is a matter which experience alone can show. First, the known solution of 1·3 grammes of lithium chloride, 1 gramme citric acid, and 50 cubic centimetres alcohol is prepared by heating 4 cubic centimetres of a 4 per cent. solution of celloidin-collodions being then added; 12 grammes of silver salt are now dissolved in 5 cubic centimetres of hot water, 150 cubic centimetres anhydrous alcohol added and then heated to boiling point; the resulting solution of silver nitrate is now gradually poured into the chlorous collodion mixture. The known emulsion of chloride of silver collodion is thus obtained.

According to this invention, however, about 1 gramme ammonium chromate, or bichromate, is dissolved in 10 cubic centimetres of water and mixed with as much alcohol as the solution admits without being made turbid; the other chromates, or compounds of ferric-cyanates may be prepared in like manner. This solution is now allowed to drip into the known emulsion (which is at the same time vigorously agitated) until tests show that positives of the desired brilliancy may be obtained from the thin and flawy negatives to be printed. By following this procedure, it is possible to obtain a series of silver paper or plates of different printing properties.

Aristo paper, which does not print very readily, may also be produced in the same manner. The employment of said salts in connexion with the various salted papers, such as albumen, arrowroot, resin paper and the like, is not so difficult, it being only necessary to add a few drops of the solution of above-mentioned salts to the emulsion preparation, the reaction with the silver nitrate not being effected until the paper is sensitised in the silver bath.

Although it is taken for granted that the silver-salt preparation is known, it may be well to give one of the compositions of 4 per cent. celloidin collodions, *viz.*:—

A { 100 grammes Schering's celloidin dissolved in
2 litres of alcohol of 96 per cent.,
2 litres ether of 0·725 specific gravity; to this is added

B { 100 grammes silver nitrate dissolved by heat in
60 cubic centimetres water and
350 cubic centimetres alcohol (96 per cent.) added.

B is brought to such a temperature that an elimination of silver crystals is no longer perceptible; the following is then added:—

C { 25 grammes citric acid, dissolved in
250 cubic centimetres alcohol (96 per cent.) and then a solution of

D { 12 grammes chloride of strontium,
12 grammes chloride of lithium, dissolved in
250 cubic centimetres alcohol 96 per cent..

Finally, 20 grammes of castor oil and 30 cubic centimetres of glycerine are added.

The above emulsion may be successfully employed, although it will be evident that it may be varied in numerous ways according to the different properties required of same, *i.e.*, according to the particular purpose for which it is destined. As already stated, the success of the present process is by no means dependent on the particular composition of the above emulsion; the emulsion as ordinarily prepared is rendered capable of yielding brilliant prints by adding the attenuating and retarding substances.

An emulsion yielding well-defined and strongly contrasting prints may be easily produced by adding the following substances to a known emulsion, prepared, for instance, in the manner above mentioned. A solution of the additional substances is prepared in the proportion of 1: 10 of the known emulsion and then added drop by drop in the latter until a more or less strong colour is imparted to same; the resulting emulsion is rendered more and more effective by dropping a correspondingly greater quantity of the solution into same. In practice, the additional solution added to the known emulsion is limited by dropping about 8 cubic centimetres of the 10 per cent. solution of chromic acid or dichromate to each litre of the known emulsion and constantly agitating same all the time.

While the afore-mentioned known emulsion registers 15° in Vogel's photometer, on adding 2 cubic centimetres of the chromic solution it registers 10°, on adding 4 cubic centimetres 8°, and 8 cubic centimetres 6°; hence a most effective emulsion is obtained. The same effect may be obtained with ferric-cyanates, manganates, and the like, whether the emulsion is used on paper, glass, porcelain, wood, leather, silk, or like substances.

The following is a good Aristo gelatine emulsion: 100 grammes of gelatine is put for half an hour into 500 cubic centimetres of water and then heat applied until the gelatine dissolves. To this solution is added

20 grammes citric acid dissolved in
100 cubic centimetres of water and
2 grammes seignette salt dissolved in
10 cubic centimetres water; and finally
50 cubic centimetres of a 10 per cent. solution of chloride of ammonium.

The whole is now heated to 40° Centigrade, and a silver solution com-

posed of 30 grammes silver nitrate and 500 cubic centimetres of water at 30° Centigrade added drop by drop to same, the emulsion being thoroughly stirred all the time.

The above gives the ordinary Aristo emulsion, which, on adding more or less of the additional substances, as before described, may be brought to the desired state of perfection. The inventor claims:—

1. The herein-described process of making a silver-salt preparation for photographic purposes, consisting in adding to a known silver-salt preparation substances such as ferric-cyanates or chromates, which attenuate or retard the effect of the resulting emulsion.

2. As new articles of manufacture, silver-salt preparations or paper for photographic purposes prepared from an emulsion made by adding ferric-cyanates, chromates or the like to a known silver-salt preparation.

ON A NEW METHOD OF PREPARING PLATES SENSITIVE TO THE ULTRA-VIOLET RAYS.*

V.—The Development.

The development is carried out solely and alone with pyro and soda prepared according to Dr. Eder's formula (vide *Photographie mit Bromsilber-gelatine und Chlorsilber-gelatine*, 4th Edition, 1890, p. 294)—

I.

Crystallised soda sulphite	100 grammes.
Pyrogallic acid	14 ,,
Sulphuric acid (to neutralise the alkaline sulphite)	6 drops.
Water distilled	500 c. c.

The sulphite is dissolved in the water, the acid added, and finally the pyro.

II.

Crystallised soda carbonate	50 grammes.
Water distilled	500 c. c.

If anhydrous carbonate be used, only half the above will be required.

The developer should only be used greaty diluted, otherwise spots and fog appear on the plates. I use for each volume of pyro and soda solution 3 to 6 volumes of ordinary water and some potassium bromide. The image appears in about twenty to thirty seconds, and is finished in two to three minutes. If the development is carried on longer, fog comes on, notwithstanding the dilution of the developer, and sometimes even earlier. If the image is to show clear glass, then the plate must be washed as soon as the fogging begins, and fixed immediately afterwards. In my experiments the fogging frequently began after the development had gone on for 90 to 100 seconds. If the negative does not come up completely in this time, another plate must be taken with longer exposure. It is no use trying to attain the object by forced development.

It is only by observing this precaution that a clear picture can be obtained with these plates sensitive to the ultra-violet.

For spectrum photographs, which particularly require delicate delineation, especially for bringing out closely packed lines, I have lately followed another method of developing. I take no heed of what appears on the plate—it would, in fact, soon be impossible, because the lines could not be seen in the development on account of their exceeding fineness; so I leave the plate in the developer for a certain time, which I have ascertained by experience. It is true I do not succeed with a single trial. As a rule, the first negative I take in this way does not do, because the lines are too broad, and lines lying together are either massed together or insufficiently separated. In such case I take the negative again. Although I keep to the original exposure, I shorten the development by some seconds. In this way I obtain frequently, but only after the third or fourth exposure, line pictures of a fineness which I cannot obtain with ordinary development. This way of working takes up a good deal of time, but the beauty of the resulting negatives richly repays the great expenditure of time and trouble.

The fogging of the plate can be restrained with potassium bromide, but care is necessary with it. Potassium bromide exerts a decided influence on the size of the silver particles which form the negative or the so-called "grain" of the plate. I take 5 to 10 drops of ten per cent. solution of potassium bromide for 60 to 180 c. c. water, 20 c. c. pyrogallic acid and 20 c. c. soda solution.

With gelatine emulsions, it is assumed that the grain of the emulsion is the same size as the grain of the image. If this is not strictly the case with such plates, as is shown by the microscope, it is still less so with plates sensitive to the ultra-violet rays.

* Continued from page 235.

The negative grain of a plate sensitive to the ultra-violet is in most cases a combination of several, often even of a great many, grains of emulsion, which together form a blackish-brown cluster of varying form and size. The size of this cluster depends on the nature of the sensitive coating and on the composition of the developer. It will be increased by silver iodide, but still more by potassium bromide in the developer. In general, silver bromo-iodide in a developer containing potassium bromide gives a coarser negative grain, while silver bromide in a developer free from bromide gives a finer one.

How much the size of the grain sometimes depends on the potassium bromide is shown by the following uncommon case. I cut a bromo-iodide plate into three parts, and, without exposing to light before doing so, developed the first part without bromide, the second with a small addition of potassium bromide, the last with five times as much, and each until a strong fog appeared. The three plates show on a transparent ground a series of negative grains in turn 0·02 mm., 0·14 mm., and 0·27 mm. in size, besides, it is true, many smaller grains also. All these grains have the form of a disc, and the distance between them increases with their diameter. These plates, especially the coarse-grained ones, quite produce the impression that the silver bromide, which at first covered the ground of the plate, had been used up in forming the larger clusters. Whether, and to what extent, the solubility of the silver bromide in potassium bromide is connected with the enlargement of the grain, I must leave undecided, because I have not occupied myself further with this question.

The gelatine appears to have some influence on the formation of the usually angular or round-shaped negative grain. Silver bromide containing agar-agar gave me coarse, moss-shaped forms.

The size of the negative grain of a bromo-iodide plate developed with a developer containing potassium bromide depends further on the nature of the cause which brings about the decomposition of the developable silver haloid. An unexposed plate developed to the point of fogging, gives the coarsest grain, and an exposed plate the finest; between them lies the grain which is given by a moderately exposed sensitive film.

If the washing of the plate after the first drying is omitted, then it always carries with it a small quantity of potassium bromide after leaving the silver solution, and also certainly some potassium nitrate besides. In this case the appearances are more or less similar to those which follow the addition of potassium bromide. I have not studied the effect of potassium nitrate on development. There is no fear of free potassium iodide in the sensitive film, because, during the precipitation of the silver haloids, it will be completely changed into silver iodide and potassium nitrate before the bromide can separate itself out.

If potassium iodide is added to the developer, then the image appears very quickly, seldom, however, without fog. If the development is not stopped at the right time, the fog increases until the image disappears from sight, notwithstanding that it is still easily visible by transmitted light on account of its unusual density. In most cases the fog begins at the edges of the plate, so that the middle of the plate is also more transparent after fixing.

The quickness with which the image appears and its great intensity, in consequence of which more details are visible in the developer than on a less intense plate, led me at first to the belief that potassium iodide would allow of a notable decrease of exposure; but comparative trials showed that the gain is small. The increase of density is of greater importance. Only the lines developed with potassium iodide have such fuzzy edges that they are badly adapted for sharp measurements. Their grain is enlarged, and, partly on account of the foggy ground, not sharply defined. In other cases, plates which are wanting in intensity and too transparent under the microscope to permit of being distinctly focussed, answer the purpose better if developed with potassium iodide than is otherwise possible.

The addition of iodide to the developer should only be very small, otherwise the plates may become covered in a few seconds with such a thick fog that only the high lights of the image remain perceptible. I use a solution of one per cent., and for each 3 c. c. of pyro solution one to two drops of it.

Potassium bromide checks the foggy tendency of the iodide, but only slightly. With six drops of bromide solution (1 : 20) to 3 c. c. pyro solution, the fogging caused by one drop of potassium iodide (1 : 100) could only barely be checked.

Potassium chloride lessens the fog, but also the sensitiveness and intensity. The disadvantages, unfortunately, outweigh the advantages. It is so at least with silver bromide, with which alone in this case I have any experience (one trial).

A developer containing gelatine tends to a fine-grained image and also

checks the formation of fog. Towards the end of the development potassium bromide may be added without fear of enlarging the grain. If the bromide be present from the commencement, the image acquires great clearness, but comes up slowly. If the plate contains silver iodide, then the grain enlarges under the influence of the bromide. My developer contained 2 c. c. of solution of gelatine (1 . 50) to 3 c. c. of pyro (one trial).

Ammonia employed as a preliminary bath heightens the sensitiveness and intensity of the silver bromide. The lines will be clearer, the ground of the plate lighter, although it shows larger spots than an unbathed plate does. This mode of sensitising does not answer in practice because the bathing (15 minutes in 150 c. c. water and 1 c. c. ammonia) and the subsequent drying take up too much time (one trial).

The general result of my experiments in developing can be summed up —in using a largely diluted developer and little bromide, with a good exposure, but, above all, short development. VICTOR SCHUMANN.

(To be continued.)

PLATINOTYPE PRINTING.

[Dundee and East of Scotland Photographic Association.]

PLATINUM printing is certainly very popular with those who practise this process, and why beginners do not use it more is, I fear, due to the fact that the name at first sight carries with it some suggestion of expense in connexion with special apparatus, such as calcium tubes, rubber pads, hot baths, thermometers and stoves, gas or otherwise.

Those who have up to the present held aloof from the process on this score may at once put these scruples aside, for I assure them that no expense need be incurred in procuring any of the above-named articles, as they are not required in the "cold-bath" process about which I am speaking with you this evening.

There are three things that we look for in any printing process, viz., (1) simplicity of manipulation; (2) beauty and variety of results; and (3) permanence.

Under the heading of simplicity, I may safely say that no process can compete with this one. The image not being altogether a latent one, no actinometer need be used, and there is no single or double-transfer process that the amateur need fear. Nothing could well be more simple than the process of printing, developing, and clearing; there is no toning.

I may here mention that, with a suitable negative, it is possible to print by daylight, develop, and mount a print complete in half an hour. If printing is conducted by artificial light, this time can be reduced considerably, so that I think it will readily be admitted that a process which can be worked so rapidly cannot be other than a simple one.

Under the second heading of beauty and variety of results, I must say that, in using the cold-bath process, we are more or less restricted to black tones. The effects that can be produced, however, with these tones will compare with any other black-and-white process, and, although it may be equalled by the carbon process, it certainly is not excelled by it. Platinum does not enjoy the advantages attendant with the carbon process of almost unlimited choice of tones to suit all the artistic, fashionable, and other outrageous demands made by those workers who wish to establish a school of their own, and hand their names down to posterity as the benefactors of the dealers in photographic apparatus.

Of all the printing processes which we possess, platinum and carbon stand out pre-eminently for their permanency, although I cannot help thinking that the permanence of any process is very much dependent on the substance that the emulsion or salt is coated on. The process itself may be divided into three stages, viz., printing, developing, and fixing or clearing.

I am confining my remarks to platinum paper manufactured by the Platinotype Company, of 22, Bloomsbury-street, London, although there are several other good makers. The papers are of several grades or kinds, viz., H.H. and C.C. are manufactured for the cold-bath process, and refer to the surface, texture, and thickness of the paper. As the paper has a great affinity for moisture, every precaution should be taken to keep it perfectly dry. The paper is put up by the manufacturers in tins which are sealed up, and the contents kept air-tight, and in this condition will keep for an indefinite period. A small supply of calcium chloride is enclosed with the paper. This is done in order that any moisture that may have been in the paper itself, or the tin, at the time of packing, may be absorbed. The calcium chloride having a great affinity for moisture, the contents of the tin are thus protected. As these tins do not lend themselves readily for the purpose of keeping the paper in after once being opened, owing to the fact that it is rather difficult to render them air-tight again, it is advisable to transfer the paper to another receptacle known as a calcium box or tube. This is a box or tube which has a space for keeping a supply of calcium chloride in, in addition to the paper. Specially made receptacles may be bought of the dealers, but they are an unnecessary luxury, as any one can, in a few minutes, make one answering every purpose for a few pence by procuring two tins such as are used for putting up cocoa in, one a little larger than the other. In the inner place the paper, and in the outer space put a small quantity of the calcium; put on the lid of the larger box with a piece of waxed paper underneath, and a tube answering all practical purposes is the result. I may here make a few remarks from my own experience regarding the keeping qualities of the paper.

The paper will keep a considerable time in the maker's tins, previous to being opened, and little, if any, difficulty is experienced in keeping the paper in the calcium tin if the tin itself is stored in a dry atmosphere. The ordinary calcium tin is, however, useless for the purpose if kept in a damp atmosphere, even if the calcium be dried once a week. Indeed, if the paper has to be kept in a damp atmosphere, I prefer to keep it in a tin without any calcium at all, but sealing up the tin as securely as possible, for, if moisture *can* find its way into the tin, the presence of the calcium is only an inducement for it to do so; so that it cannot be too strongly urged upon users to keep the tins in a dry place, and not trust too much to the calcium to protect the paper from moisture. If one is continually using the process through the season, there is no reason why the paper should remain for a long enough period in the tin to deteriorate; but it is advisable to put the tin containing the calcium near the fire occasionally (having previously removed the paper), in order to keep everything as dry as possible. If these points be attended to, there will, I am sure, be no difficulty in keeping the paper in good condition. If, however, it is required to keep the paper for a long period through the winter months, the best method is to wrap the paper up in waxed paper (such as some makers use to wrap dry plates in) and place the whole in the calcium tube, which has been previously dried; the joint around the tin should be sealed up securely with wax, and the whole put away in a cool, dry place. The effect on the finished print is very marked when the paper has been subjected to moisture (as you will see from the sample prints which I have passed round), the image having a flat, muddy, sunk-in appearance.

One of the first things which demands consideration is the sort of negative required to yield the best results. This is very much a matter of opinion, but it may be taken for granted that any good negative having a normal exposure, with clear gradations from high lights to shadows, with harmonious half-tones, will give a good print. I myself always develop to get a thin plucky negative, which generally yields a good print if over-exposure has been avoided. Very thin negatives do not give good results on the H.H. paper, but the new C.C. paper is said to be specially suited for such negatives.

Having got a suitable negative, the next step is to prepare the printing frame for its reception. It is well to be on the safe side, and thoroughly dry both frame and back with the padding (especially the latter) before a fire. The negative is placed in the frame in the usual way with the paper in contact, and, in order that the paper may be protected from moisture whilst in the frame, it is usual to keep in contact with the back of the paper some waterproof material, generally vulcanised indiarubber. There is, however, no necessity to go to the expense of procuring this, as a sheet of oiled paper, such as is used in offices for the copying of letters, is, in my opinion, far more efficient for the purpose, besides being much cheaper. Several thicknesses of paper are put behind this, and the back put on and secured in the usual way.

As the paper is much more sensitive to light than the ordinary P.O.P., this operation should be conducted in subdued light, as the effect of short exposures to light does not appear until after development.

The paper before exposure to light, as you will see, is of a pale lemon-yellow colour. As printing proceeds, the shadows begin to appear, gradually gaining in strength and depth. First showing a tint of bluish or greenish-grey, printing will proceed until these dark portions are a decided blue-grey, and, if the negative is a very plucky one, with a wide range of contrasts, it may be necessary to carry the printing on until the shadows are of a slight orange-brown. By this time the other portions of the print will have advanced, according to the quality and gradation of the negative, the high lights being just visible. If the shadows become bronzed before the high lights are visible, it may safely be taken that the negative is too harsh, and, if not under-exposed, should be reduced.

It will be seen from this description that the process is not, strictly speaking, a print-out one—that is to say, the image does not print out to completion in the frame.

Printing takes about two-thirds the time P.O.P. would have taken to give a print ready for the toning bath. If printing be carried beyond this stage, no apparent change takes place, as no over-printing is seen until the print is developed. For this reason printing is the only vital point throughout the process, and it is only by practice that the beginner will acquire the small amount of skill necessary to judge when printing should be stopped. This is, however, not a difficult matter, for, after a few trials, the necessary skill will be acquired.

Several types of actinometers have been invented to aid the beginner, but they are really of very little service unless several prints are required off one negative, when they are of use, inasmuch as they help to ensure that all the prints shall be printed to the same depth. It is advisable to develop the prints as soon as possible after being removed from the printing frame, although, if care is taken to preserve the prints in a dry condition, they may be kept for a few days before being developed. This, in my opinion, has a deleterious effect on the finished print, which seems to lack the fresh brilliancy of the print that has been developed soon after printing. As the developing process is such a simple and brief

operation, there is no reason why the prints should be kept any length of time after printing.

The developer consists of a solution of neutral oxalate of potash, and is best made up as a stock solution of—

Oxalate of potash	16 ounces.
Water	54 „

For use make up in a separate bottle a solution of one part stock solution and two parts water. This used solution should be kept separate from the stock solution, and, in consequence of its dilution, will deteriorate after a certain number of prints have been developed. When defective development is observed, it should be thrown away, and a new one made up from the stock.

If the bath is slightly alkaline, it gives warmer tones than when acid, in which case the tones are colder. The bath should not be too alkaline, but just sufficient to blue-red litmus paper. Carbonate of soda or potash should be used for this purpose, and, if the bath is required acid, oxalic acid should be added. I may mention that the developer which I am using to-night is almost neutral.

The prints are developed by first floating face downward on the developer, when they may be turned up so that progress of development may be observed, which should be stopped as soon as the desired result is obtained by passing the print into an acid clearing bath made up of—

Pure hydrochloric acid	1 part.
Water	60 parts.

The pure acid should be used, and not the commercial. The prints should remain face downward in this bath for five minutes, after which they should be put into a second bath for about ten minutes, and finally into a third bath for about fifteen minutes. The above is the time recommended by the makers as necessary for the clearing of the prints, but I have never left them in longer than ten or fifteen minutes altogether, and I have never found the prints suffer any ill by curtailing the time. The last bath should be quite colourless when the prints are removed.

The prints should be washed in running water for half an hour or three-quarters, after which they may be dried between blotting-paper, or allowed to dry in the open.

The Company prepare a special developing salt known as the D salt. A stock solution is made up of—

D salt	½ pound.
Water	50 ounces.
For use of stock solution	1 part.
Water	1 „

They claim that this developer gives colder tones than the oxalate developer, and also more half-tone.

For intense black tones use—

Stock solution	2 parts.
Water	1 part.

Development usually takes about thirty seconds or more. The developer is used cold, that is, to say, at a temperature of from 60° to 100° Fahr. If the developer is used colder, it tends to give coarse granular prints, and, if it is too hot, it tends to give brown, muddy tones when correct exposure has been given, although under-exposed prints may often be saved by heating the bath.

The question may be asked as to the relative costs of printing on P.O.P. and on platinum.

Taking P.O.P. quarter-plate size, we have thirty-six sheets, 1*s.*; 3 gr. gold chlorids at 2*s.* for 15 gr., say 5*d.*; sulphocyanide, 45 gr., ½*d.*; hypo, ½*d.* Total cost, 1*s.* 6*d.* for thirty-six prints, or ·5*d.* per print. Against this we have for the platinotype process twenty-four sheets, 1*s.* 6*d.*; oxalate bath, ½*d.*; acid bath, ½*d.* Total cost 1*s.* 7*d.* for twenty-four prints = ·79*d.* per print. Therefore platinum is fifty-eight per cent. dearer than P.O.P., or, in other words, 100 platinum prints cost as much as 158 prints on P.O.P.

These figures may appear at first sight rather appalling to the thrifty mind, but then we have not taken into our calculation the expensive language used, and that still more expensive item in all photographic operations, viz., failures! The very words silver and gold spell failure and stumbling-block for the beginner, and I do not suppose that among our oldest workers there is one who will be bold enough to say that he has overcome all the defects of the silver process, and can always rely on the results as permanent and lasting. The platinotype process is simplicity itself, and the results are certain and permanent.

I think that if two beginners were set to work at the beginning of the season, one working silver and the other platinum, it would be found at the end of the season that the cost per print (after throwing away failures) would be as much, if not more, for the silver print than for the platinum print, and perhaps the worker in platinum might have a medal in his possession, whereas the worker in silver would probably have earned a certificate (for West Green).

I know of no better method of comparing the costs of the two processes than the above.

Local Development.—The developing process which I have just demonstrated is the simplest for the beginner, but greater latitude is put into the hands of the more advanced worker by the "Brush method" of development, either the oxalate developer or the Company's special developer may be applied by brush. The prints themselves will bear a considerable amount of brushing without injury. Developing is, however, much easier if the developer is mixed with glycerine; the surface of the paper is better preserved, and the image penetrates less.

A stock solution is made up of—

Oxalate of potash, 1 ounce	1 part.
Water, 3 ounces 3 drachms	„
Glycerine, pure	„

For use, mix 1 part of stock solution with an equal volume of water.

The salts with which the paper is coated are almost insoluble in pure glycerine, and the addition of glycerine to the developer slows its action. This property places considerable power into the hands of the worker, as an over-printed portion of the print, such as the sky, may be retarded by the proper application of glycerine and developer, until the other portions of the image have gained full strength. W. H. Tittensor.

EXHIBITION OF THE BELGIAN PHOTOGRAPHIC ASSOCIATION.

The Musée Moderne at Brussels, which is the scene of the second Exhibition organized by the Association Belge de Photographie, just opened, is a most suitable building for the display of all kinds of pictures. It has evidently been built strictly for this purpose, and therefore, in the way of lighting and convenience of hanging, is all that can be desired.

The Salon principle here obtains, viz., a selection committee and no entry fees or awards, but at Brussels each accepted exhibitor receives the medal of the Society as commemorative of that acceptance and the occasion. From details supplied by the Secretary (M. Vanderkindere), it appears that some 2300 pictures were sent in by 225 exhibitors, the work of the jury reducing these to 500 frames by 182 exhibitors. These were divided up as follows:—

Great Britain.—Mr. & Mrs. Anckorn (Arbroath), Ernest R. Ashton (Tunbridge Wells), Harold Baker (Birmingham), E. Evelyn Barrow (London), Chas. S. Baynton (Birmingham), Harold E. Brightman (Bristol), John Carpenter (London), C. Casstine (Swanley), Chaffin & Sons (Taunton), S. Chapman (Swansea), H. J. Claque (Sheffield), Chas. E. Cowper (Sunderland), W. Dawes (Plumstead), Fred. Dean (Burgess Hill), Donald Dove (Glasgow), A. R. Dresser (Bexley), Thos. E. Ellis (Woolwich), Henry Everett (London), John H. Gear (London), H. J. Godbold (Hastings), Miss L. Halliday (London), Arthur Hands (Leytonstone), Geo. L. Hankins (London), Martin J. Harding (Shrewsbury), G. J. Harris (London), W. M. Harrison (Falmouth), Miss L. Harvey (Liverpool), Hedges & Sons (Lytham), E. Cecil Hertslet (London), Alf. J. Jeffreys (Chelmsford), Chas. Job (Lindfield), Johnson Bros. (Henley), J. F. Lloyd (Liverpool), Reg. B. Lodge (Enfield), E. Lumsden Brown (Edinburgh), Fred. Marsh (Henley), Sam. G. Mason (Birmingham), W. Mawer (London), Wm. Norrie (Fraserburgh), Chas. H. Oakden (London), Henry W. H. Palmer (Forest Hill), Hubert Palmer (Great Yarmouth), Charles A. Russell (London), Chas. Smerdon Roe (Cambridge), Ernest Spenser (New Southgate), G. V. Taylor (Plumstead), G. E. Thompson (Liverpool), Henry Tonkin (Penzance), Miss M. Watson (Florence), R. S. Webster (Edinburgh), Mrs. Jeanie Welford (London), Walter D. Welford (London), J. C. Warburg (London), Alfred Werner (Dublin), West & Son (Southsea), F. Whaley (Doncaster). The total number, with a few who have sent lantern slides only, of 59.

Belgium.—V. Bennert (Brussels), Eugene Boule (Ghent), J. Bouvart (Antwerp), Leon Bovier (Brussels), Alb. Canfyn (Ghent), Jos. Casier (Ghent), H. Colon (Antwerp), Désiré de Clercq (Grammont), Louis de Clercq (Ghent), Albert de Gryse (Courtrai), Ad. de Kemmeter (Ghent), Ed. de Meuler (Brussels), Ad. de Penaranda (Brussels), C. de Wit (Antwerp), Edwin Ganz (Brussels), Charles Gaspar (Arlon), A. Gautier (Saint Pierre), Georges Hina (Brussels), Raymond Geruzel (Brussels), Georges Glorieux (Brussels), R. Ickx (Courtrai), A. Jossart (Fosses-la-Ville), Alphonse Leirens (Ghent), Hyacinthe Lentz (Tournai), Leon Noel (Antwerp), Alberic Lunden (Antwerp), Jos. Maes (Antwerp), Ferdinand Michel (Namur), Leonard Misonne (Gilly), Georges Oury (Liège), Commandant L. Pavard (Louvain), Henri Peltzer (Brussels), Chas. Pullemans (Brussels), R. Rousseau (Jambes), A. Rubot (Brussels), Edm. Sacré (Ghent), Victor Selb (Antwerp), J'Serstevens (Uccle), Gust van Bellingen (Antwerp), Désiré Vanden Hove (Ghent), Marcel Vanderkindere (Uccle), Jules van Grinderbeek (Louvain), Charles van Loo (Ghent), Gust van Raveslyn (Turnhout), Hermann Wiener (Brussels), Jules Willenz (Antwerp), Zeyen (Liège). The Belgian Association has its various sections at Antwerp, Brussels, Ghent, Liège, Louvain, and Namur, and it will be seen, that in this total of forty-six accepted exhibitors, the three first towns largely predominate.

France.—Baillot D'Estivaux de Willemoune (Chateauroux), Paul Bergon (Paris), Madame Binder Mesbro (Paris), Paul Bourgeois (Paris), Augustin Boutique (Douai), Victor Bracq (Boulogne), Maurice Bremard (Paris), M. Bucquel (Paris), Auguste Charrel (Le Vesinel), Ferd. Coste (Lacanche), Louis Courtois (Auby), Arth. da Cunbia (Paris), Jules Des-

champs (Boulogne), Pierre Dubreuil (Lille), Oscar Dumont (Lille), René Le Beque (Paris), Emile Leprêtre (Lille), Paul Leroux (Paris), Henri Magron (Caen), L. Mairesse (Lille), Carle de Mazibourg (Paris), Joseph Millon (Boulogne), Lucien Pasquier (Maubeuge), Robt. Pauli (Lille), E. Piaget (Lyon), M. F. R. Pineiro (Paris), J. Quentin (Arraz), Claudius Tocranchal (Paris), Jules Turlotte (Lille), Ernest Vrac (Caen). Total, 31.

Austria.—Oscar Berl (Vienna), Carl Florianschulz (Vienna), Hermann Heydenhauss (Vienna), Ernest de Juhos (Vienna), Helmer Koch (Vienna), Joh. Langer (Vienna), Leopold Rosenberg (Vienna), Baron Alb. de Rothschild (Vienna), Philipp von Schœller (Vienna), Adolph. Stenicka (Teplitz), Severin Warteresicwicz (Vienna). Total, 11.

America.—John E. Dumont (Rochester), A. L. Eidemiller (St. Paul), Chas. E. Fairman (Washington), Eugene Lee Ferguson (Washington), W. A. Fraser (New York), Hinsdale Smith (Springfield), H. A. Latimer (Boston), Herbert A. North (Philadelphia), W. B. Post (New York), Dexter Thurber (Washington), Henry Troll (Philadelphia), Floyd Vail (New York), Geo. L. Wilson (Jersey). Total, thirteen.

Germany.—Fritz V. Abercron (Hamburg), Gust Haeyn Wilms (Bielefeld), Max Junsnickel (Rathenow), Wilhelm Klementz (Frankfort), Carl Leibrock (Saarbrucken), H. Rosenthal (Guben), Otto Scharf (Crefeld), Edward Zinsel (Darmstadt Hessen). Total, eight.

Holland.—B. Albach (Amsterdam), Ignace Bispinck (Amsterdam), Jan de Grijs (Amsterdam), Baron de Pallandt Rozenbeuvel (Arnheim), H. E. Scheidius (Arnheim), Georges Singling (Amsterdam), J. H. B. Wylmans (Middelsourg). Total, seven.

Italy.—Horace Consoli (Giarre, Sicily), Giorgio Goselli (Venice), Comte Louis Primoli (Rome). Total, three.

Switzerland.—Fred Boissonnas (Geneva), Alfred Sules (Bâla), A. Wicky (Berne). Total, three.

Russia.—De Golovallchewsky (Baloum), G. Raieff (Kislovoosk), A. Sohat (St. Petersburg). Total, three.

Portugal.—Joachim Basto (Porto).

To reduce 2300 frames down to 500 shows that the jury dealt unsparingly with the pictures. At the same time, the large number of exhibitors shows a slight tendency to selecting at least one exhibit, even if nine were rejected, and we should say that this has been done to some extent. Certainly to bring the average quality of the work to some extent up to our own Salon, at least another 250 frames would have to be rejected.

The general feature of the English work is that of landscape and seascape, with a tendency towards *genre* in that from our American *confrères*. Amongst the Continental workers, however, there is a good deal of *genre* and portraiture. The English and American work occupying one entire room gives an easy opportunity of comparison with the general run of Continental work; but, as there is no sort of division in the remaining two rooms, it is difficult to follow this any further so as to compare Belgium with France, Holland, &c.

The hanging has been carefully done, the general arrangements providing every convenience, and there is, moreover, a complete absence of skying or flooring. As a rule, the English frames run smaller, and certainly show, as a whole, greater taste in mount and frame. Green plush, blue serge, enamelled cream and gold, and other obtrusive mounts, mar many of the Continental frames. This is made worse also by over-elaboration of frame, and, in some cases, by a howling wilderness of margin. We think the photographic visitors to the Exhibition will learn from the English exhibit that it is better to trust to the merit of the print than to attempt any bolstering up in the mount or frame, which catches the eye and draws the attention away from what should be the centre point of attraction. Some of the exhibits might well be described as a white enamel and gold frame with elegant plush mount containing a photograph.

The catalogue is a very handsome production. The names, alphabetically arranged, are printed in red, with the descriptive matter in black; a rough surface and raw-edge paper is used, and the cover has the inscriptions impressed and not printed. It is, in fact, quite a creditable result for both the Association and the printer. The titles of the pictures are, in most cases, translated into French; but in some cases, where exact translation is difficult or impossible, the original English, Dutch, &c. is quoted. Another point is, that not only are the names given alphabetically, but the numbers follow consecutively, so that, as far as reference to the catalogue goes, it is perfectly easy to follow the frames on the wall.

Space will not allow of a detailed criticism of the exhibits, and a few general notes must suffice. Prominent amongst the English exhibitors are Ernest R. Ashton (Scenes in Cairo), E. Evelyn Barron (Seascape), Harold Baker and Charles H. Oakden (Architecture), Chaffin & Sons (Large Portraiture), John H. Gear, Thomas E. Ellis, W. Dawes, John Carpenter, G. L. Hankins, R. S. Webster, E. Cecil Hertslet, A. J. Jeffreys, Charles Job, and others, with the class of landscape that is now so much in vogue in England, West & Son (Marine), Reginald B. Lodge (Bird Studies), Fred Marsh (Large Flashlight Pictures). We have seen better work by A. R. Dresser, and there are a few other English exhibits barely worth hanging.

The tendency of the American work is towards *genre* and figures, and there are good examples by A. L. Eidemiller, Charles E. Fairman, John E. Dumont, Eugene Lee Ferguson, Dexter Thurber, and Floyd Vail. W. B. Post is largely represented, and by some very excellent work; but he, together with George L. Wilms, sticks closely to landscape.

Amongst the Continental workers, the most striking pictures are those of B. Albach (Holland), Fred. Boissonnas (France), A. Bouligne (France), Leon Bovier (Belgium), Victor Bracq (France), Louis Courtois (France), Désiré De Clercq (Belgium), Ad. de Kemmeter (Belgium), Giorgio Goselli (Italy), Hermann Heydenhauss (Austria), R. Ickx (Belgium), Leon Noel (Belgium), L. Maviesse (France), Carle de Mazibourg (France), Georges Millon (France), who seems to follow the Millet school, Georges Owry (Belgium), Commandant Pavard (Belgium), R. Rousseau (Belgium), Edm. Sacré (Belgium), Victor Selb (Belgium), Claudius Touranchet (France), Gust Van Bellinger (Belgium), Ernest Vrac (France), — Zeyen (Belgium), and, to single out two or three of those endeavouring to strike out into new paths for themselves, we should mention Messrs. Bovier and Sacré.

The display of slides sent in for exhibition took place, on Sunday last, at the rooms of the Association, in the Palais du Midi. From England there were Architectural and Marine, by Bertram C. Wickisson, London; Flowers and Marine, by J. T. Field, London; Street Scenes, by Walter D. Welford, London; and Various, by Algernon Brooker, Hastings. Amongst the more striking exhibits from abroad were the Figure Studies of Edward Ganz, Brussels; the Flower Studies of William A. Fraser, New York; Marine Studies of J. Latimer, Boston; and *Genre* Subjects of Leonard Mizonne, of Gilly, Belgium.

In the evening a private dinner took place at the Hotel de Vienne, when the officials, the jury of admission, and Mr. and Mrs. Welford were present—an enjoyable but informal evening. Mr. Welford was presented with a special souvenir medal of the Society, for his efforts in England on its behalf.

For the souvenir album of reproductions, works by the following have been chosen: England—Geo. Hankins, W. M. Harrison, Chas. Job, Chas. Smerdon Roe, Geo. E. Thompson, R. S. Webster, Mrs. Welford, Alf. Werner. America—J. E. Dumont, H. A. Latimer, Eugene L. Ferguson, Geo. L. Wilms.

NOTES FROM THE WEST OF SCOTLAND.

Judging from the spirit, in fact almost enthusiasm, with which our local photographic societies have entered into the idea of holding conversaziones in lieu of lantern demonstrations for their popular nights, it would appear as if, in future at least, so far as the West of Scotland is concerned, there will be much fewer lantern exhibitions.

The recent social meeting of the West of Scotland Amateur Society was quite a big thing, and must have cost a considerable sum to organize; but, then, this popular Society is flourishing, both as regards numbers of members and its funds.

The Paisley Exhibition, which has been open for the last month, has just been brought to a close. Among other good things provided by the Council was a grand display of animal studies by Mr. Charles Reid, of Wishaw, who attended personally on the occasion, when about two hundred of his best pictures were thrown upon the screen.

With the fine weather experienced during the holidays, there has been quite a flutter among amateur workers, who are mere *en évidence* this year than ever. Hand cameras are seen everywhere, and some of these are of considerable size. The modest quarter-plate, so universally adopted as the handiest size for what was originally designated detective cameras, is fast being supplanted by the half-plate, for many of the best workers in the district have found out that a heavy camera is easier held steady than a feather-weight one.

Among the new forms of hand cameras just placed on the market is one made by Messrs. Vérel, of the Albion Albumenising Company. The main feature of this excellent arrangement consists in the camera folding up in such a manner that all cases or covers, and other adjuncts, so often seen in such instruments, are entirely dispensed with by an ingenious device, the dark slides are stowed away inside the camera, and, when such is folded up, no one would ever suspect that a camera was being carried, its appearance resembling a lady's bonnet box of small dimensions.

Mr. William Riddell, late of Riddle & Rae, has started business on his own account, and has just issued a very comprehensive catalogue which contains some up-to-date novelties.

The X rays craze is dying down among photographers generally in this district.

Mr. William Carmichael, of the chemical department of Messrs. George Mason & Co., has recently been giving some very interesting demonstrations on the making of acetylene gas.

PHOTOGRAPHIC EXHIBITION AT BEVERLEY.

The Beverley Photographic and Sketching Society held its third annual Exhibition in the Assembly Rooms on Easter Monday, the opening ceremony being performed by the Rev. Dr. Nolloth, who was formally introduced by Captain Forrest, one of the Vice-Presidents of the Society.

The exhibits were effectively staged in tiers on stands draped with art muslin, and the large room was rendered the more picturesque by the introduction of a number of choice palms and plants in bloom, together

with a quantity of bunting kindly lent by Mr. C. J. Newbald. The specimens exhibited included excellent examples of the photographic, painting, and kindred arts, and in the competitive section numerous silver and bronze medals were awarded as prizes. The entries were very large, and many of the competitors were of high standing, having gained distinction both at home and foreign exhibitions. The side rooms were set apart for lantern exhibitions of the prize slides, given at intervals, and for an interesting demonstration on "Photo-ceramics," given by Mr. W. Ethelbert Henry, C.E., of London. One attraction which had been announced, a lecture and demonstration of the Röntgen X rays, had unfortunately to be postponed, in consequence of the inability of Mr. T. W. Ireland, who was to have given it, being unable to procure certain of the requisite apparatus in time. The Society, however, intend to hold it at an early date.

The following were the awards:—

OPEN CLASSES.

Landscape, Seascape, and Architecture.—Silver medal, W. J. Warren, Leeds; extra silver medal, George L. Wilms, Jersey, U.S.A.; bronze medal, W. Smedley Aston, Birmingham; extra ditto, Charles Rumbold, Great Yarmouth; certificate, Floyd Vail, New York, U.S.A.

Portraits, Figure Study.—Silver medal, T. Lee Symes, Tyldesley, Lancashire; extra ditto, Fred Marsh, Henley-on-Thames; bronze medal, E. Lee Ferguson, Washington, U.S.A.; certificate, Mrs. W. D. Welford, London, and J. H. Coath, Liskeard.

Hand-camera Work.—Silver medal, W. Thomas, London; bronze medal, C. F. Inston, Liverpool.

Enlargements.—Silver medal, Albert Durn, Wooton-under-Edge; certificate, J. B. Briggs, Lancaster.

New Photography.—Silver medal, T. E. Freshwater, London; bronze medal, A. Campion, Royal Indian Engineering College, Staines.

Lantern Slides (set of six).—Silver medal, G. Hankins, London; bronze medal, E. R. Bull, London; extra bronze medal, J. H. Gear, London; certificate, John Ward, Erdington, Warwickshire.

Paintings, Drawings, and Sketches.—Mr. Tempest, Beverley; Mr. T. L. Flather, Scarborough; Miss Beesie Cross, Hull; Miss E. R. Marshall, Reverley; Miss Ethel Beaumont, Beverley.

MEMBERS' CLASSES.

Landscape, &c.—1. Maurice J. Stephenson, Beverley; 2. C. Goulding, F.C.O., Beverley; 3. G. Dawson, Beverley.

Portraits.—1. Mrs. W. Thompson, Molescroft; 2. G. F. Duck, Bishop Burton; 3. G. Dawson.

Excursion Work.—Bronze medal, C. Goulding.

Enlargements.—Silver medal, H. J. Mann, Beverley; bronze medal, T. Tanfield.

Instantaneous.—Bronze medal, C. Goulding; 2. R. Railston Brown, C. E. Bridlington; 3. J. Kinsley, Bridlington Quay.

Lantern Slides (set of six).—1. A. E. Hobson; 2. C. Goulding; 3. R. Railston Brown; 4. Thomas Tanfield.

The Inquirer.

*** *In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* JOURNAL *useful and instructive.*

PHOTOGRAPHY IN BARBADOES.—"BARBADOES" asks: "Could you give the names of some of the best photographers in Barbadoes? Do you think there is any opening for an operator of ability? and what salaries are given? Is there any chance of opening up on own account, or is it overrun? What is the distance, and which is the best route?"—Perhaps some travelled reader can supply the desired information.

CHLOROPHYLL.—W. H. G. writes: "Allow me to thank Mr. F. E. Ives for his reply (p. 208) to my previous query. It seems I have been unnecessarily worrying, not only myself but others, in a vain search after 'blue myrtle' which nobody recognised, while I have bushels of the article I want, but under another name, in my own garden. Now that the common names of the 'blue myrtle' are placed on record—Vinca minor, or the common periwinkle—many others like myself may be saved a lot of trouble. I want to use the chlorophyll chiefly for collodion films, but do I understand Mr. Ives to mean that it is of no use in conjunction with gelatine, however applied? Of course, I know it will not dissolve so well in the emulsion, but may it not be effective when applied as a bath?"

CARBON PRINTING.—J. C. writes: "I have recently taken up carbon printing, which seems to me a process specially adapted to the wants of the amateur. Although I have mastered the technical difficulties of development and transfer, I cannot say that I am by any means satisfied with the general results I obtain. My negatives are of ordinary average density and give good brilliant prints with the gelatine or collodion print-out papers, especially the latter, but in carbon they are either weak and flat or heavy, and free from sparkle according to the depth to which the printing is carried. I have tried all depths of printing, in fact from the same negative I have made different exposures each with a different 'tint' of the actinometer, and the results have been as I have stated, all unsatisfactory and only varying in degree of exposure. Does the process require a special kind of negative? Any help you can give me I shall greatly appreciate."

Our Editorial Table.

THE PHOTOGRAPHIC REFERENCE BOOK.

Compiled by W. A. Watts, M.A. London: Iliffe & Son, 3, Bride-street, E.C.

THIS is a work of nearly 300 closely printed pages, mainly compiled from those columns of our contemporary, *Photography*, which are devoted to the eliciting of information by means of questions and answers. The information has been classified into twenty chapters, thus facilitating reference. For example, we have treated, under separate sections, "cameras and apparatus connected therewith," "lenses (stops and optical matters)" "process work" "varnishes and cements," &c., &c. The matter has been very judiciously selected, and the photographer will pick up many a useful hint from the book, which teems with valuable information and suggestions on photographic technique, partly new, but chiefly the outcome of past experience and experiment.

THE KOH-I-NOOR RETOUCHING PENCILS.

L. & C. Hardtmuth, 12, Golden-lane.

A SET of the Koh-i-noor retouching pencils has been submitted to us by Messrs. Hardtmuth. These pencils, which are made of compressed lead, have a useful range of softness and hardness for retouching work, for which purpose, according to the evidence of expert retouchers, they are well adapted.

RÖNTGEN PHOTOGRAPHS.

By Professors Waymouth Reed & J. P. Kuenen. Dundee: Valentine & Sons.

THIS is a series of well-executed collotype reproductions, by Messrs. Valentine, from negatives made by the gentlemen named, who are attached to the University College, Dundee. The pictures, of their kind, are very good, and the subjects are somewhat uncommon: a star fish, a flounder, a frog, tortoises, a cat's tail, and a baboon's hand being among those of which the osseous structures have been laid bare by the remorseless Röntgen rays.

THE CATHCART DRY PLATES.

F. W. Vérel & Co., Cathcart, near Glasgow.

FROM Messrs. F. W. Vérel & Co., Cathcart, near Glasgow, we have received, for trial, samples of their plates, the Cathcart "ordinary," and "special rapid." The former is a plate of medium rapidity, and is a useful, clean, and easily developable plate for all-round studio and outdoor work. The "special rapid" is extremely sensitive and fine in the grain, and, for very quick exposures, will be found to yield excellent results. Judging by the samples, the Vérel plates are prepared with scrupulous care, and are therefore well qualified to hold their own in the estimation of photographers.

Fitch's Special Extra Rapid Films.

E. H. Fitch & Co., Seldon House, Fulwood's-rents.

During the holidays we tried some of Mr. Fitch's latest make of celluloid films, and, as heretofore, found them beautifully clean and regular, and of a degree of rapidity which should satisfy all reasonable exigencies in the way of speed. The size we used was the once popular $7\frac{1}{2} \times 5$, and the films remained perfectly flat in an ordinary dark slide. Mr. Fitch has certainly mastered the art of turning out a celluloid film upon which, in the way of technical excellence, it would be difficult to improve.

Encyclopëdie der Photographie, Vols. XVIII. and XIX.

Wilhelm Knapp, Halle a/S.

These two volumes are valuable additions to this comprehensive work on photography. No. XVIII., entitled *Der Silberdruck auf Salzpapier*, by Baron von Hübl, treats of the preparation of the various kinds of salted papers, and the processes involved in their use for the production of photographs. Albumenised, gelatinised, resinised, and other varieties of salted paper are described, and those who still see beauty in a silver print (and are there not many?) will find in these pages reliable information for making, keeping, and toning. At the close of the second part, the author gives a short but appreciative expression of opinion on the value of salted papers compared with other printing surfaces, in the following terms: They are not of universal use, but they will be utilised where their advantages recommend them. They may be used instead of gelatino-bromide paper, because of their safety in printing and simplicity; instead of matt collodion paper, because of greater ease of preparation; and, lastly, instead of platinotype, where the negatives are unsuitable, when brown or blue-toned prints are required, and to avoid uncertainty in printing. Volume XIX., *Die Anwendung der Photographie zu Militärischen Zwecken*, by Premier-lieutenant Kiesling, treats of the many applications of photography in military affairs. It contains chapters on the reproduction of maps, plans, &c., photogrammetry, balloon, kite, and rocket photography, microscopic reductions, the photographing of bullets in flight, and other subjects. There is also an account of the experimental use of photography in the Prussian army before and during the Franco-Prussian War, and its subsequent use by other nations for military surveys, &c. The work contains a number of illustrations, and is a good reference book for those interested in the subject.

Die Chromo-lithographie.

By Friederick Hesse. Halle a/S.: Wilhelm Knapp.

We have received the first number of this work, which promises to give a comprehensive account of chromo-lithography in its several branches, with practical directions. The number describes the principles upon which lithography and chromo-lithography are based, and gives an account of materials, tools, &c. There are a number of illustrations in explanation of the text, and the work will contain fifteen specimens of chromo-lithography, two of which are issued with the first part.

Catalogue Received.

Andrew Riddell, 139, West George-street, Glasgow.—Mr. Riddell's catalogue is in some respects novel in its arrangement. The first few pages are devoted to illustrations of some ninety odd hand cameras, and are followed by descriptions of them. Studio and field cameras are also described in the same section, which is printed on pink paper. Lenses, photographic stationery and sundries have each separate sections, printed on distinctively coloured papers. By these and other means, Mr. Riddell's catalogue, which is very complete, is made extremely easy of reference—a feature that should be highly appreciated.

News and Notes.

On Saturdays, April 18 and 25, at 7.30 p.m., Mr. E. J. Wall will deliver two lectures on *Colour Photography as applied to Printing* at the Photographic Process School, Central Art Department of the Technical Education Board, 6, Bolt-court, Fleet-street, E.C.

Our Japanese contemporary the *Shashin Sowa*, in its last number, was troubled by the failure of its printers to render a half-tone block successfully. It thus apologises:—"Dur illustration, showing difference the two brands of P. O. P. did not came out well as we have seen in proof, so we shall renew the insertion of the same by comming number."

Royal Photographic Society.—Photo-mechanical Meeting, Tuesday, April 21, at eight p.m. *Photo-mechanical Notes of Historical Interest*, by T. Bolas, F.I.C., F.C.S.

Queensland Amateur Photographic Society, Brisbane.—The following office-bearers have been elected for the ensuing year, viz.:—*President:* Mr. D. Mactaggart.—*Vice-Presidents:* Miss Stennett and Mr. M. E. Brookes.—*Council:* Dr. Thomson, Dr. Wheller, Mr. C. J. Pound, and Mr. D. R. Eden.—*Treasurer:* Mr. W. Connolly.—*Hon. Secretary:* Mr. J. J. Campbell.

Walworth Junior Postal Camera Club.—The Hon. Secretary and Treasurer, P. C. Cornford, 36, Inville-road, Walworth, London, S.E., writes: "There are now two vacancies for membership in the above Club, and the mention of the fact through the columns of your valuable paper will be deemed a favour. I shall be pleased to send all particulars on receipt of a post card."

New American Photographic Publications.—The *Practical Process Worker* is the title of a new monthly publication devoted to process work; it is published by the Scovill & Adams Company, New York.—The first number of the *Professional Photographer* has been sent us. It aims to be a practical journal for professional workers, and is published by the Nesbitt Publishing Company, Buffalo, N.Y.

Acetylene.—A German writer remarks that, for the production of a light of one normal candle power, 0·6 litre of acetylene is required per hour if a proper burner is used. For the same lighting power with ordinary gas burners ten to twelve litres of coal gas are consumed. There are, however, various qualities possessed by acetylene which are of a somewhat dangerous nature, namely, its action upon copper or copper alloys. For instance, with copper alloys it forms a brownish substance which is very highly explosive; therefore such metals are unsuitable for use within the conduits or for glow bodies if acetylene is employed as a lighting material. Iron is of neutral conduct towards acetylene. It is well known that a certain mixture of acetylene and air is explosive, the highest explosive power being reached in a mixture of one part of the gas to twelve parts of air. Also, like all carburetted hydrogen gases, acetylene is poisonous, though not so poisonous as ordinary coal gas in even lesser quantities. The danger of liquefied acetylene gas is considerable, for, if it is stored in a steel cylinder at six to seven hundred pounds' pressure, in the event of a fire breaking out in a building containing it, it would be decomposed, forming carbon and hydrogen; the latter would have a pressure of 20,000 pounds per square inch, which would burst the cylinder and cause widespread damage. Even a slight leak in the cylinder would be very dangerous, for three or four per cent. of the gas in the air would cause a violently explosive mixture. Acetylene gas can also be exploded by fulminate of mercury, and the gas also makes explosive compounds in coming in contact with copper.

Central Art Department, Bolt-court, Fleet-street, E.C. (Guild and Technical School of the National Society of Litho-Artists, Designers, and Engravers, under the joint control of the Technical Education Board L.C.C. and the National Society of Litho-Artists, &c. Spring Session, 1896).—The Schools reopened on Monday, April 13. The Sketching Class will be held, as usual, on Mondays, from 7 to 10 p.m. The Committee wish it to be thoroughly understood that members of the Life, Antique, and Design Classes can join the Sketching Class without extra fee. The arrangements for this class are in the hands of the students, and the Art Director would be glad to meet intending members to consider the subjects for the ensuing session, and to form a strong Committee. Life Class, Tuesdays and Thursdays, 7.30 to 10 p.m. Antique, Wednesdays and Fridays, from 7 to 10 p.m. Study and Practice of Design, Fridays, from 7.30 to 10 p.m. Process Drawing, Tuesdays and Thursdays, 7.30 to 10 p.m. Perspective Class, Mondays, 7.30 to 9.30 p.m. Study and Practice of Litho Drawing, Tuesdays and Thursdays, 7 to 10 p.m. Study of Aquatint Engraving, as applied to Letterpress Printing, Tuesdays, from 7.30 to 10 p.m. Photo Process School, Session 1895-96. The Second Term commenced on Monday, April 13. These Classes meet as follows:—Mondays, 7 to 8.30 p.m., Line Etching on Zinc; Tone Etching on Zinc, Copper, and Brass. The Class is limited to Twelve Students; should there be a greater number of entries, an extra class will be held from 8.30 to 9.45. Tuesdays, 7. to 8.15 p.m., Photo-lithography in Line and Half-tone. Tuesdays, 8.15 to 9.45, Half-tone Negative-making. Wednesdays, 7 to 8.15 p.m., Line and Half-tone Negative-making. An additional class will be held from 8.15 to 9.45 if there are more than twelve entries. The Secretary will be in attendance every evening from 7.30 to 9.30, and will gladly furnish any further information.

Patent News.

The following applications for Patents were made between March 25 and April 8, 1896:—

Film Cameras.—No. 6489. "Improvements in Film-changing Photographic Cameras." Complete specification. C. Beck, W. Beck, jun., and J. T. Clarke.

Projection Apparatus.—No. 6503. "Improvements in the Mechanism of Chrono-photographic, Kinetoscopic, and Lantern Projection Apparatus." G. W. de Bedts.

Cameras.—No. 6582. "Improvements in Photographic Cameras." L. J. R. Holst.

Kinetoscope.—No. 6604.—"Improvements in Apparatus for Exhibiting Photographs to obtain the appearance of Objects in Motion." A. G. Bessemer, jun.

The Parastudio.—No. 6608. "The Parastudio for controlling the Light in connexion with Photography, as being applicable to Outdoor Portraiture." W. Watson.

PHOTOGRAPHIC PRINTS.—No. 6651. "Improvements in Chemical Compositions to be used for Preparing the Surface of suitable Material for Photographic Prints." Complete specification. P. E. SCHOENFELDER and E. KEHLE.

REPRODUCING DRAWINGS.—No. 6657. "Improvements in Photographic Apparatus for Reproducing Drawings, Engravings, and the like." E. POTHIER.

COPYING ENGRAVINGS.—No. 6662. "Mode of and Means or Apparatus for Producing Photographic Negatives from Engravings and the like." F. H. WOOD.

PRESSURE FRAMES.—No. 6766. "Improvements in Pressure Frames for Photographic or other Purposes." L. A. MARION, H. GUIBOUT, G. BISHOP, F. BISHOP, and J. P. KIRK.

CAMERAS.—No. 6791. "Improvements in Hand and other Photographic Cameras." W. J. LANCASTER.

CAMERAS.—No. 6805. "Improvements in Cameras for Photographic Purposes." G. H. BANISTER.

PHOTOGRAPH FRAMES.—No. 6907. "A Frame for Photographs made of Perforated Cardboard, with or without a Design for Needlework printed on it." E. GRIFFITHS.

PRINTING FRAMES.—No. 6977. "Improvements in Photographic Printing Frames." W. TYLAR.

MOUNTS.—No. 7141. "Improvements in Picture Frames, Photographic Mounts, and the like." N. MYRSTEDT.

PHOTOGRAPHIC APPARATUS.—No. 7172. "Improvements in Photographic Apparatus." F. TOWNSEND.

AUTOMATIC PHOTOGRAPHS.—No. 7271. "An Apparatus for Automatic Production of Photographs." Complete specification. H. F. C. SASSE.

SHUTTERS.—No. 7309. "Certain Improvements in Photographic Shutters." E. UNDERWOOD.

SPRING LENS CAP.—No. 7314. "The Spring Lens Cap (Photographic)." E. HODGSON and E. HODGSON.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

April.	Name of Society.	Subject.
20	Camera Club	*The Coming Total Solar Eclipse.* Captain E. H. Hills, R.E.
20	Richmond	Open Evening.
21	Bournemouth	Discussion on Exhibition.
21	Gospel Oak	Exhibition of Prize Slides.
21	Hackney	Prize Slides.
21	Leeds Photo. Society	Discussion on Developers. Opened by Dr. Thresh.
21	North Surrey	Annual General Meeting.
21	Royal Photographic Society	*Photo-mechanical Notes of Historical Interest.* T. Bolas, F.I.C., F.C.S.
22	Croydon Camera Club	*An Introduction to Photo-stereography.* G. W. Watson.
23	Bradford	Open Night.
23	Camera Club	Sixth Annual General Meeting.
23	Ireland	Lantern Slides by Members.
23	Leeds Camera Club	Annual Meeting and Election of Officers.
23	Leigh	Business Meeting.
23	Liverpool Amateur	Explanatory Show of Photographic Novelties. James A. Sinclair.
23	London and Provincial	*Micro-photographic Reductions.* G. W. Atkins.
23	Woolwich Photo. Society	*The Chemistry of Every-day Photography.* W. H. Dawson.
24	West London	*Mountain Scenery.* Leslie Selby.
25	Borough Polytechnic	Excursion: Blackheath and Chislehurst.
25	Camera Club	Last day for sending in Pictures intended for Annual Exhibition.
25	Leytonstone	Excursion: Richmond Park. Leader, B. Harwood.

ROYAL PHOTOGRAPHIC SOCIETY.

APRIL 14,—Ordinary Meeting,—Captain W. de W. Abney, C.B., F.R.S., in the chair.

Seven new members were elected, and eight candidates were nominated. It was announced that the Isle of Thanet Photographic Society and the Leeds Camera Club had been admitted to affiliation.

The ASSISTANT SECRETARY (Mr. R. Child Bayley) read a note on a method of ascertaining

THE MELTING POINT OF GELATINE SOLUTIONS.

He said that any one who had had to ascertain the temperature at which various solutions of gelatine passed from the solid to the liquid state knew that it was by no means easy to do so with any great amount of accuracy by the means usually employed—a test tube, thermometer, and water bath—while the time occupied in making a number of such determinations was considerable. Having to examine a number of jellies with a view to ascertain the influence of alum and other hardening agents upon them, he had devised a simple apparatus which he exhibited, and which, after repeated use, had been found reliable. It consisted of a water bath capable of being heated by a spirit lamp or Bunsen burner without the hot air or products of combustion reaching its largest side; along this side, at a distance of one inch from the top, was ruled a straight line, and one or more thermometers were so supported in the bath that their bulbs were as close as possible to the position of the line on the metal, but inside the bath. To use the apparatus, the vessel was laid upon its side, and, by means of paper tubes, the jellies to be tested were allowed to solidify in discs, with the bottom edge of each just upon the line on the tank. When the gelatine was set, the paper could be removed, and the tank stood upright and filled with water, and all that was then necessary was to heat the water and note the temperature at which the discs of jelly commenced to slide down the side of the bath.

Professor W. C. ROBERTS-AUSTEN, C.B., F.R.S., then described a method of

RECORDING HIGH TEMPERATURES BY PHOTOGRAPHIC MEANS.

He first referred to the fact that for measuring temperatures exceeding about 400° it was necessary to resort to methods other than the ordinary mercurial thermometer, and mentioned two such methods which could be readily adopted. The electrical resistance of a platinum wire could be ascertained, and the increase of its resistance caused by heating would be a measure of temperature; or wires of two dissimilar metals could be twisted into a junction, which, being heated, would behave as a battery and generate electricity, the strength of the current so generated being again a measure of temperature. The method which he had found best suited for the purpose, was then illustrated by means of a series of drawings. The free ends of a thermo-junction, formed of wires of platinum alloyed with iridium or rhodium, were attached to a galvanometer enclosed in a camera. From a source of light external to the camera a ray was reflected from a mirror through the lens on to a movable mirror of the galvanometer, another ray being similarly thrown on to a fixed mirror, the light from which could be periodically interrupted. Both rays passed through fine vertical and horizontal slits, and thence on to a photographic plate contained in a carrier capable of being moved upwards by means of a driving or water clock. When the thermo-junction was heated it became a battery, and the strength of the current generated was a measure of the temperature to which it was raised. The result was that, if both spots of light started fair, the one from the fixed mirror would remain in a definite position, while the one from the movable mirror of the galvanometer would register the temperature to which the thermo-junction was heated. It is difficult in this brief report, and without the use of diagrams, to adequately describe Professor Roberts-Austen's method, by which he said it was possible, at a temperature of 1000 degrees, to obtain a record trustworthy to a tenth of a degree. He proceeded to show a series of slides illustrating the industrial application of the apparatus in connexion with the ascertaining of the temperature of the air supplied to blast furnaces; and, as an example of the service which photography had thus rendered to industry, he stated that in some cases it had rendered possible a reduction in the consumption of coal at the rate of one hundredweight per ton. With regard to investigations generally, it was known that, if a salt was placed at the bottom of a cylinder of water, the salt would gradually diffuse upwards until it was uniformly distributed through the water, and precisely the same thing occurred with metals. Experiments had proved that, if a heavy metal was placed at the bottom of a molten, mass the heavy metal would be diffused up, against gravity, throughout the mass; and it was of extreme importance to metallurgists to be able to measure the temperature at which the diffusion took place, and photography had rendered it possible to do this with great accuracy. For all his measurements he referred finally to the air thermometer as an arbiter.

After some remarks by the EARL OF CRAWFORD and Mr. HEARSON,

Professor ROBERTS-AUSTEN, at the suggestion of the Chairman, referred to the diffusion of metals in the cold, and mentioned some curious instances of solids "walking into" one another. For example, if a diamond was placed on a piece of iron, and the whole heated to about 800°, the diamond would gradually "walk into" the iron; similarly, if a cylinder of pure lead was fused to a plate of gold, and the whole heated to 90° or 100° below the point at which the lead would melt, in about a month an appreciable quantity of gold would be found at the top of the lead. Further, if cylinders of lead and gold were placed accurately together in a vacuum tube, and heated only to 40°, in a day they would unite so firmly that a strain equal to one-third of the breaking strain of lead would be required to sever them.

The CHAIRMAN referred, in complimentary terms, to the utility of the methods adopted by Professor Roberts-Austen, to whom a cordial vote of thanks was then passed, and the meeting closed.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

APRIL 9,—Mr. T. E. Freshwater in the chair.

DEFINITION OF LENSES.

The HON. SECRETARY showed a print of a $7\frac{1}{2} \times 5$ negative, taken with one of the new Ross-Zeiss convertible anastigmats used as a single lens. The focus of the single combination was $11\frac{1}{2}$ inches, and an exposure of one second was given with full aperture, *f*-12·5. In answer to a question, he said the two combinations of the lens were not of the same foci, being 9 inches and $11\frac{1}{2}$ inches respectively, and forming together a lens of $5\frac{1}{4}$ inches focus. Until the introduction of this lens, he thought there was no single lens which at full aperture would give such fine definition as that shown in the print.

The opinion of those present was that it was of very fine quality. The full aperture was equal to the open tube.

The HON. SECRETARY said that one advantage was that all flare was done away with, there being no stop used.

Mr. ATKINS showed what the old form of Ross's rapid symmetrical would do in the way of copying black-and-white subjects, and passed round several examples. The lens was of $8\frac{1}{2}$ inches focus.

HALATION.

The HON. SECRETARY raised the question as to which gave the most halation, exposing through the glass plate or in the ordinary way.

Mr. A. MACKIE said presumably there would be less in exposing through the plate.

Mr. R. P. DRAGE referred to a suggested method for the prevention of halation, which was to place a piece of thin silvered glass in optical contact with the back of the plate with the aid of glycerine. He also mentioned an old experiment in which the emulsion was coated on a silvered plate.

A discussion as to the practical utility of this method ensued, it being

mentioned that the oblique rays would be reflected on to a different part of the film than that through which they entered, the effect being less noticeable the nearer to the centre of the plate.

The HON. SECRETARY believed that the use of films got rid of a lot of halation, and said that, of three exposures recently made on one subject with a backed and an unbacked plate and a film, only the unbacked plate showed halation.

DEVELOPMENT.

A discussion took place on the question of protracted development.

Mr. HARVEY had tried watering the developer, but generally got fog through long development, although he was in the habit of covering up the plate. He asked whether, under the following circumstances, intensification would be practicable. In developing a plate he had accidentally allowed twice the proper amount of pyro, and consequently got a fearfully dense negative. This he had reduced, but prolonging it too much had reached the opposite extreme. He had tried printing under green glass, but with no better success.

It was thought that intensification might improve it, and it was recommended to try bromide paper as likely to give a better result than gelatine, which was the paper used.

A short discussion followed on the relative permanence of albumen and gelatino-chloride papers.

PHOTOGRAPHIC CLUB.

APRIL 8,—Mr. Frank Haes in the chair.

Mr. J. R. WILLIAMS asked the members' opinion upon a recent experience he had had in

PHOTOGRAPHING MICROSCOPIC SUBJECTS.

He found that for certain subjects, viz., more or less opaque objects upon a clear ground, there was a large degree of solarisation or halation, and that the outlines of the image became blurred. He had tried the experiment of substituting for the ordinary caramel backing a piece of silvered glass, brought into optical contact with the sensitive plate by a film of glycerine. He obtained by this means results in which there appeared to be little or no halation or blurring, and he asked for some explanation of it.

Various possible explanations were suggested.

Mr. MACKIE thought possibly that, owing to the extra thickness of glass behind the plate, the light became reflected from the silver backing in so diffused a manner as to be less noticeable, in the same way as a flare spot in a lens is modified by altering the position of the diaphragm, although the flare is not actually done away with.

Mr. WILLIAMS said, in reply to further questions, that he preferred the caramel backing, and had only adopted the other method for experimental purposes.

A member referred to the recent show of lantern slides by Mr. Evans, and said it was noticeable that this gentleman had succeeded in avoiding all the defects generally due to halation, although he had worked both plates and films without backing upon most difficult subjects. Mr. Evans's explanation at the time was that he gave sufficient exposure, and always developed his plates in a tentative manner. In addition to this, he always made the photographs at a time when the incidence of the light was suitable.

Mr. FOXLEE drew attention to the fact that Mr. Evans also used a very long-focus lens, and it was pointed out that this might assist in minimising the spreading action of the light through the film.

Mr. MACKIE pointed out out that in the recent Watkins's competition, which had been held under the auspices of the Club, it was quite clear, from the results, that halation was influenced by development to a certain extent. He instanced the case of negatives where all the effects of halation which were likely to occur were overcome by the use of a very highly restrained developer. He also said that it was notorious that some men could not make a negative without the effect of halation being noticeable, whereas others with similar makes of plates and similar subjects contrived, by manipulating their exposure and method of development, to avoid the defect altogether. Halation was not due to any one particular cause, but to an aggregation of causes.

Brixton and Clapham Camera Club.—March 31.—Messrs. Milne & Co., of Balham, demonstrated the working of their

VENUS ARTISTIC PRINTING PAPER.

This paper somewhat resembles Mezzotype, but is prepared in an entirely different way, and is said to give prints which are really permanent. It is supplied in four grades, from a smooth matt to a rough Whatman's surface, and the working is very similar to that for ordinary silver papers. Vigorous negatives give the best results, and printing should be done in a strong light to the depth wanted in the finished picture. The prints are soaked in water to get rid of free silver, and then toned in the combined bath specially prepared by the Company, or in any gold or platinum bath suitable for silver papers. Toning takes from six to ten minutes, a good range of tones—sepias, browns, purples, blacks, &c., being got according to the bath used and time taken in toning. The prints are next rinsed in water and fixed in:—Hypo, 2 ounces; borax, ½ ounce; water, 20 ounces; and afterwards washed for about two hours. Drying can be done by heat, the paper containing no gelatine. The working of the paper, as shown by Mr. Milne, was very easy and certain, and the rendering of detail, good tones, and purity of the whites were specially noticed and indicate the paper to be a very useful one.

Bromley Camera Club.—On April 10 a lecture was given by Dr. CHARTERS-WHITE on

PHOTO-MICROGRAPHY

at the School of Science and Art, Tweedy-road, Bromley. The members of the Club turned up in full muster with their friends, nearly 200 being present altogether, including a great many of the local doctors. The lecture, which was illustrated by the lecturer's own slides, including, among others, anatomical subjects, parts of insects, and crystals, proved to be most interesting and highly instructive, and was greatly appreciated by the audience.

Camera Club.—The members of the Camera Club, like all other mortals who are not under the necessity of keeping their noses to the grindstone, have mostly been away holiday-making, and consequently the place has been almost empty save for the visitors who have been attracted by Mr. Henry Stevens's remarkable exhibition of pictures, which still occupies the walls of the large room. But of evening meetings there have been few, the last one of importance before Easter being devoted to a paper by Major Lysaght and Mr. Henry E. Davis, which attracted a good many interested listeners. Mr. DAVIS was the spokesman, and described, with much felicity and an occasional little joke, a series of peregrinations which he and his gallant comrade had made among the beautiful environs of London. This paper was an object-lesson to those on pleasure bent, who in a few days would be running across to the Continent, or to far-off resorts, in search of beauties which can be had in plenty within half an hour's rail of the metropolis. But not only were the views of topographical interest, for some of them were highly artistic, and the section devoted to the details of hop-picking were instructive as well. On April 2 Captain Wilson Barker was down for a paper entitled,

CLOUD FORMS AND TROPICAL WEATHER,

but so many members had by this time fled from town that it was deemed advisable to postpone the reading of it until the coming Conference, when a large audience may with confidence be counted upon. It was a pity that so few members assembled last week to hear Mr. A. Mallock's discourse concerning the advantages of being able by the camera to secure a true vertical line. Some may have thought that there was no necessity to raise such a question, because rectilinear, symmetrical, and other lenses of the same type are constructed with the express object of reproducing vertical and other straight lines with the utmost exactitude; but that is not quite what Mr. Mallock intended to convey when he gave to his interesting paper the somewhat alarming title,

ON A PHOTOGRAPHIC METHOD OF FINDING A TRUE VERTICAL LINE, &c.

His real object was to point out how the camera can be made into a most vigilant detector of any line in a building which ought to be vertical, but which, from any cause, has deviated from the perpendicular position which the architect and builder intended it to have. There are hundreds of such buildings, some of which have bent down under the weight of their own top hamper, some owing to faulty materials, and a larger class to the giving way of weak foundations. The leaning tower of Pisa is not the only example of the "slantingdicular" style of architecture; it has representatives in every capital, from the stately Parthenon to the ugly little dissenting chapel at Little Peddlington. Such deviations from the vertical may be great or small, and they are sometimes so small that they cannot be readily detected, nor can it be ascertained, without much calculation and the help of a theodolite and scaffolding, how far the error extends. There are few architects or builders who care to go to much expense to show that the stones which they have put together are wanting in verticality. It is like expecting a man to buy a guillotine with which to operate upon his own unfortunate neck; but when both architect and builder have long returned to the dust—dust which is possibly a component part of mortar for newer erections—it often becomes necessary, as a matter of precaution, to find out whether a building is straight or leaning. Mr. Mallock's process for doing this with the camera is really a new application of photography, upon which he may be congratulated. He uses a quarter-plate camera, and it is placed on a baseboard, having room in front for a small tray or tank filled with glycerine and water. This gives him an artificial horizon, and in this miniature sea every line of a building which it is desired to test is reflected. In a negative so obtained it is easy to ascertain if his verticals are right or wrong; but first a datum line must be obtained, from which measurements can be made by means of a micrometer. This is provided by a single fibre of natural silk, just as it comes from the cocoon, which is stretched across the plate and fastened with wax at each end. The rest of the operation is a simple question of exact measurement. Mr. Malloch showed a number of interesting examples, and also explained how errors due to aberrations of the lens, inequality of the glass plate, &c., could be detected and remedied. This new method of conducting by simple means an operation which used to be both tedious and costly is likely to have many applications.

Croydon Camera Club.—The meeting on Wednesday, April 8, was devoted to the consideration of

HALATION IN DRY PLATES, AND ITS CURE.

The PRESIDENT, in introducing the lecturer, stated that halation is very much more often present than is suspected; a high speed, *i.e.*, coarse-grained film, produces general veiling of the shadows through the granular particles radiating light on to the back of the glass, which becomes reflected and strikes in varying degrees all over the back of the film. Mr. J. T. SANDELL then read his paper, which dealt with both halation and latitude, in the course of which he explained with much clearness—not to say special knowledge—the variations in chemical and physical properties which different emulsions are liable to, and how these variations made fast plates more subject to halation than are slow ones. But the most rapid plate possible will always be the favourite, hence some means of counteracting the extreme tendency to halation in such plates is called for. Mr. Sandell reviewed and criticised various remedies, as the sienna and caramel backing, the potassic permanganate substratum, the ammonium picrate staining of the film, and then proceeded to explain his own invention, namely, the multiple-coated plate. In these two or three sensitive emulsions are superimposed. The top one is of the highest possible speed, the lower ones are of ordinary slow speed. It hence follows that, whilst the top film will register an image with very short exposure, the fine grain and opacity to actinic light of the lower film prevents light radiated from the coarse-grained top film from falling on the back of the gloss and producing the defect known as halation. Mr. Sandell also explained how his device ensured a much larger amount of latitude as regards error in exposure, and referred to two prints of negatives shown, in which, while one of the latter had an exposure of one minute, the other was exposed for fourteen hours. Mr. Sandell subsequently developed three plates which he had exposed for two, four, and six minutes respectively, using a weak metol solution; the

above were successfully developed. Using a diluted developer as aforesaid, the time is about twice or thrice that usual for completion of negative, twenty to thirty minutes being the normal time needful with the developer recommended.

Hackney Photographic Society.—April 7, Mr. W. A. Ilensler presiding.—Excursion matters were discussed. It was announced that the first outing for the especial benefit of beginners would take place on Saturday, the 18th inst. Party to meet at Snaresbrook for River Roding, by the first train after 2 p.m.

South London Photographic Society.—April 8, Annual Meeting, the President (Mr. F. W. Edwards) in the chair. Twelve new members were elected, and six more nominated. The HON. SECRETARY presented his report, showing that the Society had maintained its position, and that a considerable number of interesting and instructive papers had been read at the bimonthly meetings during the year. The Seventh Annual Exhibition had been held, and was very successful. The number of foreign competitors was more than double that on former occasions, and one of the Judges' awards was to an American competitor. The excursions had been better attended, and two three days' outings had been carried out, when a large number of members were present. There had been a good number of hirings of the camera sets (12×10 and whole-plate), and also the club lantern. Some useful additions to the library had been made, and two original enlargements (*Ginx's Baby* and *Happy Days*), and also two original prints by the late O. G. Rejlander had been presented to the Society. The election of officers resulted as follows:—*President:* Mr. F. W. Edwards, F.R.P.S.—*Vice-Presidents:* Messrs. S. W. Gardner, Maurice Howell, W. Rice, F.E.I.S., W. F. Slater, Dr. T. G. Munyard.—*Committee:* Messrs. M. Boxall, W. C. Boyce, C. F. Dickinson, H. Esler, A. Fellows, F. W. Grigg, B. Lyon, G. A. Maull, W. D. Welford.—*Curator:* Mr. G. H. Moss.—*Hon. Lanternist:* Mr. J. T. French.—*Hon. Treasurer:* Mr. A. E. Whitby.—*Hon. Secretary:* Mr. Charles H. Oakden, 30, Henslowe-road, East Dulwich, S.E.—*Hon. Assistant and Excursion Secretary:* Mr. A. E. Allen, 27, Princes-square, Kennington, S.E.—*Delegates to the Affiliation of Photographic Societies:* Messrs. Charles H. Oakden and W. D. Welford.

Tooting Camera Club.—April 7.—M. LUBOSHEZ, of the Eastman's Photographic Materials Company, Limited, delivered a lecture upon

THE MANIPULATION OF BROMIDE PAPERS.

The lecturer also treated the audience to some very lucid ideas upon the subject of lighting in portraiture. At the finish, several members owned to the articles of their photographic creed being severely shaken, especially regarding the effects of bromide salts in development, and the permanency of bromide prints toned to an artistic brown by M. Luboshez' method, the effect of which is undoubtedly obtained by sulphur toning.

Aintree Photographic Society.—April 10.—The room was well filled by friends and visitors, who responded to the invitation of hearing a lecture on

GLASGOW AND THE VALE OF CLYDE,

illustrated by about 180 slides, kindly lent by the Glasgow and West of Scotland Photographic Association. The Vice-President, Mr. W. B. Hellon, undertook the descriptive part. Many of the slides called forth loud praise. A series of outings have been arranged for the summer months, the first to take place on Saturday afternoon, April 18, to Thornton, Crosby, Crosby Hall and Park (by permission of Colonel Blundell), Ince, Blundell, and Sefton.

Liverpool Amateur Photographic Association.—April 9.—Mr. PAUL LANGE gave a demonstration of the production of

ENLARGED NEGATIVES

from smaller-sized plates, and exhibited about a dozen fine examples of his skill in this direction, the enlargements being 15×12 inches, mostly from 5×4 inches hand-camera shots, and gave minute details of his method of procedure. Te lecture was listened to with interest by a good number of members, and it is hoped many will take advantage of the means placed at their disposal to produce a good show of pictures at the next annual competition.

Moseley and District Photographic Society.—April 10, Captain Davidson in the chair.—Mr. WALTER GRIFFITHS gave a paper, entitled

MISCELLANEOUS.

The lecturer suggested the title would cover anything he would have to say or could be said, so he plunged then into the mysteries of plate-making as a first subject. He set a piece of gelatine to soak in H_2O. Having dissolved some potassium bromide in hot water and some silver nitrate, the bromide solution was added to the gelatine, which, being reheated, the gelatine dissolved. The silver nitrate was then added slowly, when the matter immediately assumed a milky appearance, and, of course, was sensitive to light. From the adding of the silver nitrate downwards, the emulsion must be made in the dark or red room, although the lecturer did it in gaslight to show the members more plainly, so the emulsion would be useless. The lecturer did no more now, but explained how the emulsion should be washed and boiled, and the plate should be coated, levelled, and dried, when they would be in a fit state for exposure. Then you have a dry plate, good or bad, according to the emulsifying and the absence of fog, &c. The lecturer then took his audience through the mysteries of isochromatism, explaining how the difference between the visual and actinic differences of the spectrum were more evenly balanced. He then called attention to lenses, showing the crown and flint glasses of uncemented lenses; how they fitted together perfectly, and the exactness of the curvatures (the lenses were of his own manufacture). He went on to explain the action of long and short-focus lenses, advising a long-focus lens, as giving more pleasing perspective, and warning against short-focus when possible, as giving strained perspective. Having explained the rising front, swing back and front, the lecture came to a close.

Dundee and East of Scotland Photographic Association.—The seventh monthly meeting of the Dundee and East of Scotland Photographic Association for the session 1895-6 was held in Lamb's Hotel, Dundee, on Thursday, the 9th inst., Mr. A. Stewart in the chair. Three new members, nominated at last meeting, were admitted, and five additional names were submitted for consideration a month hence. It was explained that the lease of the old Chess Club-rooms as the rooms of the Association was now prepared, and only awaited signature. Mr. W. H. TITTENSOR gave a demonstration of platinotype development, including the cold-bath process, and showing also a development with glycerine and a brush. This paper appears on page 248.

Correspondence.

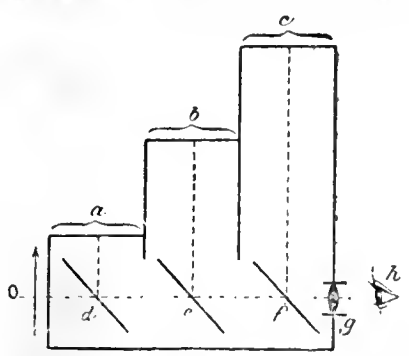
PHOTO-CHROMOSCOPES.

To the EDITORS.

GENTLEMEN,—Without in any way wishing to reopen the discussion on this subject closed by you in your last issue, will you allow me to point out that Mr. Ives has omitted from his notes all mention of Zink's photopoly-chromoscope, a diagram of which was published by you in your issue for July 26, 1895, as an illustration to my paper before last year's Convention.

The following passage from *Die Darstellung der Natürlichen Farben durch Photographie*, by Hermann Krone, fixes the date of its construction, and this will be interesting in future and complete Mr. Ives's useful notes:—

"In the early part of 1893 Carl Zink, photographer of Gotha, without knowing anything of Ives's photo- or helio-chromoscope, constructed an apparatus which can be used for the same purpose as the latter, which he called the photopoly-chromoscope, and which, on account of the great simplicity of its arrangement with greater lightness, appears to be able to



accomplish the same as Ives's apparatus. In the Exhibition of the twenty-third Convention of the Deutschen Photographenvereins in Frankfurt a/M., in August 1894, Zink publicly showed the first specimen of this, his photopoly-chromoscope, and, after it had been tested, a silver medal was awarded to it by the jury of the Convention."

The photo-chromoscope of Ives here referred to is the old form, U. S. Patent, No. 475,084, May 17, 1892, which, of course, antedates Zink's machine.—I am, yours, &c.

E. J. WALL.

ASSISTANTS AND THEIR GRIEVANCES.

To the EDITORS.

GENTLEMEN,—You published in your issue of April 3 a very able article, giving some good advice to assistants seeking employment.

I sincerely hope it will be of some service to the many assistants now out of employment.

Cannot some competent writers on the staff of the JOURNAL take up the brief on behalf of the poor sweated assistant? I am sure, from the letters which have appeared in the JOURNAL during the last twelve months, their grievances need remedying, and well deserve serious attention. Take the sweating which goes on in one large firm of cheap photographers. On Good Friday and all Bank Holidays operators slave away from nine till five, with no time for meals, taking from sixty to seventy sittere; then, I am told, have to stop to do the developing, or be bullied. I am aware the firm is well known to London assistants, and is boycotted by them. The result is, this firm are always changing (assistants either give notice or take French leave)—are compelled to rely on assistants "green" from the country. I am sure if a member of your staff could interview the hands employed by this firm he would be able to publish some painful revelations as to the treatment of the assistants. They are, I am told, afraid to write to the JOURNAL in case of being "spotted," and so they work year in and year out, having to put up with this harsh treatment. So bad is the treatment becoming, it is nothing, so I am told, for assistants to go out to tea and not return any more.

Obviously it is necessary something more should be heard on the subject.

I was hoping to see an article in this week's JOURNAL on the assistants' grievances.

I think the time has arrived when something should be done to redress their grievances.

Is it too much to ask Mr. Randall to try another shot at forming an Assistants' Union, and thus bring these sweating firms to book.—I am, yours, &c., A North Wales Operator.

[We are always happy to throw open our columns to operators and assistants who may desire to discuss their position and prospects, with the view of improving them, and a perusal of our pages for years past will show that we have never neglected an opportunity of endeavouring to help them in their legitimate aspirations and grievances. We ask, as we have many times asked before, why do not photographic operators, assistants, and *employés* generally combine to form a union for mutual support and assistance?—Eds.]

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

To the Editors.

Gentlemen,—It may be a matter of interest to some of your readers to know that instruction meetings are held monthly by the above Society, when elementary photographic subjects are treated in a manner specially adapted to the requirements of beginners and junior workers.

Gentlemen taking up the study of photography are always welcome to attend, and I shall be pleased to render information to inquirers.—I am, yours, &c., W. Taylor, *Hon. Sec.*

38, *Palace-road, Hornsey, N., April* 3, 1896.

Answers to Correspondents.

*** *All matters intended for the text portion of this* Journal, *including queries, must be addressed to* "The Editors, The British Journal of Photography," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* Henry Greenwood & Co., 2, *York-street, Covent Garden, London.*

Received:—Marion & Co.; Edgar Scamell; "Elphin;" H. A. Aylward; T. J. Evans. These, and others received too late, in our next.

Cut P.O.P.—P. and D. Thanks for your letter.

Address.—E. G. We are unable to supply the address desired. We do not find the name of the firm in any of the foreign journals we have.

Spurge's Sensitometer.—C. S. says: "I should be much obliged if you could inform me where I can procure Spurge's sensitometer."—Write Mr. J. B. Spurge, care of Mr. Clarkson, Bartlett's-buildings, Holborn.

Developer.—Anxious. Some workers prefer pyro ammonia, and others pyro soda. With some brands of plates the one developer is said to give better results than the other. It is, however, much a matter of opinion. Both are good.

Out of Focus.—C. Walkden. If the lens gives perfectly sharp negatives with one camera and not with the other, it is pretty clear that the focussing screen and dark slides of the latter are not in accurate register. The remedy is obvious.

Enlarging.—S. W. Carbon tissue is too slow for enlarging upon direct, even if the limellght with a mixed jet be employed. With a powerful electric light under favourable conditions, enlargements can be made direct, but the exposure is then long.

Reversed Negatives.—T. Leach. The most general way of taking reversed negatives is by using either a prism or a mirror. Some, we know, take them through the glass; that is, instead of putting the plate in the camera film side next the lens, the glass side occupies that position. The disadvantage of this method is that any scratches on the back of the glass, or air bubbles in it, are reproduced in the negative.

Patenting an Invention.—Patent. 1. Write to the Comptroller of the Patent Office, Southampton-buildings, London, W.C., and you will obtain the necessary form to fill up. 2. A drawing will suffice. 3. Provisional protection will cost you 1*l.*, and will last for nine months. As you appear to have very little experience of such matters, we should recommend you to place yourself in the hands of a respectable patent agent.

Addresses of Exhibitors Wanted.—M. Lavington. We believe that a later edition of the book you name has been published. Failing that, a copy of our Almanac will give you the names of the manufacturing firms, and the section devoted to photographic societies supplies a ready means for the distribution of your circulars, which would reach exhibitors through the medium of the secretaries of their societies.

Nitrate of Silver.—The green colour of the crystals is due to the presence of copper. That is always the case when the nitrate is made from old silver plate, unless means are taken to get rid of the copper. You would have found it more economical to have sold the silver to the refiner than to have converted it into the nitrate. You can now only sell the salt to the refiner, as no one would purchase it for photographic purposes.

Right to Photograph.—Visitor. Although the owner has a perfect right to make a charge for permission to photograph the ruins when taken from within the grounds, he has no such right when they are photographed from the public roadway. The caretaker exceeded his rights in attempting to prevent you from taking the picture from the outside. We are glad you persisted in the face of the threatened summons, which was mere "bluff."

Head Rests.—Davis & Sons ask: "Can you inform us the address of the successor to the business of the late Mr. Emmerson, of Briggate, Leeds, who was a maker of a specially light head rest?"—In reply: Our correspondents probably allude to Mr. G. Day, 11, Edward-street, Lady-lane, Leeds.

Agreement.—R. W. H. If the three years' agreement expires on May 1, you can leave without giving your employer any notice at all, unless there is a clause in it that notice is to be given. It will, however, be more courteous to tell your employer of your intention, particularly as he has an impression you will remain in his service.

Residues.—H. Casey. It is no use whatever saving the old developer from dry plates, or that from bromide paper, as neither of them contains silver. The old fixing solutions are worth saving, but they will contain much less silver than you used to get from the albumenised paper which you sensitised yourself. Nothing is better than the sulphide of potassium for throwing down the silvar.

Studio.—R. Will's. You will not improve on the design. If, however, you can get it two or three feet longer, you will find it more convenient at times in working. Decidedly, have iron sash bars in preference to wooden ones, as the studio will be a brick building. By all means submit the plans to the Council's surveyor before commencing to build, not that we think that there will be any objection to the structure, but it may avoid any after-quibbling.

Toning Collodio-chloride Prints.—G. P. writes: "Would you be so kind as to tell me Paget's formula for toning collodio-chloride prints, as I don't know it? I always prepare my own paper, as I have done for many years, and toned it with the sulphocyanide bath, but I can't get the right tone for matt paper."—In reply: See this Journal for September 13, where very full working instructions are given. The toning formula is simply: Ammonium sulphocyanide, 30 grains; gold chloride, 2 grains; water, 16 ounces.

Blisters.—Amateur in Trouble writes: "I have to-day, for the first time, used the sensitised paper, and I find it blisters very much. I first washed the prints in several changes of water, then toned in carbonate of soda, 10 grains; gold, 1 grain; water, not distilled, 10 ounces; then washed in two changes of water; then I put them into a fixing bath of hypo, same strength as for plates, five parts to one; then washed in two changes of water, when the blistering came, but only two out of the four. What is the reason, do you think? Why are not the other two blistered? Was it because I left them for a while to soak after fixing, or was the fixing bath too strong? If you could help me in this, I would be much obliged."—Some papers are more prone to blistering than others. There is nothing in the formula used to cause it, presuming that in the fixing bath our correspondent means one part of hyposulphite of soda to five of water. Blistering may be avoided, with blistering paper, by immersing the prints, before they are washed for toning, in methylated spirit for a few minutes, then washing and toning as usual.

Renovating Silver Bath.—Henry Ryan writes: "I should be glad if you would tell me the easiest, at the same time the best, method of making new silver baths from old ones. I generally dilute to twice its bulk, filter, and boil down till all the nitrate is fused, then make up to strength again, neutralise, and sun for some time. I use a fairly good-sized bath—about 160 ounces; but, after working about forty $8\frac{1}{2} \times 6\frac{1}{2}$ size plates, it gets over-iodised, and I have to keep always boiling it down. Would the addition of barium nitrate do any good, or is there anything else you could recommend? Last week a piece of putty somehow got into a bath, and has discoloured it very much. Filtering is not of any use. Would you kindly tell me how to eliminate it?"—Putty is certainly not a good addition to the silver bath for wet collodion, and it may have quite ruined it. Our correspondent seems to have begun at the wrong end at renovating the bath. It should first be diluted, then neutralised, and afterwards sunned, filtered, and then boiled down and fused. The silver, then dissolved, will make a new bath, which may or may not require acidifying. This treatment will, doubtless, restore the "putty" bath.

Stereoscopy, Radiography, &c.—Photophil writes: "You are so generous to your cloud of interrogators that I am tempted again to seek your aid, "Bis dat qui cito dat," though I feel I am almost abusing your indulgence. However, it will probably cost your serene encyclopædicity little to reply to one or more of the ensuing queries: I. In what place in Europe should I get most cheaply a quantity of the coloured spectacles required for viewing stereoscopic projections made? 2. In what place, also in Europe, should I get a quantity of fairly effective prism glasses for the ordinary stereoscope? In 1 and 2, cheapness would be a *sine-quâ-non*. A job lot might suit. 3. Röntgentype. I should be glad of an impartial (not commercial) approximate estimate of the cost and weight of such electric apparatus as is necessary in order to obtain with ordinary photographic appliances effective Röntgentypes such as would be useful in surgery. I. (*a*) Is a coil necessary? (*b*) Is an accumulator necessary? (*c*) Is a battery necessary in absence of machine electricity? or (*d*) Would a plate machine do, and of what diameter? II. Cannot the coil, the battery, and the plate machine be home-manufactured, leaving only the Crookes' tube to be bought? Price is not so much the difficulty as importation expenses and difficulties. III. Is there a pamphlet as to the *modus operandi* in detail? 4. Was there not given in a back number a cutting board for dividing any plate in halves?"—In reply: I. Messrs. Newton & Co., Fleet-street, supply such spectacles. 2. Probably Messrs. Sharland, Thavies Inn, Messrs. A. E. Staley & Co., 35, Bucklesbury, or Messrs. Clement & Gilmer, Rue de Malte, Paris, would be able to help you. 3. Roughly speaking, an outlay of about 22*l.* would, so far, be necessary. The essentials are coil, battery, and vacuum tube. See article (page 134), which answers your other questions. 4. Have no recollection of it.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1877. Vol. XLIII.—APRIL 24, 1896.

Contents.

EX CATHEDRÂ.

The arrangements for the Leeds meeting of the Photographic Convention, which opens on Monday, July 13 next, are now nearly completed. Mr. Drage, the Hon. Secretary, informs us that the Reception Committee, comprising seventy of the leading residents in the district, headed by the Marquis of Ripon, K.G., have expressed great interest in the forthcoming gathering, and the Executive Committee, presided over by Mr. J. H. Walker, Mr. Herbert Dennison acting as Treasurer, and Mr. Godfrey Bingley, of Thorniehurst, Headingley, Leeds, acting as Local Hon. Secretary, will spare no pains to make the Leeds Convention thoroughly successful. The Mayor of Leeds, the Right Hon. W. L. Jackson, M.P., will receive the members of Convention, in the City Art Gallery, on Monday evening, July 13, at half-past seven.

* * *

Important papers will be read and discussed, and demonstrations of great interest and utility to all photographers will probably be given in the evening throughout the week, for which the commodious rooms of the Leeds Philosophical Society have been engaged, the central position and conveniences of which will be greatly appreciated by all Conventioners. The Excursion arrangements are eminently satisfactory, and the districts surrounding Leeds are perhaps unsurpassed for general interest and picturesqueness. A prominent feature of this year's Convention, and likely to prove a very great attraction, will be an exhibition of a hundred modern pictorial photographs, kindly got together and arranged by the President, Mr. H. P. Robinson, comprising pictures by the leading exhibitors of the last few years. There will be also an exhibition of the newest forms of apparatus in use for photography, and of photographic material and processes by some of the leading trade exhibitors of this country. Everything, therefore, promises well for a successful meeting, and we trust that the efforts of the Executive will be be rewarded by a very large attendance.

* * *

A photograph of lightning, characterised by an unusual feature, has been submitted to us by Mr. W. J. Bishop, who took the negative. The flash presents the usual ribbon-like appearance, but, instead of being, as are most, if not all, such photographs, simply a clear bright line on a dark ground, the flash has both detail and half-tone, imparting to it the effect of being modelled. The suggestion is that what may be regarded as the equivalent of a time exposure was given, hence the detail. The negative, which clearly indicates the phenomena mentioned, well bears enlargement, and the result appears to us so uncommon as to deserve mention.

* * *

A few weeks back we took occasion to congratulate Mr. Thomas Keig, photographer, of Douglas, Isle of Man, on his elevation to the position of first Mayor of that town. We are sorry now to have to record that Mr. Keig did not long live to enjoy his dignified position. He died last week from the effects of cancerous complaints, which resulted in congestion. Mr. Keig was sixty-seven years old.

* * *

We have received the May number of a light and amusing periodical, called *In Town*, the editor of which draws our attention to the fact that, among its many illustrations, not a single photograph is to be found. There are distinct signs in the illustrated press of a reaction against the use of photographs, the objections to which are so well summarised by our ably con-

ducted contemporary, the *Publishers' Circular*, in its last number, that we reproduce some of its remarks on the subject.

* * *

"THERE still remains something to be said on the subject of art and photography in connexion with newspaper and magazine illustrations. To place any ordinary, inartistic photographer in the place of a trained artist, substituting for the imaginative and picturesque the commonplace, unpicturesque, mechanically made photograph, is to degrade the art of illustrating to its lowest level. It is utterly impossible, for instance, with the assistance of ordinary models, to pose living figures satisfactorily in the representation of incidents requiring the expression of passion or the more impressive actions and impulses dealt with in a tale or novel. Yet this practice is becoming more and more common in the illustrating of our magazines and periodicals, as well as books.

* * *

"ARTISTS are frequently, however, largely to blame for the innovation; they themselves so often give us mere portraits of models, as wanting in feeling, expression, and action, as if they were produced by the camera, that editors and publishers think it folly to pay as many guineas for drawings as they would pay shillings for photographs. There are now before the writer some childishly ridiculous specimens of these story photographs, or photograms, as they should really be called. In one the figures are arranged with considerable effect, but they are associated with painted accessories no better than the worst we have seen in a penny stage booth at a country fair. On the other hand, we see no reason why photographic views, landscapes generally, and architectural subjects, street scenes and news incidents of actual occurrence, taken on the spot, together with similar subjects, should not come well within the province of the illustrating photographer. But even here special training and knowledge are required."

* * *

"THE photographers employed on work of this kind should have some practical experience of printing technique, as well as a fair share of artistic taste and feeling—rare faculties, yet many of the wood and copper-engravers possessed them, and more. In a landscape the prevailing sentiment should be caught as well as the actual forms, and this never can be if the operator regards his subject with no more thought or feeling than his lens has. We want, in short, a new class of photographers for such work—operators who not only know the best kind of negative necessary for the production of a photogram block, but the kind of process block which will enable the printer of a paper or magazine to show his most successful work."

* * *

OUR contemporary is conspicuously impartial in its strictures, for it will be observed that, besides the photographers, the artists come in for their share of criticism. The remarks of the *Publishers' Circular* amount virtually to a plea for the combination in one individuality of the artist and the photographer, a desideratum partly met by the growing practices of subjecting process blocks to hand work, and of "preparing" photographs for reproduction. But there is much comfort in the reflection that the spread of pictorial photography through all classes of camera-workers is not insensibly helping forward the movement our contemporary has at heart.

HALATION.

IT was very truly remarked, in the course of the discussion on halation at the Photographic Club a fortnight ago, that this defect in negatives is not due to any one particular cause, but to an aggregation of causes. In spite of this, however, the tendency undoubtedly exists to seek for remedies which shall be universally applicable, and, while the inventor or promoter of any particular plan upholds its infallibility because it answers under one set of conditions, others may totally condemn it because it is useless under entirely different circumstances.

Then, again, it is too commonly the practice to regard all kinds of photographic films as the same in character, and to attempt to apply to each alike the same remedies, whereas, as a matter of fact, almost every kind of film is subject to a different form of the disease, and, consequently, requires an entirely different remedy. Roughly compare, for instance, the effects produced respectively upon thin and transparent, and dense, and comparatively opaque films; if the former, which represent the older dry-collodion films, were subject to halation, how much more so are the thick, almost opaque, gelatine films of to-day. And yet it is expected that the same remedies will answer in both cases, and, in fact, it is assumed that the defect is similar in character in both. How far this is from being the case, a little consideration of the facts will prove.

If the reflection from the back theory were the correct and only explanation of the trouble, then we should certainly find that thin films were hopelessly subject to halation, while the thicker gelatine films were comparatively, if not wholly, free from it; but, as a matter of fact, the very reverse is the case, and, even without going to the extent of comparing collodion and gelatine, it is a well-known fact to old dry-plate workers that some of the denser and least translucent of collodion dry plates were far more liable to halation, or "blurring," as it used to be termed, than others which were absolutely transparent. For instance, the old Hill-Norris plates of three decades ago, which were so clear and transparent that to the modern dry-plate man it would seem impossible to get any result on them at all, were almost entirely free, even under the most aggravated circumstances, from any tendency to halation, while the thick, creamy films of Major Russell's bromised collodion process were peculiarly liable to the defect, although they more nearly approached in character the gelatino-bromide plate.

At the same time it must not be supposed, because a film which is transparent enough to allow the image formed by the lens to pass through it and suffer reflection is not affected by halation, that, therefore, the theory of back reflection fails, nor, in the case of a thicker film that does show halation, that the effect may not be at least partly due to reflected light attacking the under side of the film. The fact is that, while this influence of back reflection is always more or less present, it requires other conditions to work in with it and bring it into prominence. In the case of the transparent collodion film, for instance, it is its very transparency which allows the light to pass freely through it without being arrested, combined with the comparative insensitiveness, that ensures its immunity when such is found to be the condition of affairs; and it is the denser character of the gelatine film which causes it to stop and break up the light rays in their passage, together with its far greater sensitiveness, which renders it infinitely more susceptible to the action of very feeble diffused and reflected light, that the almost opaque modern dry plate owes its peculiar proneness to a defect from which it might be expected to be absolutely free.

It is impossible within the limits of one article to touch upon the different varieties in which the defect of halation is met with, or even to dwell at any great length upon the different forms in which it is met with in collodion and gelatine films respectively. The three chief causes may be set down as: (1) reflection from the back, (2) internal irradiation or reflection from the particles composing the film, and (3) solarisation or excessive action of the light. The two last are indirectly, or it may be directly, affected by the first, which, if not the sole, may therefore be considered as the most important, element to be considered, for, given a certain amount of action from either of the two latter causes, it must obviously be intensified by any additional action of reflected light.

Any method, therefore, which prevents or reduces the reflection from the back of a glass plate must tend to lessen the liability to halation in any form or from whatever cause due. But what are we to say of the reverse method, mentioned at the meeting above referred to as well as at the London and Provincial Association, in which the back surface of the glass plate is converted into a reflecting, instead of an absorbing, one, by silvering? So far as we remember, this idea was first mooted as far back as 1874 by Canon Beechey, the idea being, that, by sending back the transmitted rays in direct lines to act upon the back of the film, the effect was to shorten the exposure without producing any blurring of the original image. But in this calculation the effect of refraction was entirely overlooked; by this influence, and in proportion to the thickness of the glass plate and the distance from the axis of the lens, the image would be doubled, simply because the reflected rays would strike the back of the film in a different place from where they passed through. Under ordinary conditions, such as foliage cutting against a bright sky, or the fine tracery of a window in an interior, the effect would simply be ordinary halation intensified, since the mass of light reflected would obliterate the foliage or tracery. But, if the conditions be reversed, and a number of fine slits in an opaque screen be photographed upon a silvered-glass plate, it will be found that a sharp double image of each slit will be produced, and that, in proportion as the distance from the centre of the plate or the axis of the lens is increased, so will the distance between the two images become greater.

We have before us, as we write, a photograph of a window sash, looking out into a clear sky, taken upon thin silver mirror glass by means of collodion. It is perfectly clear and free from halation, because the exposure was not long enough to cause any tendency in that direction, but it affords an instructive commentary on the value of silvered glass for the prevention of the defect in question. Standing in front of a light, if the plate be examined at an acute angle, it will be found that the direct and reflected images can be made to so overlap that the sash bars are entirely obliterated. Where, then, the utility as a preventive?

PHOTOGRAPHIC SOCIETIES: PAST, PRESENT, AND FUTURE.

THERE are now, in the United Kingdom, something like three hundred photographic societies, and, as others are continually being formed, one cannot help speculating as to what will be the position of many of them a few years hence. As we hear of the formation of new ones, so also we hear of the demise of others. Before speculating on the future it will be as well to look back on the past, and contrast that with the present state of societies. The Royal Photographic Society was established, in 1853, as "The Photographic Society." Soon afterwards other societies were formed in different parts of the Kingdom. Reference to the journals of that early period shows that, as a rule, the meetings were well attended, and the matters brought before them were principally those of a technical character, and original research, for which, as photography was quite in it infancy, there was ample scope. This made the meetings of considerable interest.

Photographers then had to prepare the greater part of the material they used for themselves. There was, of course, no ready-sensitised paper; the user had to sensitise, and at one time even to albumenise, it himself. There were no commercial dry plates; hence the worker had, perforce, to make them by one or other of the bath, or collodion emulsion processes, and their modifications, as then in vogue. Papers, and demonstrations, on the various methods of working were always looked forward to with interest, and the meetings were well attended. It will, however, be noted, when consulting the reports of meetings as given in the journals—say twenty years back—that the interest in the meetings was then flagging somewhat. But, when gelatine photography was introduced, it got a wonderful fillip, and to it must be credited the extraordinary number of societies now in existence. At the time referred to, the chief theme at the meetings was the preparation of gelatine plates, the composition of the emulsion, the method of mixing, cooking, washing, drying, &c. All these formed fruitful topics for investigation and discussion, and much valuable information was brought before the meeting.

After a time, as might be expected, there remained but little original matter to communicate. The manufacture of plates became a settled trade, and few afterwards thought of making their own. Ready-sensitised albumen papers and gelatine, both bromide and chloride, came into the market, hence everything was supplied ready to use, and little interest is now taken by the majority of users in the technics of their production. That is the existing state of affairs.

When a paper is now read, or a demonstration given, it is generally on a method of using some commercial material. It is seldom now that anything like original research in the technics of photography, as in former times, is brought forward, or at least in any of the minor societies. Pabulum for the meetings, is however, frequently provided by manufacturers and dealers by the exhibition of, or demonstration of the use of, their wares, of course for advertising purposes. Many of the meetings are taken up by lectures on a particular district, illustrated by the lantern. But these can scarcely be considered as photographic meetings, as photography is only used as an adjunct to a lecture on, perhaps, architecture or, maybe, archæology, or, indeed, anything else. However, many interesting and entertaining evenings are thus filled up, but, as we have said before, they are really not photographic. The majority of these societies are healthy enough at present, but will they continue to be so in the future—that is, as photographic societies?

Already we have heard of the demise of several societies, and, if one can form an opinion from the annual reports and balance-sheets of some others, they are by no means in a very flourishing condition. The financial state of any photographic society must not, however, be taken as a criterion of its healthiness or otherwise. It is from the attendance of its members, and the subjects brought before its meetings, that an opinion can be

formed. As an illustration of this, we might mention that the old North London Photographic Association, many years ago, died of sheer inanition, while it had nearly 120 paid-up members, at half-a-guinea yearly subscription.

One thing is very certain, namely, that at the present time there are an unnecessary number of societies. By this we mean they are located too thickly. In some districts there are several where one only would suffice. One strong society is worth half a dozen weak ones. Subject-matter for one society may be forthcoming, but not for several. Those who have novelties to bring forward do not care to do so before small societies, and, for that simple reason, an entire district may not see them at all, though, if there were but one society, the case would be different. This is a subject that many societies would do well to take into consideration while they are yet in a healthy condition, and not defer it till they get into a more or less moribund state as some appear to be drifting into.

The Quickest Röntgen Sciographs yet Made.—These have, according to the *New York Electrical World*, been made by means of a new form of tube devised by Professor Woodward, of Harvard University. His induced currents were of 50,000 volts, and the exposures he needed were only five seconds for a hand. His new tube is made almost entirely of aluminium, in the form of a cone, strengthened against collapse from external pressure by the presence of a circular wood disc. The cathode pole is in the form of a platinum disc placed towards the base of the cone a little to one side of the centre, and its plane surface parallel to the side of the cone. It is anticipated that, with a still further increase of the voltage, instantaneous sciographs will be produced, and that it will be easy to obtain the whole of the human skeleton.

Combustion of Acetylene.—At a meeting of the Paris Academy of Sciences, on 13th inst., M. Gréhan gave some useful details upon this subject. He found the combustion in a "Manchester burner," gave a most brilliant flame, and the products of combustion did not contain any trace of unburnt gas. He gives a note of warning against the accidental admission of atmospheric air into the gas-holder, for a mixture in certain proportions is a dangerous explosive. We must, however, point out that other experimenters have advised the addition of a certain proportion of oxygen to increase the luminosity, and diminish the chance of smoky flames But this addition, made of set purpose, would naturally be safeguarded by proper precautions being taken that the due proportion should be observed. The exact ratio of air to gas which is found to be most explosive is nine volumes of the former to one of the latter.

Novel Iodine Test.—If it be desired, for example, to test for the presence of iodide of silver in a dry plate, M. G. Denigé's new method would be to dissolve the silver salts and precipitate the metal from the solution by the addition of sulphuretted hydrogen, and examine the filtrate. The latter is acidified with hydrochloric acid, boiled to expel the gas, and then supersaturated with ammonia. To the solution thus obtained is added a little caustic soda solution and a few drops of mercuric chloride solution, the whole being well shaken up. If a precipitate of a more or less deep red be observed, the presence of iodine is indicated. When no iodine is present, the deposit is white or yellowish white. It is possible to prepare a ready-made test by mixing 1 c. c. ammonia, ½ c. c. soda lye, and a few drops of solution of corrosive sublimate. Iodine in such a solution as above is indicated by the appearance of the characteristic precipitate of mercuri-ammonium iodide, mercuric oxide. It is, in fact, a fresh application of the Nessler test.

Mr. Herbert Jackson's Researches.—It is singular that an English investigator should have been working for many months previous to Röntgen's discovery without making the same generalisation as the latter. His work was with the phenomena of phosphorescence by means of the radiations from a Crookes' tube, the various substances being experimented upon both inside the tube and outside in the more familiar manner. It was during the course of his investigations that he devised a now well-known form of tube termed a focus tube. This consists of a globular tube, of which the cathode is constructed of a piece of aluminium, concave in form, the centre of curvature being sensibly in the centre of the tube. He finds the cathode rays are emitted from this concave surface in the form of a cone, whose apex lies at the centre of curvature. At this centre is placed a small platinum plane at an angle of 90° with the axis of the cone, and the Röngen rays emanate therefrom governed by certain peculiar conditions. If the tube be fairly well exhausted, the Röntgen rays appear to radiate in a cone from this centre, but, as greater exhaustion is given to the tube, this cone narrows till it becomes apparently a straight line, when the exhaustion necessary for the production of the highest phosphorescence outside the tube is attained.

The Best Phosphorescent Surface.—Mr. Jackson has tried a very large number of substances, but finds platinocyanide of potassium to be the best. This salt crystallises with three molecules of water, and should be used in its hydrated condition. As it is subject to efflorescence, special methods have to be made use of either to keep it moist or to supply moisture when required. This is rather a drawback to the employment of such a screen in actual contact with the film of a plate for increasing the photographic power of the radiations, as some reactions inimical to the production of a clean negative might be brought about.

A CORRESPONDENT, writing to *Nature*, describes another material for a luminous screen which, while not equal to a platinocyanide, is still very useful and capable of materially reducing the exposure needed. It is, moreover, a cheap substance, and compares vastly favourably with platinocyanides at sixty or seventy shillings an ounce. The substance in question is scheelite, a native tungstate of calcium, which possibly may prove to be the particular salt with which Edison's name has recently been connected. The experimenter in question powdered the material, and coated a piece of black card with it. He obtained a most notable reduction of the exposure.

Anti-halation Plates.—A correspondent senda us a suggestion for the preparation, in an easy and convenient form, of films that shall be free from all tendency to halation, and which, he considers, would be more effective in use, and more perfectly freed from any colouration in the shadows after development, than others at present employed. Briefly, the method consists in first coating the glass plate with a thin emulsion of silver chromate, which, after drying, is recoated with the sensitive emulsion of bromide of silver. The preliminary film, as our correspondent points out, will be of a deep rich red colour, quite impervious to the passage of any rays that may penetrate the bromide film; but this red colour is immediately discharged by a soluble bromide, which converts the chromate into bromide of silver, or by hypo, which dissolves it, and therefore, after development, the anti-halation colour can be as completely got rid of as if it had never been present.

WE are very sorry to put a damper on our correspondent's hopes, but, in the first place, his suggestion is by no means a new one, having been made several years ago by Mr. W. K. Burton, with the very same object in view. But, unfortunately, one or two chemical points are overlooked in the calculation. The first is, that chromate of silver is reduced without exposure to light by alkaline pyro or similar developers, and consequently, unless it was converted before reduction, the negative would be equally blackened all over. A preliminary immersion in a weak solution of bromide of potassium would effect the necessary conversion before the developer was applied, or, probably, an extra dose of bromide in the developer itself would have the the same effect; but, as this would entail the forma-

tion, by double decomposition, of potassium chromate, another influence altogether would be set at work. Potassium bichromate, as is well known, is employed in the process of emulsion-making for the removal of fog, and is recognised as a powerful destroyer of the developable image. What, then, can we imagine the effect to be upon the exposed negative image, on one of these "anti-halation" plates, of the conversion of the underlying film of chromate? Simply, that the image would be destroyed, and development rendered impossible. We repeat, we are really sorry to throw cold water on a very nice-looking process—on paper.

Chromate of Silver as a Medium for Dark-room Windows.—There is another application of chromate of silver of which greater use would be made if only the proper method of working were understood, as the emulsion of silver chromate—which was also first recommended by W. K. Burton at a meeting of the Photographic Club—is very easily made, and is, at the same time, very effective as a light filter. It is necessary, however, for dark-room purposes, to provide adequate protection against chance and flashes of chemicals, which act with very great rapidity upon the gelatino-chromate film, either to reduce or convert the chromate into bromide; but all danger is easily obviated by enclosing the film between two sheets of glass, by which it is securely protected against all chance of accident.

THE only objection we have heard raised against chromate of silver films for the purpose under notice is, that they gradually become darker by exposure to light, until, at last, it is impossible to work by the small amount of light transmitted. This was for some time quite contrary to our own experience, and it was only in the course of conversation with one who complained of the gradual darkening that we hit upon an explanation of the apparent anomaly. There are two chromates of silver corresponding in their composition to the corresponding potassium salts, so at least the text-books teach us. If a solution of silver nitrate be added to one of potassium bichromate, a dense red precipitate of silver chromate is formed, and, if this be allowed to subside, the supernatant liquid will be found to exhibit a deep yellow colour, and a similar colour will be imparted to the washing water if the precipitate be treated with repeated changes of that agent, showing that the silver salt is partially, if slightly, soluble. But, if instead of the bichromate the neutral chromate of potash be employed, the precipitate formed will differ slightly in colour, tending more to purple in tint, and will settle down, leaving a colourless, or practically colourless, upper liquid; it may also be washed in repeated changes of water without loss of bulk, or without colouration of the water, showing that it is practically insoluble.

WHETHER these are really two definite chromates of silver, or whether the apparent solubility of the precipitate formed by bichromate of potash is due merely to the presence of excess of acid in the decomposition, it is impossible to say, but it is quite clear that an emulsion containing the more or less soluble chromate with probably an excess of silver nitrate would be more likely to change, with time and exposure to light, than one in which the chromate was in the insoluble condition. The moral, therefore, is obvious: In forming such an emulsion, employ the neutral chromate of potash, and, while keeping as near to the equivalent proportions of the two salts as possible, avoid an excess of silver nitrate. If these directions be attended to, the result will be a colour filter that, under ordinary conditions, will be practically permanent.

JOTTINGS.

THE series of lectures on photography with the chromium salts organized by the Affiliation of Photographic Societies has not, so far as I can gather, filled my favourite room at 12, Hanover-square with overflowing audiences. The lectures look like being more or less of a fizzle, and I take leave to say that there is no room to be surprised thereat. Surely, carbon printing is a subject upon which it would be difficult to say anything new; collotype has been hacked to death; and Woodburytype, beautiful process though it be, is as likely to secure increased adoption as Daguerreotypy is of being revived to-morrow.

Photographic Scraps, a useful little publication, in each number of which one is tolerably sure of lighting upon a serviceable practical hint or two, has, in its April issue, a well-timed word of objection to the excessive and unnecessary degree of speed towards which several modern plate-makers are veering. It seems to me that for practical purposes we do not want plates whose sensitiveness is so great that, to quote poor Traill Taylor's favourite phrase, it has reached the condition of "tottering equilibrium," and therefore renders the avoidance of fog a matter of extreme difficulty. My own recent experiences of some high-speeded plates were that, even under the most carefully judged conditions of exposure, development, and dark-room illumination, they were so unmanageable as to render development an irksome anxiety instead of an intellectual pleasure. With phenomenal speed the fog factor assumes a prominence it does not possess with plates that will stand full exposure and normal development without resenting such treatment.

Time, in its flight, has nearly brought another Convention meeting round, and ere many weeks have passed some hundreds of us, I hope, will have assembled at Leeds under the presidency of Mr. H. P. Robinson. May I ask as many of my professional readers as can spare the time to set aside the week commencing July 13 for a visit to the Convention? To those who have never attended such a gathering I promise a happy combination of pleasure and profit, upon which, in years to come, they will look back with none but kindly feelings. Mr. R. P. Drage, of 95, Blenheim-crescent, W., is the Honorary Secretary and Treasurer. He is never so happy as when taking subscriptions (5*s.* per annum) or giving information about the Convention.

I observe, from a short article in last week's JOURNAL, that the editor passed his Easter at Southwold. Happy man! In reading the account of his wanderings, I came across a geographical slip, which I may perhaps be permitted to correct, because it will afford me the opportunity of smuggling in a reference to a somewhat similar slip of a more remarkable nature. Walberswick is spoken of as being *north*ward of Southwold. Of course, it should have been *south*ward. The other blunder I mention was made, I think, by Mr. Rider Haggard in one of his novels. In the particular passage I refer to (I quote from memory) he spoke of a noble ship steaming out of the mouth of the river Thames *towards the setting sun*. The sun usually sets in the other direction, I believe.

I have had a note made for some time to say a nice, pleasant word of Sir George Newnes, in recognition of the handsome manner in which he does justice to the many photographs he reproduces in his publications. Better blocks, better printed, of the ships, sailors, and soldiers that figure in *The Navy and Army Illustrated* would be hard to provide; while the same remark applies to *Round London*, in which one sees architectural studies of surpassing photographic excellence that deserve to be taken by the young photographer as guides for outdoor work. If all photographs were so well reproduced as they are in Sir George Newnes' establishment, photographers, block-makers, and printers would be relieved of much of the condemnation to which they are exposed at the hands of a growingly critical public.

Photographers who are compelled to adopt artificial light for projection, illuminating, studio, or domestic purposes generally, would do well to keep an eye on acetylene. It gives a beautiful white, virtually smokeless flame, and, employed without pressure, it is on all hands infinitely to be preferred to any oil lamp, to the incandescent light, and is only just sensibly inferior to oxyhydrogen with a blow-through jet. The sweet simplicity of the generating system, which merely demands that a small perforated metal cage should be filled with a chalk-like substance, and placed in a metal holder containing water, which, in contact with the calcium, disen-

gages a highly luminous gas, that has only to be conducted through rubber tubing to a suitable burner and kindled in the usual way, places the light within the reach of all. During the coming autumn we may possibly see the calcium carbide down to the price of hypo; in any event, a considerable number of cheap and handy generators will be on the market, so that photographers will have every inducement to try the light. Personally, I am charmed with it. If my readers have access to the LANTERN SUPPLEMENT of this JOURNAL for January 3 last, they will find an admirable and instructive article on the subject by Mr. Edwin Banks, probably the best article on the subject that has yet appeared.

Some of the most valuable and, at the same time, amusing information in photographic matters appears in the columns of the JOURAL devoted to the Society reports, and therefore (I fear) escapes notice on account of the dry-looking nature of the matter. For instance, at page 206 in the report of the Moseley Photographic Society, there is narrated a delicious bit of comedy, which casts a bright and instructive light on the proceedings at the meeting referred to. Dr. Radcliffe had given a lecture on *Home Portraiture*, and, the report proceeds, "the Hon. Secretary then made a few remarks respecting various points that had been raised, and made a few further suggestions which he thought might be useful to the beginner or home portraitist. Mr. Williams then said that he thought it quite unnecessary to make comments on what the lecturer had said, and thought it very presumptuous of the Hon. Secretary to take upon himself the criticism and discussion of the paper Dr. Radcliffe had so kindly given. The Hon. Secretary then called attention to a by-law which asked for comment, criticism, and discussion, and stated that he thought the greatest benefit to a Society would accrue from free and unrestrained criticism. He was sorry if he had not paid sufficient deference to the lecturer, for he felt that the greatest praise was due to the lecturer, Dr. Radcliffe, for his very excellent and instructive lecture, and proposed, as a vote of thanks that the lecturer take the fullest and most sincere thanks of an interested and instructive meeting. Mr. Williams seconded." We are not told whether the motion was carried, but it is to be presumed it was. The Hon. Secretary was, apparently, not only well within his rights in delivering his criticisms, but, upon being, curiously enough, rebuked for them, scored a great point by moving a vote of thanks to the gentleman he had taken in hand. The whole episode is very amusing, and suggests that down at Moseley they have a breezy or London and Provincial way of conducting a discussion.

The show and entertainment possibilities of the X ray boom are to be lifted from the smoky and mephitic atmosphere of the music halls and the cheap side show, and in a few days Lady Clara Vere de Vere and the "hupper suckles," generally, are to have an opportunity, in the patrician neighbourhood of Piccadilly, of submitting their delicate digits to the penetrative powers of the so-called new light. Where Society leads, the common herd usually follows—as witness the cycling fever among the fair sex—so that, in addition to its undoubted surgical uses and value, the New Photography will probably hold money for a good while to come. By the way, cycling has had to wait a long time for its boom; I wonder how long it will be before amateur photography is seriously taken up by "the classes," and will really diffuse itself widely among the masses. I question whether its possibilities as a popular pursuit have yet been realised.

COSMOS.

TRUTH.

[Photographische Mittheilungen.]

How often do we read and hear the expression "true to nature," especially in the loud trumpet-blowing praise of the new (?) three colour photography. It is used with a flippancy that can only be explained by the lamentable, widespread want of knowledge concerning art and colour. What is truth? said Pilate. What is truth in a work of art? To answer this question, first, we must be conscious of the peculiar creative method of the artist by means of which he unknowingly works out his wonderful inspiration. For some time, in personal association with painters, such as Gustav Richter, Eschke, Senior and Junior, Breitbach, the unrivalled Adolf Menzel, Knauss, Flickel, Kubiersky, Ehrentraut, Koner, and many others, we have availed ourselves of the opportunity, honourably and sincerely, to investigate their methods; and many things have suggested themselves to us, especially in connexion with those pictures, whose truth to nature is so justly appreciated by all.

Hildebrand thus paints a snow scene, and the snow is not white but blue. Is this truth? The sky is cobalt. We must examine the natural sky and cobalt through a spectroscope to comprehend the enormous difference between the blue of the heavens and cobalt-blue. And how is the sun depicted? A yellow spot, of at most fifteen candles' luminosity, whilst the real sun at the same elevation should be equal to about 6000 candles. In short, if we analyse the luminosities and the colours one by one, we find untruth upon untruth, and yet the picture, as a whole, is strikingly true, notwithstanding the blue snow and the cobalt sky. Worst of all, we do not even notice that the snow is blue, and it does not appear so, until everything but the snow is covered with black paper. The question, Why should this be? has led us to study colour, and to formulate our conclusions concerning colour perception in several articles, and they have not been without value to us in our attempts to imitate the colouring of the artist in printing in natural colours.

Unfortunately we have at the same time observed that our so-called educated public knows extremely little of art.

And how has this come about? We learn nothing of the kind in our schools; drawing only is taught, nothing of art, and in our schools for classical education the curriculum does not even include that. The representatives of so-called universal culture thus wander through the world, mostly without any art training, and they express their opinions upon works of art in a way that makes one's flesh creep.

They give pretentious definitions, impudently and dogmatically, of things they know just as much as they do of the man in the moon.

Much harm has thus been done. How can we counteract it? Not through the purse-proud financiers, who are the best customers the artists have. These gentlemen buy pictures, not because they see any beauty in them, but because they wish to get public renown for their galleries of modern works of art.

Painters say it is all the same whether our pictures are in Mr. B. Meyer's or Mr. A. Schultze's collection. The one knows as much as the other. But both can pay.

Only the school can lead the youth craving for knowledge into the right path. The optical lantern is being used more and more in our schools. This presents an opportunity for artistic, scientific, and geographical projections. We recommended this as long ago as 1870.

But we must ever remember that the finest lantern-slide, although very beautiful, may yet be untrue. This makes a knowledge of "the truth" of our photographs from nature imperatively necessary.

ASTIGMATISM AND A NEW "STIGMATIC" LENS.

[Royal Photographic Society.]

MY principal object in this paper is to treat of astigmatism with special reference to a new type of lens which I shall introduce to you later on, which is capable of giving flat images very free from this defect. In the first place, however, I think it conducive to clearness to put before you some sketch of the nature of pencils of light which show astigmatism, and spherical and other aberrations without special reference to any particular forms of optical systems, for, though we have become used to describing our lenses as having spherical and astigmatic aberrations, these qualities do not, of course, belong to the lenses, but to the pencils of light which pass through the lenses and are refracted by them. This subject has so often, and so well, been explained lately, that I fear it may be somewhat superfluous to go very fully into the question; my only excuse is that I may be able to put the subject into perhaps a slightly novel form.

In the first place, it may be considered well established that light consists of waves of small disturbances (probably of an electrical nature) which travel through transparent media with great velocity, about 180,000 miles a second, in just the same way as waves travel over the surface of a pond when a stone is thrown into it. A wave front is a surface drawn through particles of a transparent medium, which at any instant are in the same state of disturbance, just as a wave crest in the familiar instance of waves travelling over a pond is a curve drawn through the particles of water which at any instant are at the highest point which they reach in the course of their oscillations. The direction in which the light disturbance is travelling at any instant is the normal to the wave front at that

point, and this normal to the wave front is what is usually called a ray of light. A small bundle of these light rays or normals to wave fronta is what I call a pencil of light.

A pencil of light, all the rays of which pass through one point, is said to be free from aberrations. When the rays of the pencil do not all pass through a point, the pencil is said to have aberrations. Now, it is convenient to divide pencils of light into two classes, viz., small pencils and large pencils; and in like manner the aberrations into two classes—astigmatic, and what are called spherical. An astigmatic aberration is one that remains, however small the pencil of light we are considering be made, whereas a spherical aberration

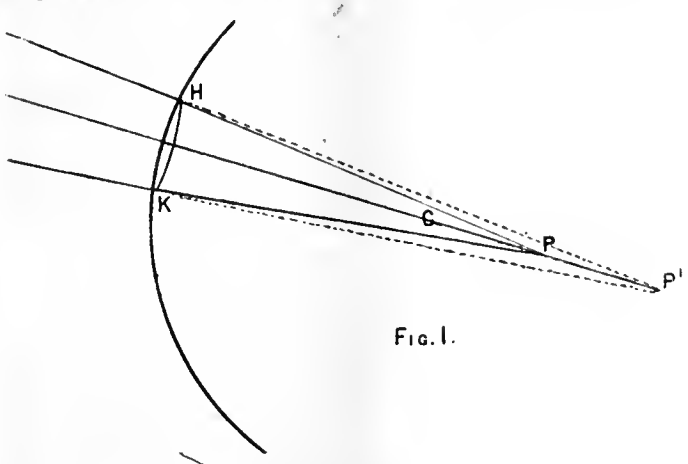


Fig. 1.

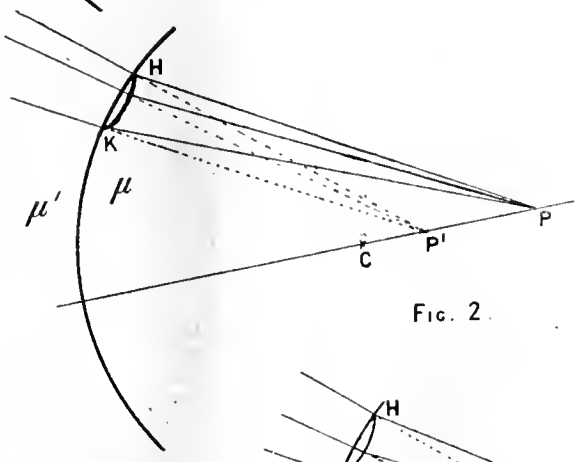

Fig. 2.

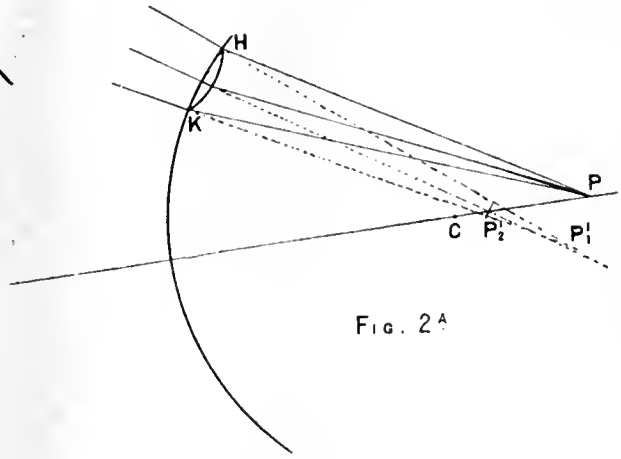

Fig. 2A

is one that tends to diminish indefinitely with the size of the pencil.

To consider first the nature of one of these small pencils, or bundles of light rays. Selecting one ray of the pencil as a principal ray, it can be shown that all the other rays, in the most general form of small pencil, pass through two straight lines which are perpendicular to the principal ray; these lines are called the *two focal lines* of the small pencil. The two planes through the principal ray, and the two focal lines are called the focal planes of the small pencil. In the perfectly general case of a small pencil, the focal planes may be inclined to each other at any angle, but in the case of a pencil of light rays, which, as I have said, are all normals to a certain wave front, it can be shown that the focal planes are always perpendicular to each other. Such a small pencil, the rays of which do not all pass through one point, but only through two focal lines, is called an astigmatic pencil. I show some models constructed to explain the arrangement of the rays of small astigmatic and non-astigmatic pencils.

This theory is, of course, only strictly applicable to pencils which are considered indefinitely small; when we come to consider pencils of finite size, the rays of the pencil remote from the principal ray will not, in general, even pass actually through the focal lines, and these aberrations of the marginal rays of the pencil come under the head of spherical aberrations. The effects of these spherical aberrations in a pencil of finite size are, in general, very complicated, and I shall have to confine myself to a few special cases as they arise.

We can now approach the subject of the effect in a small incident pencil of the refractions it undergoes in passing through an optical system. The optical systems we consider consist of any number of spherical surfaces separating homogeneous refracting media, the centres of these spherical surfaces lying along a straight line which we call the axis of the system. Now, when a small non-astigmatic pencil of light rays is incident as a spherical refractive surface, the emergent pencil invariably shows these two focal lines of astigmatism, except in two special instances (figs. 1, 2, 2A):—

(1) When the incidence is normal, *i.e.*, when the small pencil passes through the centre of the refracting surface as in fig. 1.

(2) When the point from which the rays of the pencil diverge before incidence is at a certain distance from the centre of the refracting surface, *e.g.*, if we have a small pencil, PHK, diverging from a point, P, incident as a refracting surface where centre is C, then, if PC bear the same ratio to the radius of the surface as refractive index of medium of emergence is to refractive index of medium of incidence, then the part of pencil after refraction will all accurately pass through a point, Q, and this will be true, even if the pencil be of finite size as fig. 2 (fig. 3).

Now let AB be an optical system, PP^1 its axis, and let PQ be a flat object. Every point in this object is giving out rays of light, some of which pass through the optical system, and are refracted by it. Let P be a point in this object, and on the axis of the optical system. Let us consider the refraction of a small pencil emerging from P, and incident in the optical system along its axis, PP^1. Since this pencil will be everywhere nominally incident on the surfaces of the optical system, it will emerge without astigmatism, and it will therefore come to a focus at some point, P^1, in the axis of the system, P^1 being, in fact, the conjugate focus of P.

Now consider some point, Q, on the flat object, not on the axis of the system, and consider the refraction of a small pencil diverging from Q, whose principal ray lies in the plane containing Q, and the axis of the system, which we shall call the primary plane of the small pencil. Let QR be this principal ray. It is easy to see that, after refraction through the system, this principal ray will still lie in the primary plane, but, since the incidences of this small pencil are not in general normal, this small pencil after refraction will in general show astigmatism. It can be shown that one focal line (the primary focal line) will be perpendicular to the primary plane, and the other focal line (the secondary focal line) will lie in the primary plane. The points where these focal lines meet the principal ray of the emergent pencil we call the primary and secondary foci of the emergent pencil; let Q_1^1 Q_2^1 be these primary and secondary foci. Then Q is, in fact, the focus of rays of this small pencil which lie in

the primary plane, and Q_2 is the focus of these rays which lie in a plane perpendicular to the primary plane. Now draw two spherical surfaces whose centres are on the axis of the optical system, and which pass respectively through the points P^1 and Q_1^1 and P_2^1. The inverse of the radii of these two surfaces I call the curvatures of the primary and secondary images of the plane object given by the optical system employed with a small stop at R.

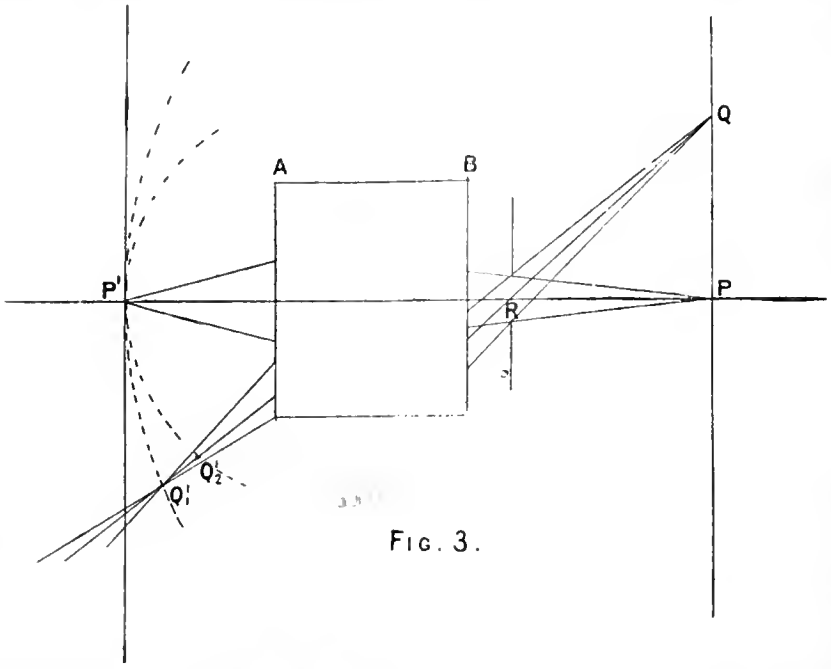

FIG. 3.

Now, both the primary and secondary curvatures depend in general—

(1) On the position of the small stop, R.
(2) On the distance of the object, PR, from the lens.
(3) On the nature of the optical system.

There is, however, a relation between the primary and secondary curvatures of the image, which I think I can call extraordinarily simple, considering how very complicated are most of the results which are obtained in the general theory of optical systems, and it is this, that, if from the curvature in the primary plane we subtract three times the curvature in the secondary plane, we obtain a quantity which is independent—

(1) Of the position of the stop, R.
(2) Of the distance of the object, PR.
(3) Of the thicknesses of the component lenses of the system and of their separations.

In fact, this quantity (one half of which I call the astigmatic constant of the optical system, denoted by U) is a function only of the curvatures of the surfaces and refractive indices of the glasses of which the system is composed. In fact, if by alteration of the position of the stop, or position of object, or thicknesses or separations of the lenses, we alter the curvature in the secondary plane by a certain quantity, we shall alter the curvature in the primary plane by three times that quantity, leaving the astigmatic constant unaltered. When I first discovered this result, I was so much surprised at its simplicity that I concluded that I must have made some mistake in my work. I soon, however, discovered by actual experiment that optical systems did, as a matter of fact, obey this law, and soon after I found that Airey, the late Astronomer-Royal, had actually proved this result for an optical system in which the component lenses are indefinitely thin; his work is reproduced in an early work on optics by Coddington (published in 1829). Airey apparently did not see that the result applied to a system of thick lenses, and it is certainly strange that the result remains absolutely unaltered, however thick the lenses of the system may be. In consequence of this law, the labour of constructing lenses on a purely theoretical basis is very much lightened; in fact, it is only necesary to consider the action of the optical system on the rays of pencils which lie in the primitive plane; for instance, if we construct an optical system which gives zero curvature in primary plane, we can at once deduce the curvature in the secondary plane from knowledge of the astigmatic constant of the system; in particular, if the astigmatic constant be zero, it is at once evident that the secondary curvature will also vanish. Now, it is our object to produce optical systems with a flat field free from astigmatism, in other words, with zero curvature in both primary and secondary planes. One condition, then, that such a system must satisfy is that the astigmatic constant must vanish. Now, as I have said, the astigmatic constant may be exhibited as a function of the curvatures and refractive indices of the component lenses. I shall, however, content myself with stating that, when the astigmatic constant vanishes, the sum of thicknesses of component lenses in the centre must be equal to the sum of thicknesses at the edge, or rather at some definite distance from the centre, each of such thicknesses being multiplied by a certain factor depending on the refractive index of the glass of which the lens is composed. For crown glass of low refractive index this factor is $\frac{1}{3}$, and for heavy flint glass this factor is $\frac{3}{8}$. Since these factors are very nearly equal (being in fact as 8 : 9), we see that in our "stigmatic" lens the aggregate thickness of component lenses in the centre must be (approximally) equal to the aggregate thickness at the edge. I can now give you a brief sketch of how such system can be constructed.

H. L. ALDIS, B.A.

(To be continued.)

PHOTOGRAPHY WITH THE BICHROMATE SALTS.

THE series of lectures upon this subject, arranged in connexion with the Affiliation of Photographic Societies with the Royal Photographic Society was commenced on Wednesday, the 15th inst., at the rooms of the parent Society, when Captain W. de W. Abney, C.B., D.C.L., F.R.S., delivered a scientific and historical preliminary lecture. The chair was taken by Mr. W. Thomas (Chairman of the Affiliation delegates), and there was a very small attendance. Captain Abney began with the discovery by Mungo Ponton in 1839, that ordinary paper, when soaked in a solution of bichromate of potash, was sensitive to light and showed a print produced in that manner, and proceeded to detail the subsequent investigations of Becquerel, Fox Talbot, Poitevin, Burnet, Fargier, Swan, and Johnson. Burnet's method of exposing through the back of the tissue suggested a means of utilising spoilt celloidin films, which, being immersed in a three per cent. solution of bichromate of potash and dried, would yield very good transparencies if exposed under a negative and developed with hot water in the usual manner, the print being afterwards intensified in an ordinary dry-plate developer. This was very similar to Mr. Bolas's method of producing reversed negatives, except that in that case the soluble gelatine was not washed out. Having sketched the principles of collotype, Woodburytype, and photo-lithography, the lecturer pointed out that the common yellow chromate of potash was also sensitive to light, and showed a transparency produced by that salt instead of the bichromate. He alluded to his experiments many years ago with regard to regard to the continuing action of light upon bichromated gelatine, and to the intensification of carbon transparencies by means of permanganate of potash. Incidentally, a protest was made against the meaning ordinarily attached in England to the word *actinic*. All rays of light were alike, and their effect depended upon the nature of the substance upon which they fell. Captain Abney showed that bichromate cut off the whole of the blue and a good deal of the green of the spectrum, and said it might be expected that the light which was active was that which the bichromate absorbed.

At the conclusion of the lecture the Chairman conveyed to Captain Abney the thanks of the Committee and also of the audience assembled.

The second lecture was given on Friday, April 17, by Mr. J. A. Sinclair (the Earl of Crawford presiding), upon the subject of *Carbon Printing*. In the course of a brief *résumé* of the various stages in the evolution of the process, he said that Blair's system of printing without transfer, invented in 1863, appeared to be identical with the Artigue process. Blair coated plain paper with gelatine slightly tinted on the surface, and soluble only in hot water, after which it was again coated with a mixture of albumen and syrup, bichromated, and dry carbon was then rubbed all over the surface. A demonstration of carbon printing by single transfer was given, and some prints on Artigue tissue were also developed. As a substratum for enabling drawing paper, &c., to be used as a final support, Mr. Sinclair recommended a five per cent. solution of gelatine, to ten ounces of which twenty drops of formalin should be added. The development of Artigue prints by means of very fine sawdust mixed with water was watched with much interest; the minute particles of sawdust had the effect of a fine file upon the surface of the tissue, dragging away the soluble portions of the film, and leaving the unreversed picture. He thought prints by this process would be found to contain details sufficiently harrowing to satisfy even "Dogberry." M. Demachy had sent over for exhibition a number of examples of the bichromated gum pro-

cess, which he had said must not be presented as an easy one, a qualification which Mr. Sinclair said applied equally to the Artigue method, and he thought both of them were too difficult to become commercial.

Votes of thanks were accorded to Mr. Sinclair and M. Demachy, and also to the Earl of Crawford for presiding. The attendance on this occasion was rather larger than before, but still disappointingly small, and it is much to be desired that the remaining lectures of the course will attract increased audiences.

The following are particulars of the next two lectures:—

Friday, April 24, *Collotype*, by W. E. Debenham, Esq.—Syllabus: Principles on which collotype depends—Albert's method—The modern process with water glass—Cleaning and grinding the plate—The first coating to secure adhesion of the printing surface—Drying and washing—The preparation of the second or sensitive coating—Details of precautions employed to ensure success—The drying oven—Applying the second coating—Drying—Preparing the negative for printing—The pressure frame—Exposure and washing out of the soluble salts—Drying—Details of the printing process—The press, rollers, and ink—Damping, or the so-called etching process—Demonstration of the work.

Tuesday, April 28, *Woodburytype*, by J. D. Geddes, Esq.—Syllabus: General principles—Negatives—Preparation of sensitised films and printing—Washing and drying reliefs—Hydraulic pressure and appliances—Metal moulds and preparation for printing—Waterproofing paper and ink—Printing—Fixing—Mounting—Various applications.

M. LIPPMANN ON COLOUR PHOTOGRAPHY.

Last Friday evening, at the Royal Institution, M. Lippman gave a most interesting lecture on *Colour Photography*, and a demonstration on the screen of some of the results. That something of more than usual interest was expected could be seen by the hurried way in which coats and hats were deposited, and a seat sought, in the lecture hall, even fifteen minutes before the time announced for the lecture. The number of well-known F.R.S.'s and scientific men who had put in an appearance testified to the fact that not only was an invention to be described, but also that there was a desire to suitably welcome and honour a French *savant*.

M. Lippmann prefaced his lecture with a few introductory remarks in French, but his apologies for any shortcomings as regards the English language were (as it turned out) unnecessary, for he spoke with remarkable clearness, and in language that was easily understood. He gave E. Becquerel the credit of the first serious work in colour photography, at a date about 1840, when he succeeded in taking a photograph on which colours were shown, but they could not be fixed, and so were only available in a dark room or place free from actinic light. He used sublimate of silver. In 1861, Charcot, Durand, and a German, all about the same time, were at work on three-colour photography, and, although he was of opinion that there is a great future for this, still the fact that three separate photographs have to be taken left it short of his ideal, especially as colours or pigments had to be employed.

He described his own plan as the "interferential method," and it is performed by one exposure only, and any film can be used and developed in the ordinary way. The only addition to the dark slide of the camera is a mercurial or silver backing to act as a reflector. When this announcement was made, the audience were enthusiastic to a degree, and no wonder, for the charm was in the simplicity of the invention. As the most convenient, he arranged his dark slide with an extra space, and, when the plate is put in position, a valve allows the mercury to flow down behind it, and forms a perfect reflecting surface. The photographic film is exposed with the glass side to the lens and light, and when developed with acid or alkaline developer, and fixed with cyanide of potassium, the natural colour can be seen by reflected light. It is necessary to so hold the photograph that these reflected rays fall on it in the proper position, as otherwise it is only black and white as used in a negative or positive. A dark backing is also required to the photograph.

Several photographs taken by this method were projected on a small screen, and to do this an electric opaque lantern was employed, the operator fixing the subject on to a rod that permitted it to be turned so as to get the colour from reflection of the incident rays. Among the subjects were a stained-glass window; a lawn, with lady sitting on a chair, and having a background of trees; a house illuminated by sunlight, with climbing plants on the walls; a mansion with tower and garden; groupings of flowers and fruit, and a gaily coloured parrot. It was stated in respect of the flowers taken in sunlight that a three minutes' exposure was given.

M. Lippmann, in his explanation of the results obtained by this process, used the phonograph for a simile or analogy, and said his opinion was that, as sound waves are inscribed on the phonograph diaphragm, so light waves were impressed on the film after reflection. A simple and telling experiment demonstrated to the audience that waves are both direct and reflecting, and at certain positions, where the two sets of waves meet, there is what is known as standing waves. A long indiarubber tube, attached near the ceiling, was set in motion from the floor, and the waves ran up to the top, and then returned in complimentary waves. By increasing the motion loops were formed of these waves, and at definite intervals there was no motion. The mercury reflector sent the waves of light back, and at half-wave lengths of the incident rays the colours of those rays proceeding from the object were impressed on the sensitive film.

The interference of light was well shown by making a sensitive film damp and placing it in the rays of the electric lamp in the opaque lantern. As the film dried, most beautiful colours were shown on the screen.

The best sensitive plates for the purpose of colour photography by this method are gelatine bromide, with gelatine in excess to about thirty per cent. by weight, and an ideal plate should be perfectly isochromatic.

As M. Lippmann had been at work ten years before he hit on this happy idea of the mercurial reflector and modified plate, it proves the old adage of perseverance, and that the try, try, try again policy nearly always leads to success.

Our Editorial Table.

Catalogue Received.

Marion & Co., Soho-square, W.

An advance copy of the new catalogue just being issued by Messrs. Marion has reached us. We turn over its 136 large pages, which are lavishly illustrated and printed with rare excellence, and find that the volume evinces every sign of having been compiled with a shrewd regard to the actual requirements of the photographer of the moment. There are not, as in some catalogues we occasionally have sent us, obsolete or useless items of apparatus or sundries figuring in Messrs. Marion's catalogue. It is full of good things, suitable alike to the amateur and professional. A feature is made of Voigtlander's collinear lens, and many others of Messrs. Marion's specialities. The catalogue is sent post free for 1*s*.

Received: Results of Meteorological and Magnetical Observations at Stonyhurst College Observatory. 1895. By Rev. W. Sidgreaves, S.J.

The Frena Exposure Book.

R. & J. Beck, 68, Cornhill.

This little book, which is compact enough to be carried in the pocket, supplies a number of ruled pages for recording particulars of "Frena" exposures. By way of preface, there are given some useful notes on the duration of exposure for moving objects, table of movement, use of the swing back, packing films, and other information calculated to be of service to the users of Frena cameras.

The Year-Book of Photography and Amateur's Holiday Guide, 1896.

London: The Photographic News, 22 Furnival-street, E.C.

Besides appearing earlier in the year than hitherto, the *Year-Book* of our contemporary assumes, in the 1896 volume, which is now before us, some features that were not to be found in preceding issues. It is divided off into five sections, the first of which includes a number of articles on topics of practical interest by H. P. Robinson, Bothamley, Vincent Elsden, Hector Maclean, and other authorities; facts and formulæ, relating to development, printing, toning, and other operations, compiled by Mr. E. J. Wall, fill Section II.; the Rev. F. C. Lambert in Section III. sets forth in detail much useful and varied information with regard to photographic touring to various points of interest on the coast, and following upon a section devoted to lanterns and their accessories, the volume winds up with a terse and serviceable review of recent novelties in apparatus, &c. There are several illustrations, and the book, which reflects credit on all concerned in its preparation, shows by the nature, variety, and excellence of its contents that the requirements of the class of readers to which it appeals have been carefully studied.

News and Notes.

LANTERN SOCIETY.—On Monday, April 27, the subjects on the programme are: 1, *Stereoscopic Projection with the Lantern*. 2, *Among the Bees with a Camera*, by Mr. T. E. Freshwater, F.R.M.S., F.R.P.S.

THE KINEOPTICON.—A successful demonstration of Mr. Birt Acres' invention for showing animated photographs on the screen, to which we referred in our issue of March 27, was given in the rooms at Piccadilly-circus on Monday last.

MR. J. T. PATTISON, of Fawley Lodge, South Woodford, Secretary of the Sunbeam Postal Photographic Club, desires us to state that there are a few vacancies in the Club, and that he will be pleased to send full particulars to any photographers wishing to join.

WOLVERHAMPTON PHOTOGRAPHIC SOCIETY.—This Society will hold an Exhibition of Members' Work in the Blind Institute, Victoria-street, Wolverhampton, on Tuesday, May 5, 1896. The Judges are Dr. Hall Edwards and Mr. E. C. Middleton. The Hon. Secretary is Mr. G. Hanmer, 2 Dudley-road, Wolverhampton.

THE Editors of the *Photogram* write: "Will you do us the great favour of allowing us to ask your readers for their assistance in making *Photograms of* 1896 worthily representative of the present position of photography. This is the only annual attempting to reproduce the best work of the year, and we are anxious not to miss seeing anything that is really meritorious."

IGNITION TEMPERATURE OF ACETYLENE GAS.—Mr. A. E. Coldwell writes to the *Scientific American*: In experimenting recently with acetylene, I was surprised to find its ignition point so low that it would take fire through the gauze of a Davy lamp. I tested it by lowering the lighted lamp into a jar of the gas and also by directing a jet of the gas against the lamp. In both cases the acetylene took fire outside the protecting gauze about as easily as hydrogen would. CH_4 and C_2H_4 will not ignite in this way, and it seems strange that the higher carbide C_2H_2 should. It must be very unstable.

SHEFFIELD PHOTOGRAPHIC SOCIETY.—The Annual Musical Evening in connexion with this Society took place on Tuesday, April 13, at the Masonic Hall. The President (Mr. Nowill) occupied the chair. The first part of the programme was a lantern exhibition, consisting of a set of slides of interiors of English cathedrals and of Windsor, lent by Messrs. R. W. Thomas & Co. (Limited), and, by way of variety, a few slides made by members of the Society were also thrown on the screen at intervals. The lantern was under the management of Mr. E. Beck, who also announced the titles of the pictures. The second part consisted of vocal and instrumental music.

ACETYLENE is being tried as an illuminant on the Paris tramcars. The gasogene, containing calcium carbide and water, is placed on the rear platform underneath the steps. Though its weight when charged is only twenty-seven pounds, it is capable of producing thirty-five cubic feet of the gas, the illuminating power of which is estimated at fifteen times that of ordinary coal gas. The lighting is said to be very efficient, it being possible to read a paper in any part of the car. The cost, so far as the experiments have yet gone, works out at less than that of lighting by petroleum; but, as the car has only been in use some six weeks, it is not yet possible to give definite figures.

RADIOGRAPHS BY FLUORESCENT SCREENS.—"It may perhaps interest those who occupy themselves in photographing with Röntgen rays," says Herr Bleekrode in *Nature*, "to know that a very effective and rapid method is obtained when proceeding as I will explain. I had a piece of scheelite or native tungstate of calcium, such as occurs in a collection of minerals, crushed to a somewhat coarse powder, and made it into an emulsion with gelatine; this was applied in a consistent and uniform layer on a piece of stiff black paper, and after this was dried the surface showed numerous crystalline, glittering particles. The right condition for fluorescing was attained, as was evident, when a Crookes' tube in action was placed behind and looked at in the dark, though the luminosity was not so strong as with a screen covered with crystals of platinocyanide of barium. The paper, thus prepared, was simply laid down on a very sensitive photographic glass plate, with its fluorescent side, of course, in contact with the film; on the upper surface metallic objects or the fingers were put. Applying now Newton's focus tube (which, I may add, gave me excellent results in former experiments) with an induction coil, regulated to give sparks of five to six inches, I obtained sharply defined radiographs of keys, &c., in twenty-five seconds, and of the fingers, showing the bones and metallic objects hidden between them and the plate, in ninety seconds, distinct enough to perceive even the eye in a needle that was put in the epidermis. I also tried the fluoride of calcium mentioned by Professor Winkelmann, of Jena, but I perceived no fluorescence, perhaps because the powder was amorphous throughout. As scheelite is a very cheap mineral, large screens with fluorescent surfaces may be constructed at a trifling expense."

PHOTOGRAPHIC EXHIBITION AT WEXFORD.—Last week the first Photographic Exhibition held in Wexford was opened in the Town Hall. Not only from the point of view of the number of exhibits and the interest taken in the Exhibition by the local amateurs and the public generally, but also from the real merit of the photographs, the Exhibition has been voted on all sides an exceptional and unqualified success. The large number that filed down the stands in the Town Hall were not alone charmed by the array of first-class pictures of every kind, but very much surprised indeed at the undoubted merit displayed. There were on every side convincing proofs that amateur photography has seized hold of some of the best artistic talent in the county. It could be seen, too, that this talent was of no mean order, and, supplemented by extreme care and attention, has been put to use in the best possible manner in producing fine pictures. It was in the Enlargement Class that the highest successes were gained. In this class the exhibits of Dr. Drapes (Enniscorthy) won the admiration of all. There were several fine pictures of his on show, and it was a difficult task indeed to select the best. When, however, the Judge gave the first prize to *The Crofter's Home*, the public unanimously endorsed the decision. The fine collection of pictures from Mr. M. A. Ennis's studio attracted considerable attention and admiration. A very artistic lot were the portrait groups by Miss Jefferies, Newbay. Among the other successful contributors were Messrs. J. B. Pettigrew, Herbert Sutton, F. Owens, J. E. Sbannon, E. S. O'Brien, B.E., J. O'N. F. Kelly, D.I., R. C. Roche, W. H. M'Guire, &c. The following are the awards: Class I. (Quarter-plate Landscapes), first prize, F. O'Neill Kelly, Wexford; second prize, F. J. Owens, Wexford. Class II. (Half-plate and larger-sized Landscapes), first, A. H. Sutton, Wexford; second, A. H. Sutton, Wexford. Class III. (Quarter-plate Portraits and Groups), first, Miss J. E. Jefferies, Newbay, Wexford; second, Miss J. E. Jefferies, Newbay, Wexford. Class IV. (Half-plate and larger-sized Portraits and Groups), first, Miss J. E. Jefferies; second, J. B. Pettigrew. Class V. (Instantaneous Subjects on Land), first, M. A. Ennis, Wexford; second, M. A. Ennis, Wexford. Class VI. (Instantaneous Subjects on Water), first, J. B. Pettigrew, Wexford; second, J. B. Pettigrew, Wexford. Class VII. (Interiors), first, E. S. O'Brien, Wexford; second, M. A. Ennis, Wexford. Class VIII. (Enlargements), first, Thos. Drapes, The Asylum, Enniscorthy; second, Thos. Drapes, The Asylum, Enniscorthy. Class IX. (Lantern Slides), first, F. J. Owens, Wexford; second, F. J. Owens, Wexford. Class X. (Opals), first, M. A. Ennis, Wexford; second, M. A. Ennis, Wexford.

THE CHEMIST'S ELECTRIC FURNACE.—Feeling that his Royal Institution audiences have had enough freezing at the bottom of the thermometric scale, Professor Dewar, in his new lectures commenced last week, decided to give them a little roasting at the top. In a word, he has ceased to discourse on the behaviour of bodies at 200 degrees of frost, and has commenced to describe the condition of things when the thermometer registers about 4000 or 5000 degrees "in the shade." Now, there is only one place on earth as hot as this, and that is between the carbon points of the electric arc light. It is a little cooler within the crucible of the electric furnace proper, but the difference is not of much practical importance. The chief lesson inculcated at last week's lecture was the extraordinary significance of the recent discoveries made by M. Moissan, of Paris. In the electric furnace Moissan has shown that carbon will do that which it will not at any lower temperature, namely, unite directly with such elements as calcinm (the metal of lime), strontium, varium, aluminium, yttrium, and other elements of high density. The combinations so formed are called carbides. Their most remarkable feature is the way they break up or decompose when placed in water, giving rise immediately to hydrocarbon gases, which chemists have been trying in vain for generations to prepare otherwise than by roundabout and costly processes. Professor Dewar took the simplest case—carbide of calcium, which he prepared by simply mixing together lime and powdered graphite (carbon), and fusing them in the furnace. This carbide is a grey fused mass. Throw it into water and it immediately generates acetylene, a gas which is rapidly coming into use for illuminating purposes, since it gives a light eight times more brilliant than coal gas, and its little flame rivals the incandescent lamp. Hitherto this gas has been little more than a chemical curiosity, prepared only by costly and roundabout processes. But this is not all. If you pass the acetylene gas through a red-hot tube, the strangest thing happens. The gas begins to glow as if it were on fire inside the tube, and in the "twinkling of an eye" you are manufacturing "benzole"—that philosopher's stone of modern chemistry—the basis from which all our aniline dyes are prepared, and the parent of the hundreds of valuable substances which are known generally as "coal-tar derivatives." Hitherto benzole has been prepared by long and complex processes from coal tar. Finally, Professor Dewar spoke of some other furnace carbides, and their behaviour when placed in water, which is strange. Carbide of aluminium gives off "marsh gas," but the carbides of cerium, uranium, and other rare metals of great density beat the record by giving off nothing less than crude petroleum.

FAKENHAM EXHIBITION.—An Exhibition of Arts and Crafts, promoted by the Fakenham District Camera Club, was held under distingnished patronage in the Corn Hall, Fakenham, on Tuesday and Wednesday, April 14 and 15, and included a large number of photographs, photographic appliances, oil and water-colour paintings, art needlework, carvings, etchings, pencil and crayon drawings, &c. There was also a loan collection of paintings, engravings, curios, statuary, and natural history exhibits. The Exhibition was opened on Tuesday by the Rev. William Martin (President of the Club), who, in a neat speech, congratulated the Committee and the Secretary on the marked success of their efforts. He also drew the attention of his hearers to the great strides photography had made during the last ten years, and to its claims to be called a fine art; as an enthusiastic amateur whose experience dated back to the wet-plate days, he had watched with great interest the wonderful growth and ever-increasing usefulness and popularity of the art-science. On the Wednesday, the Exhibition was opened by the Countess of Leicester, who expressed her pleasure at seeing such a fine show, and hoped it would be in every way a success. There was a good attendance of the public on both days. The evenings were enlivened by the strains of an excellent string band, under the conductorship of Mr. R. S. Utting. The pictures and photographs lined both sides of the large hall, while the other exhibits were effectively displayed on stages draped with Indian cloths and art muslin. The assembly-room adjoining the main hall was set apart for lantern exhibitions of members and other slides, given each evening at eight o'clock, and lectures on the Röntgen X rays by Dr. Fisher, acting as substitute for Dr. Thomson, of Norwich, who was unable to attend. The limelight lantern was worked by the Messrs. Davis in their usual effective manner. The following were the awards in the competition classes:—General Photographic Work: 1, R. W. Copeman; 2, G. H. Davis; certificate, N. W. Hughes, W. H. Clutterbuck, E. A. de Haven. Enlargements: 1, R. W. Copeman; certificate, W. H. Clutterbuck. Mr. W. Tylar, of Birmingham, showed his well-known Tit Bits hand cameras and a collection of useful and ingenious photographic novelties. Amongst other stalls were noticeable that of Mr. J. J. Roberts, of Fakenham, with some fine enlargements; Mr. H. Applegate, of Fakenham, good general portrait work; Mr. R. W. Newman, of Fakenham, a tastefully arranged display of golf clubs, cricket bats, tennis rackets, &c.; Messrs. Bone & Readwin, of Fakenham,

bicycles, leather work, &c. The photographic work of Messrs. W. H. Clutterbuck, R. W. Copeman, C. H. Davis, and N. H. Hughes was of a high standard, as was also that of Mr. C. Wood, who exhibited a book bound by himself containing 180 views taken on a cycle tour. Some fine artistic work sent in by Mr. C. Hewitt, of Gateshead, unfortunately arrived too late to compete. Mr. Sydney M. Broad's landscape paintings were highly praised.

Patent News.

THE following applications for Patents were made between April 8 and April 15, 1896:—

DARK SLIDES.—No. 7365. "A Self-dusting Dark Slide for Photographic Cameras." R. MOODIE.

PHOTOGRAPHIC APPARATUS.—No. 7448. "Improvements in Photographic Tripod Stands, Printing Frames, and Cameras." H. J. SPRATT, A. S. SPRATT, and G. A. SPRATT.

PRINTING.—No. 7462. "Apparatus for Photographically Printing Continuous Strips." B. ACRES.

CAMERAS AND LANTERNS.—No. 7528. "Improvements in Combined Cameras and Optical Lanterns." B. DOYLE.

WASHING VESSEL.—No 7715. "An improved Photographic Washing Vessel." A. A. BRADBURNE.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
27	North Middlesex	*Copying.* H. W. Bennett.
27	Camera Club	Members' Annual Exhibition of Pictures opens.—The President (Captain W. de W. Abney, C.B., F.R.S., &c.), Opens the Sixth Annual Conference.
27	Lantern Society	*Stereoscopic Projection with the Lantern.—Among the Bees with a Camera.* T. E. Freshwater, F.R.P.S., F.R.M.S.
27	Oxford Camera Club	*Radiography; or, Photography by Röntgen's X Rays.* E. A. Ryman-Hall and E. L. B. Hill.
27	Richmond	*A Visit to India and Burmah.* Dr. C. Wymen.
28	Bournemouth	*The Modern Hand Camera and How to Use it.* F. O. Bynoe.
28-30	Camera Club	Continuation of Conference.
28	Hackney	Exhibition and Competition.
30	Bradford	Annual Meeting.
30	Liverpool Amateur	*Five Hundred Miles up the Nile, or from Cairo to the First Cataract.* David Lewis.
30	London and Provincial	*English Cathedrals.* Mr. Evans.
30	Oldham	Exhibition of Members' Transparencies.
May.		
1	Aintree and District	Stereoscopic Photography.
1	Camera Club	Annual Club Dinner.
2	Borough Polytechnic	Excursion: Kew and District.

ROYAL PHOTOGRAPHIC SOCIETY.

APRIL 21,—Photo-mechanical Meeting,—Mr. Leon Warnerke in the chair.

Mr. T. BOLAS, F.I.C., F.C.S., read a note as to the evolution of

PHOTOGRAVURE METHODS IN INTAGLIO AND RELIEF.

Camera photography and photogravure, he said, took their birth between 1813 and 1816, by the labours of Nicephore Niépce, one of whose cameras, which he called an "artificial eye," being still preserved in the museum of Chalon-saur-Saone. His process was first called "Heliographie," but finding that direct sunlight was not essential, the name was changed in 1816 to "Photographie." The earliest work of Niépce now known to be in existence is a photogravure of a portrait of Cardinal d'Amboise, made in 1824; and the first photogravure plates made in this country were produced by Mr. W. R. (afterwards Mr. Justice) Grove, who about 1840 made the Daguerreotype plate the anode in an electrolytic cell, and obtained a very delicate intaglio. After referring to the work of Chevalier, Mr. Bolas described Claudet's method of etching Daguerreotype plates, in which the hollows were filled with ink and the bare parts gilded, so that the gold film could be used as a resist in further etching. Talbot etched through a film of bichromated gelatine, which was continuous but unequally hardened by exposure under a transparent positive, while Pretsch obtained his plate by moulding from the swelled and reticulated gelatine film. Talbot suggested the use of textile screens, and Burnett suggested ruled glass screens or random dots, Berchtold also mentioning line screens on glass, with shift at right angles. The Talbot Klic process now gave the very best results in photogravure for the typographic press. The fundamental advance made by Ives in 1878, which Mr. Bolas fully described, introduced a definite mechanical method of translating the gradation of the Woodbury relief into dots of correspondingly graduated area, the principle depending upon the compression or flattening of an elastic pyramid to a degree proportionate to the height of the relief. Mr. Ives's subsequent method of graining the negative by putting a ruled screen before the plate in the camera, so that each window in the screen should form a pinhole image of the diaphragm aperture, had now become general. Mr. Bolas exhibited a considerable number of most interesting prints by the various workers in connexion with the different processes, many of which were regarded as quite equal to the productions of the present day.

Mr. F. E. IVES, alluding to his method of mechanically translating the Woodburytype relief into lines and dots, said that Charles Pettit, of Paris, made a cast of the relief, inked the surface, put it in a planing machine, and cut V-shaped grooves in it, and in that way translated the relief into mechanical lines, and the date of record for this process was five days earlier than Mr. Ives's date of record for the impression method which accomplished the same result.

Mr. H. WILMER and the Rev. F. C. LAMBERT raised a question as to whether a carbon resist could be laid on to the copper plate without a grain, and said it was quite possible to do so without the film lifting in the etching.

Mr. BOLAS said his experience was that the film would not hold down without a grain.

Mr. W. GAMBLE thought it was largely a matter of the management of the perchloride of iron, which would lift the film if it contained much free acid.

The CHAIRMAN said the gelatine image formed a better resist if it was kept at least a day before etching, and, if heated, it would resist still more satisfactorily.

The Rev. F. C. Lambert showed a film which had stripped from a grained plate in consequence of too rapid drying.

Mr. BULLEN remarked that better results would probably have been secured by Pretsch and others if they had been able to obtain ink and paper of the quality now obtainable.

Mr. IVES said Dr. Eder's Year Book credited him with the invention of the fish-glue process; but, although that was developed under his personal supervision, it was a modification of a French photogravure process adapted to the production of relief plates, the formula for which was found in an old Year-Book.

Mr. GAMBLE showed the first photo-zincograph ever made, produced by Colonel Sir Henry James.

The subject was further discussed conversationally by the Chairman, Mr. Chapman Jones, Mr. Debenham, Mr. Ives, and others, and the meeting closed with a vote of thanks to Mr. Bolas.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

APRIL 16,—Mr. A. Mackie in the chair.

The HON. SECRETARY, referring to the desire to have a portrait of the late Mr. Traill Taylor, expressed at a previous meeting, said Mr. Hay Taylor had kindly obliged him with a negative, and he had made a carbon print, which he now presented to the Association, and passed round. It was decided to frame and hang it in the meeting room.

RESIDUES.

The following question was read: "What is the best course to follow to regain gold residues and make into chloride for use?"

Mr. RAPSON, who wished to obtain this information, said he had about an ounce of residue, and asked whether, after dissolving in mixed acids, it would require any other cleaning to get rid of the acetate of soda, &c. He also required to get rid of the slight remaining acid still present after evaporation.

It was recommended to precipitate with iron and dissolve with acid, followed by repeated evaporation. Care should be taken to remove all the iron also, to prevent the reduction of the gold again. The addition of chalk to neutralise the acid was suggested.

HALATION.

The HON. SECRETARY said during a recent discussion various suggestions were made for avoiding halation, since which he had made some further experiments. They had discussed the question of plates *versus* films, and while away at Easter he had tried films for the prevention of halation with good results. The picture shown was taken directly in front of an east window, with an exposure of ten minutes at *f*-45, and there was scarcely any trace of halation in this window, speaking very well of the use of films for interior work. He had also tried exposures on the vexed question of the front of the plate *versus* the back of the plate, the test in this case being a naked gas flame. The results were in favour of exposing directly on the film in the usual way, and not through the glass. Regarding the question raised by Mr. Freshwater as to the possibility of avoiding halation in development, he very much doubted, unless one used very thickly coated plates, that it could be done. If one could get a very opaque film which absorbed all the light falling upon it, he thought the evil could be avoided to a very large extent. With thin films, however, it was different. There may be some gain in development, but not a marked difference under the same conditions. Of course, with the carbon process, it was very convenient to expose through the glass, and it would be interesting to learn how to overcome halation under these conditions.

Mr. W. D. WELFORD inquired what the effect of a blemish in the glass would be in exposing through the glass, local or otherwise?

The CHAIRMAN thought it would be local.

Mr. WELFORD said there seemed to be an impression that films would not give halation. He could show plenty demonstrating the reverse, however.

The HON. SECRETARY suggested that the effect of dust was often mistaken for halation.

Mr. FRESHWATER had found proportionately long exposures less likely to yield halation than short exposures, and instanced some photographs taken through a conservatory and a couple of rooms. In some which were under-exposed the far window was almost blocked out, while in the case of fully exposed plates everything was sharp; there was detail throughout, but no halation.

The HON. SECRETARY said there were three distinct stages in the production of halation. First, with a short exposure, when you get halation; second, a good or proper exposure, when you can develop the image before attacking the halation deposit; and, third, when the exposure has been still longer, where the halation is right through to the front and develops up with the image.

Mr. HARVEY suggested that the yellowish colour of the film would prevent a certain amount of halation.

Mr. WELFORD said, if the thickness of the glass is responsible for the halation, how was it that in photo-mechanical work, where plate glass was often used, they avoided halation?

Mr. RAPSON, speaking of the amount of silver in the film, said his experience showed that the greatest halation occurred with plates richest in silver.

Mr. DRAGE suggested that the new stripping film coated on paper would probably be free from halation.

Mr. WELFORD did not think the cause of halation was known. The very fact that films are subject to halation is a proof that it did not rest altogether with the glass. There might be more in the spreading of light in the film. In answer to a remark, he did not consider that halation could be avoided by the use of a yellow screen.

Mr. RAPSON'S experience was that yellow screens lessened the chances of halation to a certain extent.

BRUSSELS EXHIBITION.

Mr. WELFORD gave a short account of the Brussels Exhibition. What struck him was the success of the British and American exhibitors. He was of opinion that they only attempted what could be rendered by photography, while Continental photographers had tried to get effects it was almost impossible to portray. Continental photographers had a lot to learn in framing and mounting.

Mr. ATKINS showed slides on Hill-Norris dry-collodion plates from drawings, drawing attention to the clearness of the film.

PHOTOGRAPHIC CLUB.

APRIL 15,—Mr. J. E. Hodd in the chair.

A circular letter was read from Mr. A. Mackie, asking for a subscription for the Traill Taylor Memorial Fund.

Mr. Nesbit showed some of the film negatives which he had made on his last visit to Paris.

Mr. Hodd passed a negative round which had been intensified, but did not yield a good print upon ordinary gelatine paper; he showed a second print on the Ilford special P.O.P. for thin negatives, which was better.

Messrs. Bridge, Foxlee, and Nesbit, however, agreed in thinking that a print at least as good could be obtained on albumen.

Mr. Isenthal promised for the 29th instant to give some information upon the X rays in connexion with medical work; he also promised to bring to the meeting one of the instruments used to make hidden matter visible.

MANCHESTER PHOTOGRAPHIC SOCIETY.

APRIL 9.—The President (Mr. H. M. Whitefield) in the chair.

The evening was devoted to a lecture by Mr. N. LUBOSHEZ, of the Eastman Photographic Materials Company, on

SUCCESSFUL PORTRAITURE AND PLATINO-BROMIDE PRINTING.

Mr. Luboshez took the latter subject first, that of platino-bromide printing, and gave his hearers a most interesting description of what that paper is. The paper is coated with an emulsion similar to ordinary bromide paper, *i.e.*, bromide of silver, the difference being that in bromide paper emulsion there are less silver salts in the gelatine than the platino-bromide, which has more in proportion to the quantity of gelatine; consequently, whilst being richer in silver, the image is still on the surface, and is absolutely matt. The lecturer showed that it was suitable for large or small work, by exhibiting an almost life-size three-quarter length enlargement of a lady, as well as several examples of small work. The surface of the paper takes colour or pastel well, and is very pleasant to work upon. In the case of negatives with excessive contrasts, Mr. Luboshez gave many examples of dodging in order to secure harmonious results; and for development he advises the standard ferrous oxalate without the addition of bromide, but with a proportion of old developer. The effect of this developer is to give pure black to white with good half-tone and gradation; it builds up the image gradually, the shadows first appearing, then the half-tones, and, lastly, the detail in the high lights. It also has the advantage of not developing a correctly timed print further than the right stage, being in this respect unlike amidol, metol, hydroquinone, &c. After fixing, the image can be toned to a beautiful brown by immersion into a solution of alum, 1 part; hypo, 10 parts; and water, 80 parts, which should be gradually raised to boiling point; the print is then taken out and washed as usual. Mr. Luboshez then proceeded with the second part of his lecture on successful portraiture. Many professional photographers, he said, were working upon wrong ideas in regard to the lighting of the sitter. They have a strong top and side light on the face of the model, and, in order to reduce the shadow thus formed, proceed to place a reflector on that side, which simply does away with all modelling by flattening and distorting. Several examples were illustrated on the blackboard of this falsity in lighting. It is a fallacy to say that the reflector cannot be done without, however deep the shadow may be, which fact was demonstrated by the lecturer inviting the President to step forward, when by means of a muslin diffuser, between the light and the head, it transformed the harsh root and whitewash lighting into soft and harmonious modelling. Mr. Luboshez advises a full exposure, always observing the maxim to expose for the shadows, and let the high lights take care of themselves; the subject of development was then proceeded with. If the exposure is unknown, it is advisable to commence with development, and, if the exposure has been sufficient or over-timed, bromide can be added by degrees, and, if much over, the plate may be put into a weak solution of bromide of potassium about 1 part to 100 of water, and development then proceeded with. If, on the contrary, the plate has been under-timed, there is far more chance of obtaining detail in the shadows than if there had been a strong developer with the addition of bromide.

Camera Club. — If all photographers were obliged to work under the conditions voluntarily, and necessarily adopted by Mr. R. B. Lodge, we fear that this art would very quickly die a natural death. Mr. Lodge is a naturalist as well as a photographer, and this particular branch of natural history, to which he has devoted many years of his life, is

THE STUDY OF BIRDS.

In this interesting paper, read before the Camera Club on Monday, last week, he fully explained the manner in which he shot at our feathered songsters without hurting them, and how, at the same time, he gained for science much valuable information as to their ways and doings. He illustrated his remarks with a series of photographs, many of which were beautiful pictures, and some of which were taken under extraordinary conditions. He uses the telephoto lens almost exclusively, and better examples of its usefulness in obtaining large pictures of distant objects were never exhibited. But, even with this aid, he was obliged to use expedients in approaching his quarry, which would deter most photographers from such work; he, therefore, need have no fear of many rivals in wild-bird study with the camera. He envelops himself in a huge bag, camera and all, and thinks little of crawling through ditches and over marshes for hours in the endeavour to stalk his game. By this artifice, he has been able to photograph birds of the most timid character while sitting on their nests or tending their young, and has laid up a store of pictures which would have delighted the heart of Gilbert White, as they bring pleasure to all who look upon them to-day.

ON the Thursday following Captain SPRATT read a paper on another kind of hunting, on which he had used the camera to great advantage. Its title was

ELEPHANT-HUNTING IN THE NEPAUL TERRAI,

and it was copiously illustrated with Kodak pictures, taken mostly from the back of one of the animals of which he discoursed. Commencing with a map of the north-east corner of India, the lecturer pointed out the stretch of country covered by the hunting operations, and then proceeded to give a succinct account of the manner of hunting the wild elephant adopted by the Nepaulese. A hunt of this description is organized by the Maharajah of the district every four years or so, not oftener, or the forest would be denuded of big game. The hunt takes place solely for purposes of sport; there is nothing commercial with regard to it. The Maharajah, when he goes a hunting, is accompanied by about 3000 attendants, consisting of hunters, coolies, and servants, and takes with him about 300 elephants, of which a small proportion are trained fighters. This small army of men is kept under an admirable system of control. There is no harsh treatment, plenty of smiling faces, and every one is liberally paid and rationed. The country is very beautiful, and, according to the views shown, consisted mostly of valleys just beneath a range of mountains, well watered by rivers and smaller streams. In several pictures the crowd of natives had a strange appearance, from the circumstance that each man carried on his back a kerosene tin to hold water. When a convenient spot for camping is reached, a long line of outposts is sent out to keep the wild elephants from getting too far afield, and there was some excitement one night when the camp was aroused by the firing of guns from some of these watchers. It transpired, on the following morning, that a large bull elephant had escaped through the cordon, and in a few hours' time the hunters were astir to follow in his track. Footprints of the great beast were plainly visible in the soft earth, and in many of these the additional print of a tiger's pad was seen, thus showing that there was another hunter on the war path. Each one of the party carried a heavy pistol to fire in the air to scare the elephant, or to use in a more direct manner should he show fight. The three hundred elephants moved into the forest, and the hunt began, silence being observed by all. At length the bull was sighted, and then all was noise and bustle, every one pressing forward in hot pursuit of the great creature, who was occasionally seen, as openings in the jungle permitted, 150 yards ahead. The chief object now became to run the elephant until he stopped to breathe. After a short time he was brought to bay, but before he could be attacked he again started off at full speed. Again he came to a stop, charged one of the pursuing animals and knocked him over. A third time he faced his many enemies, with a couple of hundred elephants crowding round him, but not one among them having the pluck to attack. At last a well-known fighting elephant was brought up, and he too turned tail, apparently knowing that the wild bull was more than a match for him. A second fighter was then called upon, and then the combat began, the two elephants charging at one another with heads down, and their skulls coming into collision with terrible thuds. At length the wild elephant, with loud trumpeting, acknowledges his defeat, and it now only remains for him to be captured and secured. With this purpose in view he is driven towards water, which on this occasion was found within about one mile from the place where the fight occurred. The poor beast drank deeply and long, and douched himself with spray, becoming so forgetful of his situation that he allowed the natives to crowd round him and hobble his hind legs. Being at length somewhat refreshened, he attempted to charge his enemies, but found that this was impossible. Two big elephants pushed him forward, and he was finally secured to a tree with five or six animals left to guard him, and to bring him into camp the next morning. By kind treatment he is in a few weeks subdued, and in as many months is quite under control. It may be supposed that captivity is not a very unpleasant fate for the elephant, for he is generally well treated, and occasionally, if of fine stature has little to do, beyond carrying some Eastern potentate in a gilded howdah on his broad back. Colonel Spratt is one of the very few Europeans who have had an opportunity of witnessing this magnificent form of sport, and he must be congratulated on his success in obtaining so many photographic souvenirs of such a unique experience.

Hackney Photographic Society.—April 14, Mr. W. A. Hensler presiding. —Members' work was shown by Messrs. Gosling, Hindsley, Dunkley, Carpenter, and Hensler. Mr. W. THOMAS read a paper on

PICTORIAL WORK WITH THE HAND CAMERA,

in the course of which he laid great stress on the following points: 1, To try for success in technique first, and for this purpose it was advisable practise to

time exposures until the requisite experience was attained; 2, the subject was of minor importance, and pictures could be made from very small material; 3, for pictorial work very little detail was needed. The form of hand camera was immaterial, but it should possess a good lens, of not too short a focus—say, five inches and five and a half inches for a quarter-plate—with the available working aperture as large as possible. Two large finders (not less than one inch in diameter, and, preferably, one and a half inches) should be provided. The view in the finders should be adjusted to exactly correspond with the amount thrown on the plate by the lens, and all extraneous subject be blocked out. The camera should have a good shutter. The precise form did not matter, but the speaker used the Thornton-Pickard, time and instantaneous. Dealing with the pictorial part, Mr. Thomas showed, by means of diagrams, the effect of lines and masses of light and shade in composition.

North Middlesex Photographic Society.—April 13, Mr. MacIntosh in the the chair.—Mr. MUMMERY passed round two negatives on Lumière's plates, one developed with a normal developer and the other with considerably more pyro, and asked the reason of the fog present. Beyond that it was not chemical fog, no satisfactory reason was arrived at. This led to a discussion on green fog in which Messrs. Child Bayley, MacIntosh and others took part. The Secretary passed round some prints produced by Mr. G. H. Moss's process on Whatman's and Joynson's drawing papers. Mr. MACINTOSH said the process gave very good results, but was very extravagant in silver. Mr. ADDISON asked how to fix plumbago on a bromide print used in touching up. Mr. BEADLE recommended exposing it to the steam from a kettle over a spirit lamp, which softened the gelatine and enabled it to hold the plumbago.

Aintree Photographic Society.—The Society were fortunate in having decided upon Saturday, April 18, as the date of their first monthly excursion of the season. The weather was delightful, quite a summer's day, and the drive of over fifteen miles through Orrell, Litherland, &c., to Crosby Park and Hall, and home by way of Ince village, Ince Wood, Sefton, &c., was very much enjoyed. Mr. W. Blundell met the party at Crosby Hall, and escorted most of them through the rooms, the other members scattering themselves over the extensive park with cameras. Over fifty negatives were secured. The next excursion is fixed for Saturday, May 16, to Knowsley Hall, by permission of Lord Derby.

Birmingham Photographic Society.—Tuesday, April 14, Mr. William Jones in the chair.—Subject:

THE RETINA AS A PHOTOGRAPHIC PLATE,

by Dr. I. O. Tunstall, M.D. Lond., President of the Sutton Coldfield Camera Club. Dr. Tunstall, in his opening remarks, said: "It has long been my feeling that a lecturer, in any attempt to bring intelligibly before an audience a subject of a special and technical character, does well to divide his subject very clearly into headings, and to resort, wherever practicable, to explanatory diagrams." Taking first the subject of "The Eye as a Camera," the lecturer said: "A camera in its simplest form is an optical contrivance by which, in a dark-closed chamber, an image of objects, external to the chamber, is projected on one of its walls. Even a lens is not essential, for it is possible that images should be projected upon one of the walls through a minute aperture unprovided with a lens; but, in our ordinary acceptance of the term, photographic camera, we include a lens, or system of lenses, a mechanism by which the distance between a lens and the back wall of the camera can be decreased or increased, *i.e.*, the focussing mechanism, and finally the specially prepared surface, ground glass, or sensitive plate, upon which the image of external objects properly focussed are to fall." Diagrams were used to show the optical principles of the formation of the image in a camera whose sole refracting image is a single bi-convex lens. The eye is a very complex camera. Instead of consisting of one or more simple bi-convex lenses interposed between media, which are the same on either side of each lens (the external medium in our photographic camera being always air), we have a series of refracting surfaces, and no fewer than three media. All rays of light that reach the retina must pass through cornea, aqueous humour, lens, and vitreous humour, and at the junction of each surface with its contiguous medium. Mathematicians have shown that, if the refractive indices and radii of curvature of the different media and surfaces are ascertained, then a complex optical system, such as that of the eye, can be reduced to a simple diagrammatic system of two media, and the curved surface separating them. But there is another difference also besides the difference in the complexity of media and curved surfaces between the eye and a camera; there is the wonderful accommodating mechanism of the eye essential for focussing purposes which can never be imitated by the focussing mechanism of a camera. In the eye the lens is not made of hard glass of which the curvature of the surfaces cannot be altered at pleasure, but of softish living tissue contained in a perfectly transparent capsule, whose margins are attached near a muscular ring that goes right round one sector of the eye. When this little muscle acts, it loosens the capsule (or suspensory ligament, as this outer part is called), and, the elasticity of the softer lens substance coming into play, the lens bulges, and so accommodation is effected for near objects. Accessory to these essential parts of the optical mechanism of the eye is the beautiful curtain, appropriately called iris, which shuts off peripheral rays, and keeps the image on the retina "sharp." We will now pass on to the consideration of that sensitive membrane, the retina which, without doubt, subserves for the organism a similar function to that subserved for the photographer by the sensitive plate. When I tell you that in its thickest part the retina is not more than $\frac{1}{50}$th inch in depth, you will be prepared to marvel at the complexity of its structure, even before one word is said explanatory of the functions of its various parts. The retina consists of seven layers, but we shall observe more particularly the layer of rods and cones, which structures, connected as they are through the other layers with the "nerve fibres," form the ultimate terminals of the optic nerve, and are without doubt the bodies in which visual impulses are first generated. The layer of rods and cones is the outermost of the seven, and light falling upon the retina must pass through the other layers before it can act upon these bodies. The rods and cones deserve a little more careful study than we can devote to the other layers. Each rod when observed under a sufficiently high magnifying power is seen to consist of two parts, an inner and an outer. The outer is absolutely cylindrical, whilst the inner is somewhat fusiform. Both appear to be slightly grooved longitudinally; but, whilst the inner is colourless, the outer is, in the natural state, tinged a pinkish purple by a colouring matter diffused through its substance. The colouring matter is known as visual purple. The cones, like the rods, are clearly divisible into two parts or segments, outer and inner. The inner are vinucated cones, very similar in shape to conical bullets, while the outer are regularly tapering elongated cones. The inner segment is marked longitudinally, the outer transversely, giving the appearance of being composed of superimposed discs. The distribution of rods and cones is not the same in all parts of the retina. On the greater part of its area the rods are much more numerous than the cones, the proportion shown in any vertical section being about three rods to one cone. Touching slightly upon the chemistry of photography, the lecturer proceeded to show very clearly how the retina could be compared to a photographic plate. It is possible, he said, by means of the visual purple to photograph a bright object on a retina, and to "fix" the photograph by a solution of potash alum. In conclusion, the inference to which the argument tends, even if it does not establish it in an absolute proof, is this, that just as in photography a sensitive plate is employed whose important constituents are photo-chemically active substancers and sensitisers, so, in vision, phenomena occur which are curiously similar to the first series of those reactions by which the "light pictures" we call photographs are produced; for in the eye we have a sensitive plate, the retina. We have absolute proof that light can form pictures on this living sensitive membrane, and we have good reason to believe that in ordinary vision the stimulation of the terminals of the optic nerves, *i.e.*, the rods and cones, is brought about by chemical changes occurring in photo-chemically active substances contained in the outermost layers of the retina, the photo-chemical activity of one of which substances, viz., the visual purple, being easily demonstrated, and its *rôle* in visual phenomena being either that of a sensitiser or substance of primary importance as regards vision *vid* the rods.

Darwen Photographic Association.—April 16, the President (Rev. Henry Irving) in the chair.—Mr. T Mitchell, of Blackburn, was the motive of inciting a very pleasant evening.

PLATINOTYPE,

being the subject of his demonstration, was dealt with in a most presenting manner. The demonstrator, in his introductory remarks, mentioned Mr. W. Willis as being the inventor of the process, and gave a brief account of the history and chemical nature of the paper. For the benefit of any member who cared to make his own paper, seeing that the patent rights of the Company have now expired, the following formulæ were given, viz., No. 1: Ferric oxalate, 600 grains; distilled water, 5 ounces; oxalic acid, 40 grains. No. 2; Chloroplatinite potassium, 400 grains; distilled water, 5 ounces. Of No. 1 solution take 22 drachms; No. 2, 24 drachms; water, 4 drachms. The paper, after being sized according to the tint required (*i.e.*, gelatine for bluish black, and starch or arrowroot for brownish), is floated face downwards in the above solution for not more than three minutes, then dried in about 100° Fahr., care being taken not to exceed this temperature, otherwise fogged prints will be the result. He then exposed a number of prints by the aid of a platinotype printing lamp, as advertised by the Platinotype Company, charged with about thirty grains of magnesium powder, and also two cylinders of compressed oxygen and hydrogen gas, and Duplex patent regulator. The frames were placed about six inches from the flame until the magnesium was burnt away, after which Mr. Mitchell proceeded with the development, using the salts as sold by the Company on account of producing better half-tones, urging his audience emphatically upon the importance of having the developer at a *minimum* temperature of 60° and a *maximum* of 100° Fahr. On account of the vigorous action of the developer, Mr. Mitchell drew attention to the manner of development, which was better done by taking hold of the paper at each end and drawing it face downwards through the solution once. This, he said, was to prevent the adhesion of air bubbles on the picture, and to be more certain of damping the whole surface without leaving dry patches, as the action of the developer is so rapid that, by the time the manipulator notices the defects, it is very often too late to rectify. In addition to this, it allows a little more time to examine, and, with three immersions, the picture is generally about developed. After this, the prints were transferred to three baths of hydrochloric acid and water, one to sixty, and allowed to remain five, ten, and ten minutes respectively, then washed for about twenty minutes in running water, the whole operation of printing, clearing, and washing being complete in much under an hour. Another point which the demonstrator strongly emphasised was the use of pure hydrochloric acid during the clearing process, strongly advocated the rejection of the third bath immediately it assumed the least trace of slowness, this being essential if permanent prints are to be the result. Many prints were developed, ranging from quarter-plate up to 10×5. By making the following solution slightly alkaline, warm tones may be produced. Potash soda or the carbonates of these alkalies may be used, but on no account in larger quantities than just sufficient to turn red litmus paper blue (ammonia unsuitable): Oxalate of potash solution, normal strength (*i.e.*, 1 pound of oxalate dissolved in 54 ounces of water), 1 part; water, 2 parts. A number of prints were exhibited showing their different qualities and defects, viz., prints obtained with acid developer, alkaline developer, old developer, the defects of over-printing, and *vice versâ*, damp paper, also development with mercury, and brush development with glycerine. The lecturer was thoroughly at home with his subject, and treated it in a very interesting and attractive form.

Liverpool Amateur Photographic Association.—April 16.—Mr. W. LAMOND HOWIE delivered a lecture before the members of the Association and their friends, entitled,

FROM MOUNT BLANC TO THE MATTERHORN.

The lecture was illustrated by a number of lantern slides from negatives taken

by the lecturer, the route traversed being the French Alps, round Mount Blanc into Italy, Aosta, Milan (the chief attraction here being the beautiful cathedral), the Italian lakes, and Switzerland. The concluding slides showed some magnificent views of the Matterhorn.

Moseley and District Photographic Society.—Mr. Myersward, surgeon, was enrolled as a member. Mr. FRED PILDICH, Hon. Secretary of Aston Photographic Society, delivered a lecture entitled

WHY?

The lecturer explained that his intention was to give the ladies and gentlemen present an insight, as far as his ability and time allotted would allow. When he (the lecturer) first saw a plate developed, he thought it was wonderful. You take a drop of solution No. 1, and put in measure, then slash in some No. 2, and a few spots from a bottle No. 3, and, the plate having been put in a tray, the developer is flowed over, and in a few seconds the image begins to become beautifully evident. That seems easy enough. Hang it! I could do that. But, upon thinking it over, the lecturer said he saw that it was evident that the gentleman he was watching developing knew why he mixed his developer as he did, and knew why, when development was about half completed, he added some No. 1, &c., and he (the lecturer) came to the conclusion that, if he was to do anything at photography, he must know why he did it. Treating upon developing, the lecturer explained how, according as he understood it, the bromide of silver, &c., film upon exposure to light was converted into a sub-bromide in those parts. The lecturer explained by symbols how the developer composed of pyrogallic acid, water, and ammonia. The pyrogallic acid, being a greedy substance, would take the oxygen from the water, thus leaving the hydrogen free. But the hydrogen was of a fickle nature, and, after being engaged to the oxygen, which has gone, it must find another partner—hydrogen is no bachelor—and it joins the ($2NH_3$) ammonia, and makes another composition of ammonia ($2NH_4$). But where the light has acted upon the silver bromide and made it a sub-bromide, which is a less stable compound, the now altered ammonia is on the look-out for a partner, and the sub-bromide, which is a weak maid, is attracted by the ammonia, and falls, leaving the silver as the metal. Here, then, we have the developed negative. But, where the light did not act on the silver bromide, the ammonia does not attack it, and it remains. This is the creamy substance on the back of the unfixed plate. Hyposulphite, or, more correctly, thiosulphate, of soda is the agent used to clear or dissolve away this stabler bromide. In fixing, if a very weak solution of hypo were used, the sub-hyposulphite of silver is formed, but this is only soluble in a strong solution of hypo, so the plate would not fix, for the weak solution would not dissolve this sub-hyposulphite of silver. So we have to use a strong solution four or five ounces to the pint of H_2O. The bromide being dissolved away, the metallic silver is left in suspension in the gelatine film in a very fine state. The lecturer then explained the two developers, ferrous oxalate and hydroquinone. Hydroquinone was very nice and easy for a beginner, but when the tyro began to fell his way, and know why he did certain things, he would advise pyro and ammonia. Hydroquinone gives pretty negatives. Pyro ammonia gives good and brilliant prints. There is the difference. The lecturer closed, hoping that all would take a greater interest in the scientific side of photography, and more thoroughly learn and investigate these things, that he may be better enabled to develop his picture. The lecturer stated he would be only too glad if there was discussion, and would be pleased to answer, to the best of his ability, any question raised. Nobody else making a move, the HON. SECRETARY (Mr. Fred Coop) said that he must put in a plea for the artistic side of photography, and wished all present to understand that all this knowledge of the symbols and chemical equations was not necessary for the production of good negatives and good pictures. He advised them not to be discouraged because they had not the profound knowledge of the lecturer on these, to them, chemical hieroglyphics. Many of the best picture-makers did not know these things, and said they were quite unnecessary. If you had the artistic perseption, and went out and saw a lovely view, beautiful massing of light and shade, and exposed your plate as experience (not mathematical, or chemical equations) had taught, you would be correct, and came home, you would have an opportunity or chance of producing a good picture; but, if you only have the scientific knowledge, you, when out at nature, would not perceive and appreciate the wonderful massing of light and shade and the beautiful composition and graceful lines, and should, in all probability, take an inferior view, and perhaps make a good technical negative. But you would not have had the chance to make the artistic picture the other had, and could only perchance show an inferior view. No doubt, if you can know some of the scientific side, it will help you, but to give pleasure to young and others you must have the artistic. Mr. RENNIE stated that the science and art of photography were only made possible through the energies of scientific investigators and discoverers, where would photography have been had they not helped? Therefore he would put in the plea for the scientific side of photography. Mr. FRED PILDICH then replied that photography had many branches in science, and was being used in so many different scientific directions, that, of course, they would have to be considered. He owned it was not absolutely necessary to understand in all cases "why?" but still he thought photographers would do better work and get better results by that knowledge. He was glad there had been discussion, it showed interest had been raised, and he thanked them cordially.

Newcastle-on-Tyne and Northern Counties' Photographic Association.—The ordinary monthly meeting was held on April 14, Mr. John Watson (Vice-President) in the chair. A resolution, proposed by Dr. Blacklock, that the Association adopt a scheme of competitions open to amateur members, was unanimously adopted. Details to be settled by the Council at next meeting. Mr. T. O. Mawson then read a paper upon

CARBON OR AUTOTYPE PRINTING,

afterwards giving a very interesting and successful demonstration of the process. [This will appear in our next.]

Oxford Camera Club.—The last meeting on April 13 was devoted to a lecture by Mr. Nahum Luboshez, of the Eastman Photographic Materials Company, on

PLATINO-BROMIDE PAPERS AND PORTRAITURE.

Mr. G. W. Norton occupied the chair. After pointing out the difference between this bromide paper and an ordinary negative, the lecturer gave the following as axioms, by following which good prints could be relied on with pure blacks and pure whites: 1. The developer to reduce all the sensitive material on which light has acted. Unless this is done, the blacks will not be pure, but tend to yellowness or muddiness. 2. The developer not to stain, or the whites will not be pure. Hence, not only pyro, but strong alkalies are to be avoided, as these tend to yellow the gelatine film. 3. The developer must have a constant composition, so as to ensure identical results at different times. He strongly recommended ferrous oxalate as fulfilling all these conditions, and also because the image comes up gradually, so allowing correction if anything is wrong. One part of iron solution to four of oxalate solution gave the strongest developer and blackest tones, but as low as one to ten could be used for very soft effects. The blisters often occurring in bromide-paper work were noticed, and shown to arise either from great differences of temperature or too great force of water. A frequent source of blisters was a newly made, and therefore ice-cold, fixing solution. As to portraiture, he considered the usual practice of photographers of using a reflector on the shaded side to lighten the contrast quite wrong. The effect of the reflector was to throw into light the parts that ought to be in deepest shadow, and hence give a false modelling to the face that destroyed true likeness, and entailed an enormous quantity of retouching to give an appearance of truth. A far better plan was to use a diffused light, as through tissue paper or ground glass, which lighted up the shadows without altering the modelling, just as shadows in a landscape are best photographed on a cloudy, not a bright, day. He illustrated this point most effectively by a wetted handkerchief on a stick, held between the light and the face of the sitter. The direction of the light was also extremely important, as a sphere could be made to look either more or less curved than in reality by alteration of the lighting, hence the sometimes lengthened and sometimes broadened faces in ordinary portraits. The development should be kept well under control, preferably by adding water. If, however, over-exposure was found, bromide could be added when the detail was out, so practically making the plate slower, and allowing density to be given.

Photographic Society of Ireland.—April 10, Mr. Alfred Werner (Vice-President) in the chair.—Mr. V. E. SMYTH delivered a lecture, entitled

THE ENGADINE,

which was profusely illustrated with very excellent slides, the majority being technically perfect, while a great number were very pictorial renderings of incidents and places visited by the lecturer during his journey. Mr. Smyth, in the course of his remarks, said he was indebted to his friend and co-traveller, Mr. Brown, for some of the slides; the majority were, however, of his own production. Starting from Dover, and crossing to Calais, of which two places some very good snap-shots were shown, the traveller passed on to Laon, and in this city some perfect bits of the cathedral were obtained, and some interesting historical matter, were lucidly described. A very amusing description of a battalion of French soldiers was given, and which the lecturer entitled "Going to the Canteen." A good deal of fun was produced by the introduction of a slide showing the return from the canteen, which consisted in a slide from same negative as above, being exposed to heat while still wet, causing the gelatine to run, the effect was ludicrous. Rheims, the centre of the Champagne district, we next visited, and some beautiful views of this place were shown, notably one of the Ancient Roman Arches, a very beautiful structure. Mr. Smyth must be credited with the excellent way in which clouds had been so successfully introduced. In Switzerland many places were visited, the principal being Berne, Interlaken, Thun, Chur, St. Moritz, and Pontresina. From all these places Mr. Smyth brought home some very pictorial records, and that this gave so much pleasure to an attentive audience is hardly surprising. Rarely have we seen anything better shown before this Society. Mr. Smyth's success may, in a measure, be attributed to his using a twin-lens camera, and thus was able to compose the picture more accurately than if using an ordinary finder; his works certainly favours the use of this style of hand camera if anything like success is desired.

Correspondence.

☛ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

PROCESS PRICES.

To the EDITORS.

GENTLEMEN,—Some misconception having arisen as to the effect of the resolution passed at the meeting of the various firms engaged in process engraving held at Anderton's Hotel on February 24, I am directed by the executive of this Association to ask you to be good enough to afford me the widest publicity possible to the statement that the rates agreed upon at that meeting were not to be registered as *standard* rates but as *minimum* rates, below which none of these firms represented at the meeting were prepared to undertake the production of work in the future.

It in no way binds them to undertake all or any classes of work at rates

as low as the *minimum*; in many cases the surrounding circumstances will necessitate charges considerably in excess of these *minimum* rates.—I am, yours, &c., GEORGE E. HOLLOWAY, *Secretary*.

47, *Lincoln's Inn-fields, April* 20, 1896.

THE ARTIGUE PROCESS.

To the EDITORS.

GENTLEMEN,—In much of the correspondence and articles on carbon printing without transfer there is a lamentable and persistent tendency to confuse the issues, and Mr. Foxlee's communication in the current number of your JOURNAL is no exception to this tendency. He informs us with the air of a new fact that the Artigue process must not be confounded with that of Pouncy or the other methods described by me. Why, that is what I have persistently insisted upon all along, in the face of the extraordinary perversity of some writers on this subject! In 1893 I brought the Artigue process prominently forward at the Conference which I gave at the Salon. The beautiful results which I showed were pronounced by the theorists to have been made under special conditions, not easily to be followed. Then the battle of confusion began, and, although at the succeeding Salon the most perfect results were shown in the pictures by Captain Puyo, the fact that they were carbon prints developed from the front never dawned upon those who, like "Dogberry" and Mr. Foxlee, say that "tolerably good results" can be obtained by this method under certain conditions.

Mr. Chapman Jones and his supporters will not accept the challenge which I made in your columns a few weeks back, and so allow judgment to go by default. In plain terms, they prefer the shelter of theoretical verbiage to a straightforward way of settling a contested point. It would be much more interesting if Mr. Foxlee would take up this challenge, for "Dogberry," in his anonymous position, must of course be allowed to write any amount of irresponsible vapourings, and cannot seriously be reckoned with.—I am, yours, &c., ALFRED MASKELL.

Ilfracombe, April 20, 1896.

PHOTOGRAPHY IN THE ILLUSTRATED PRESS.

To the EDITORS.

GENTLEMEN,—I think, with you, that it is high time that a protest should be uttered against the class of illustrations appearing in many publications, which depend on photography for the means of filling their pages with pictorial matter.

And I exult that you have been the first (as far as I know) to couch your lance and tilt thereat. Your "Ex Cathedrâ" remarks are to the point, and I, too, feel confident that no sensible man of the world will quarrel with your objections, but trust that they will be taken up, increase in volume, and swell into a purifying flood.—I am, yours, &c.,

7 *and* 8, *Park-street, Anlaby-road, Hull.* W. BARRY.

PHOTO-CHROMOSCOPES.

To the EDITORS.

GENTLEMEN,—With reference to the subject of Mr. Wall's letter on p. 255, I have not thought it necessary to mention Herr Zink, because my date of record for the invention antedates his, and his work is therefore of interest only as an undoubtedly genuine case of reinvention. What either of us did before our dates of record cannot be taken into account. Herr Zink's date of record (by a public exhibition), of a comparatively crude invention, is antedated by my application for a patent covering not only the same thing, but a far better construction—more powerful, more compact, more convenient, and stereoscopic. It is impossible to say when Herr Zink's work would have been put on record (possibly not at all) if he had, like myself, waited to make such important improvements.—I am, yours, &c., F. E. IVES.

24, *Southwick-street, Hyde Park, London, W., April* 17, 1896.

ASSISTANTS AND THEIR GRIEVANCES.

To the EDITORS.

GENTLEMEN,—The grievances of the photographic assistant have lately been ventilated in your columns with persistent and unfailing regularity; for this privilege assistants owe a debt of gratitude to the late Mr. Traill Taylor, and also for the good advice, sympathy, and encouragement he constantly gave them in this JOURNAL. I think I am expressing the feeling amongst assistants when I say that they fully appreciate the continuation of Mr. Traill Taylor's kindly efforts on their behalf, and are not indifferent to the fact that these columns are still open for the expression of legitimate grievances. The publicity recently given to the complaints of assistants has gradually changed the general opinion on the subject. At one time it was thought that the photographic assistant could not possibly have a grievance, that his life was passed in a state of heavenly calm, undisturbed by a single pang in the happy hunting-grounds of the glass house and the dark room; but now, even the most optimistic printer suspects there is something "rotten in the state of Denmark" when he is compelled to work for 1*l.* a week in a glass house having a summer temperature of 110° in the shade, and a winter of somewhere near zero; and the most callous employer feels some shame at putting his operator to work in a dark room compared with which the atmosphere of the Black Hole of Calcutta would be a welcome change.

It can no longer be denied that the grievances of assistants are both pressing and real, and something more than the outpourings of a discontented agitator, or grumbling ne'er-do-well. Having admitted the reality of grievances, it remains to accurately specify what they are and then to seek for the remedy. In many instances the simple statement of a grievance is sufficient, and if laid before an employer in the right spirit he will instantly apply the remedy. The publication of grievances has already done something in this direction even in the firm indicated by a "North Wales Operator," and I have no doubt that in many other instances it has had a beneficial effect on the treatment of assistants by employers. Much, however, remains to be remedied, and this can only be done by combination and mutual trust amongst assistants. A want of trust is the chief difficulty, as will be shown by a case I will relate. A short time ago the following appeared in the *Clarion*.

"L. C. is a young girl working for a photographer as a finisher of photographs, for 12*s.* per week. She estimates her employer's profits at 100*l.* per week! The work is exceedingly trying to the eyesight, and carried on in a small, close, ill-ventilated room in which many other girls are working. No talking is allowed, and one girl is set as a spy to watch the others. Not content with ruining the health of the girls who slave to provide him with his enormous wealth by compelling them to breathe the vitiated atmosphere of his miserable dens of workrooms, he must also make their lives still more dreary and monotonous by forbidding them to indulge in a little pleasant conversation. What system of slavery could be more complete?"

"Julia Dawson," a member of the staff, appealed for help to remove this young girl from her position. I wrote to the *Clarion* promising to do what I could to bring the case of L. C., or others, before the photographic world. My address was published along with a special request by "Julia Dawson" to all unjustly treated assistants to write to me; yet in spite of this special appeal neither L. C. nor a single assistant took the trouble to communicate with me. Such apathy prevents any serious attempt being made to redress long-standing grievances. It was quite impossible to deal with the case of L. C. because of a lack of evidence. If L. C. had come forward to verify the facts stated, it is clearly a case for the workshop or factory inspector, whose duty it is to see that workpeople have properly ventilated rooms. I fear it is a dread of consequences which prevents L. C. and others from coming forward and openly stating the injustice under which they suffer. Nothing, therefore, can be done to help the sufferers, until some are bold enough to come forward to state what are their wrongs and who are the wrong-doers.—I am, yours, &c. JOHN A RANDALL.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

RECEIVED:—WELLINGTON & WARD; J. W. MOORHOUSE; E. MENTOR; B. G. DAVIS; "ONE OF THE DUPES;" W. BENNINGTON; and others. In our next.

DEVELOPING.—W. B. The bromide acts as a retarder, the alkali as an accelerator, and the pyro as the developer.

STAINS ON INTENSIFIED NEGATIVES.—PYRO. We fear we cannot help you without seeing a negative. Send us one and we will endeavour to suggest a remedy.

VALUE OF LENS.—B. BROWN. The catalogue price of the lens, if the one listed to cover 15 × 12, with medium stop, is 24*l.*, less five per cent. for cash. We do not value second-hand apparatus.

STAINED NEGATIVE.—H. AYLWARD.—We are afraid it is a hopeless case, unless the stain is but slight. The only thing that occurs to us is, to whiten the negative again with bichloride of mercury, thoroughly wash, and then reblacken, using great care in the operations.

STUDIO.—T. ALSTON. By putting the background end of the studio close to the wall of the house you will lose no light, and will gain the advantage, that the high wall will stop off the direct rays of the sun at midday when they are most troublesome.

PROFESSIONALISM.—R. C. J. We think it will meet your requirements better to join the Photographic Copyright Union than the National Association of Professional Photographers. The former deal with photographers' copyright questions in an efficient manner, and that seems to be your only object.

COLLODION EMULSION.—C. A. BRITTEN. Pyroxyline suitable for emulsion purposes, whether bromide or chloride, may be obtained from Messrs. Rouch & Co., Thomas, or Hopkins & Williams. We do not expect that, with the pyroxyline, either firm supply directions for making the different emulsions.

SALE OF BUSINESS.—X. A. Z. If you bought the lease and goodwill of the business, and made no restrictions that the seller should not start a fresh business in the same neighbourhood you are without a remedy. There is no rule in the matter, it is simply a matter of agreement, and apparently you made none.

DRY PLATES AT THE CUSTOMS.—PROSPECTIVE TOURIST. As you speak a little German, if you have the plates labelled as photographic and not to be exposed to the light, you will have no difficulty on the German frontier, particularly if you carry the camera and stand with you, or have it conspicuously amongst your personal luggage.

SPOTS ON NEGATIVES.—F. RUSSELL. From the description of the spots we fear there is no remedy; you might, however, try immersion in a bath of alum and hydrochloric acid, such as is used for "clearing" purposes. If you think they are silver spots, try a weak solution of cyanide, or a solution sold for the purpose by Messrs. Marion.

SPOTTING OPALINES.—T. J. EVANS asks: "Can you please tell me the best thing to mix with the colour to spot prints before they are wetted to be put on opalines, so that the spotting will not come off when put in the water?"—A black-lead pencil is often used, so are oil colours. Special colours for the purpose are supplied by most dealers, and they will possibly be the best for our correspondent to use.

CELLULOID COLOUR SCREENS.—T. HORNER. Celluloid, or xylonite, can be had of various colours. It can also be stained, or dyed, of any desired tint if alcoholic tinctures be employed. But we doubt very much if, so treated, it would answer so well for colour screens in orthochromatic photography as collodion-stained glass plates. Celluloid would certainly arrest more light than a stained collodion film on glass.

STUDIO.—P. O'MALLY. If you object to ground glass at the side of the studio, use fluted glass; that will quite prevent the neighbour's children from seeing into the studio. Ground glass, however, will not obstruct the amount of light you seem to imagine, provided, of course, that it is kept reasonably clean. We say reasonably clean, because cleaning the glass is a thing that is but little attended to in many portrait studios.

MOUNTING.—ELPHIN says: "I should be much obliged if you would tell me through the JOURNAL which is really the correct way to mount an oblong view on a cabinet mount, *i.e.*, on the left or right side?"—As the mounts are very unsuitable for the purpose, it does not very much matter which end the name comes. Perhaps, on the whole, it will be best on the left-hand side. It ought, of course, to be at the bottom or nowhere.

A DOUBTFUL TRANSACTION.—W. A. writes: "Seeing an advertisement of a 'set' by a good firm at a low price, I sent the money for it, but have not received the apparatus, nor can I get any answer to three letters I have written. It is now ten days since I sent the money. What shall I do? The place is over two hundred miles away."—Lose no time in communicating with the Superintendent of Police in the district, giving full particulars. The thing looks very like a fraud.

CLEANING VARNISHED GELATINE PLATES.—A. WELSH asks how to get the films off dry plates that have been varnished?—Soak the plates for a day or two in water, to which a little American potash, or a little caustic soda, has been added. Then put into hot water, and the films will come off readily. It is a little doubtful, at the present price of silver, if the metal recovered will pay for the trouble, that is, if the value of time be taken into consideration.

CHEAP ENLARGEMENTS.—POPULAR asks: "What enlarging paper most closely resembles the collodion transfer, and to be equally suitable for rapid colouring, or nearly so, sizes, say, from cabinet up to 15×12, either busts or full figure? Ordinary bromide paper seems altogether too 'cold' to obtain the result desired in a cheap and effective way."—We can suggest nothing better for the purpose, if price is the chief consideration, than bromide paper. With judicious development an objectionable cold tone may be avoided.

STICKY CAMERA BELLOWS.—H. PINCHE says: "On opening my camera to-day—the first time for months—I found the bellows all sticking together, and, when separated and folded up again, it sticks as before. It is some kind of imitation leather, with, I fancy, indiarubber in its composition, by the smell. Can this be remedied?"—It is very doubtful. The only thing we can suggest is to rub French chalk well into the folds, and repeat the treatment from time to time. The best remedy, however, is to have a new bellows to the camera, as the composition covering has apparently perished.

RIVE PAPER.—M. T. writes: "Could you kindly inform me where I could obtain some Rive paper (plain)? I want a small quantity—a quire or two. Any pure paper free from acid would suit my purpose."—In reply: The paper is, we think, supplied by most dealers, or can be obtained of the agents, L. Trapp & Co., Budge-row, E.C.

TONING GELATINE PAPER.—H. C. If you cannot get such good tones with separate toning and fixing as you do with the combined bath, and are doubtful of the permanency of its results, why not try another brand of paper? There are several gelatine papers in the market that yield every variety of tone with the separate toning and fixing method.

REFLECTOR HAND CAMERAS.—GLENDALE writes: "On page 242 of last week's BRITISH JOURNAL OF PHOTOGRAPHY, in the second paragraph, you mention the fact of a 12×10 hand camera being focussed by means of a Vanneck reflector. Could you convey any idea to me as to how it works, or by whom it is supplied in this country? failing which, I should be much obliged if you could give me the number of the patent, if it has been patented."—In reply: Messrs. Watson, High Holborn, supply the Vanneck camera. What is probably meant is that the image is seen full size by means of a reflector fitted on to the top of the camera.

COLLOTYPE.—C. MILLEN. The two examples sent are a long way from being good, but they are, on the whole, not at all unpromising, considering that you have only been experimenting for a month, and have had no instruction beyond what you have learnt from what has been published on the subject. Be not discouraged, but persevere; a valuable process is not learnt in a day. It seems, judging from the prints, that the film is too hard, not sufficient moisture in it to repel the ink where not required. Possibly the plates were partially insoluble before exposure through too slow drying or being kept too long. Aim at getting them to absorb more water when wetted.

FLEXIBLE SUPPORT.—C. ANDREWS asks "What is the meaning of flexible support in carbon printing, and what is it?" and says, "Are not all carbon prints on paper on a flexible support?"—Yes, of course they are; but the term flexible support is applied to a temporary support of a flexible character, on which the picture is developed, to be afterwards transferred to another, in contradistinction to its being developed on a ridged one, such as glass, zinc, &c. The commercial flexible support is paper coated first with insoluble gelatine, and then with an aqueous solution of shellac. Before use it is rubbed over with a mixture of resin, beeswax, and turpentine, and then polished off with a clean rag. From this support the carbon image may be transferred, non-reversed, to paper or any other material.

COPYING VASES.—TERRA VASES writes as follows: "Would you kindly reply as to what is the best method to photograph a terra-cotta vase with black shiny figures on? We have to take several, and the difficulty is to get rid of the bright light reflected upon the black figures. We have to make outlines of all detail, photograph first, and, after tracing, dissolve out the basis with mercury. But this reflection destroys some of the detail and outline, and, as these vases are very ancient, we must get the drawing absolutely perfect, being for the purpose of illustrating."—It is very much a question of lighting the subjects, so that light from the bright parts is not reflected direct into the lens. The glazed portions can also be dulled by dabbing them over with putty, to which a little black pigment, such as lamp-black, has been added.

APPRENTICESHIP.—GELATINE writes thus: "I am an apprentice, having given twenty pounds' fee. The first year was chiefly spent in going with messages, the second year assisting at enamelling. Now, in my third year, I am in the studio. The master wants me to go back to the enamelling, as the enameller has left. I have refused. Can he compel me, it being my last year? Personally he is not a photographer, and, only for the kindness of the operator, I would be a duffer."—This seems to be another case of taking fees with apprentices, more with the idea of getting work done cheaply than with the view to teaching the business. We should say that our correspondent would be quite justified in not continuing to do such work as enamelling in the last year of his term. He could certainly, in a court of law, compel his master to properly teach him his business—and studio work is the most important part of it, according to the terms of the indentures—or return the money paid.

AN AMUSING REPLY.—RICHARDSON BROWN (who says he has no connexion with the party who replied to the question) writes as follows: "*Re* your paragraph 'An Amusing Reply.' In a handbook by Mr. J. Pike you will find the following recommended. Saturated solution sulphate soda, 6 to 10 drachms; water, 3½ ounces; pyro, 15 grains; and saturated solution carb. soda, 50 to 100 drops. This I have repeatedly used, and can testify to its general good qualities; and as sulphate is much cheaper than sulphite, and carb. soda (otherwise washing soda) is, in such a small quantity, absolutely without value, I cannot see but that the question asked is answered so far in a proper and businesslike way. As no size of plate is mentioned, it is fair to conclude that the writer alluded to one of the popular sizes, say, half-plate or quarter-plate, and I think, if you will take the trouble to test the sulphate, you will allow that it gives a good clear negative full of detail and perfectly free from fog. Of course, the hypophosphate is a printer's error, and it may be amusing or otherwise, but to the man who tries it probably otherwise."—As Richardson Brown's letter will probably be as amusing to our readers as the reply we quoted last week was, we give it in full. Is it not rather a pity that Mr. Brown did not correct the "printer's error" in the paper in which it appeared for the benefit of the one who put the query, instead of explaining it to us?

EX CATHEDRÂ.

To the list of those firms who supply coils, batteries, and Crookes' tubes, for experimental work with the Röntgen rays, must be added the name of Messrs. Perken, Son, & Rayment, Hatton-garden, E.C.

* * *

We are pleased to learn that the Photographic Exhibition which the Corporation of Glasgow are about to hold in the new Camphill Gallery bids fair to be of a successful nature. It will open early in June, for about four months, and will be thoroughly representative of practical photography, while colour work and reproduction processes generally will receive much attention. The scientific and other sections are being organized under competent direction, and the Exhibition will follow the lines given in the preliminary prospectus, which we quoted in the Journal of March 6.

* * *

With reference to some correspondence that appeared in our pages last September upon the subject of a "free" baby portrait scheme, started by M. Jarchy, a photographer, of Union-road, Rotherhithe, we have received the following letter from a correspondent who lives in that neighbourhood: "You will, no doubt, remember that last September several letters appeared in the Journal *re* free babies' photographs; 1000 babies were advertised for by M. Jarchy, of Union-road, Rotherhithe, to be photographed free of any charge whatever. It was said that M. Jarchy would not take any of these free photographs without a frame was purchased from him for 2*s.* 9*d.* M. Jarchy denied this. Any way, sir, he sent you a circular, and on that circular it stated that M. Jarchy was going to give three prizes—1st, gold medal; 2nd, silver medal; 3rd, oil portrait, natural size, in a frame. The last day for taking these so-called free photographs was September 15, 1895, seven months ago, and there are several inhabitants of South London anxious to know when M. Jarchy is going to hold the baby show at the Town Hall, and distribute the prizes. Might I ask, sir, that M. Jarchy may reply through The British Journal of Photography when he intends to award the prizes and hold the baby show?" We shall be happy to afford M. Jarchy the opportunity of utilising our pages for the information he is, no doubt, eager to give, and which certainly seems called for. In order to assist him in framing his reply, we refer him to pages 580 and 597 (September 13 and 20) of our volume for 1895, where he will find reproduced a circular and a letter of which he was the author. He may desire to refresh his memory with the statements and promises there made.

* * *

The New York correspondents of the daily papers inform us that Mr. Edison's vitascope was exhibited in New York last week. "A series of life-size figures were projected on a screen which reproduced dances and prize fights with startling fidelity. The splashing of waves on the seashore was also reproduced." The "vitascope" appears to partake of the nature of the screen kinetoscope of Lumière, Paul, or Acres. The great genius of Menlo Park seems to have developed quite a passion for following in the footsteps of other inventors, a sign, maybe, of greatness and genius as it is understood across the Atlantic.

* * *

Any movement which has for its object the preservation in their natural beauties of our commons and open spaces deserves the support of all lovers of the picturesque among whom photographers should be not the least prominent. The Gospel Oak Photographic Society, which has its location in the neighbour-

hood of Hampstead, has, with commendable vigilance, cast an eye upon the gardening operations of the London County Council on the north-western heights, and has felt compelled to pass the following resolutions: "That the Gospel Oak Photographic Society, while appreciating the efforts of the London County Council in the neighbourhood of Parliament Hill Fields, desires to record an emphatic protest against the gardening operations being conducted on the western portions of Hampstead Heath, and more particularly against any interference with the lake known as the 'Leg of Mutton' pond, whereby its picturesque beauty may become impaired. That a copy of this resolution be sent to the London County Council and the Vestries of St. Pancras and Hampstead, with an earnest request that the operations complained of may be at once suspended. That a copy of this resolution be also sent to the photographic press and societies in London, with a view of obtaining their co-operation in the matter."

* * *

We congratulate the Gospel Oak Society on its action in this matter; it has set an example of public usefulness which, it is to be hoped, will not be lost upon other photographic societies, whose energies might not be wasted if directed to the defence of nature against the thoughtless aggression of County Councils and similar bodies. We trust the Gospel Oak Society will be supported in their laudable efforts to save Hampstead Heath, which so many know and admire, from needless "improvement."

RECOVERING GOLD FROM OLD TONING BATHS.

A question on this subject, asked at a recent London and Provincial Photographic Association meeting, tells us that information thereon is still wanted, though the matter has been treated in these columns before with some amount of fulness; but, in view of the fact that the more modern toning baths differ materially from the old alkaline toning solutions, some little uncertainty may be felt as to how far the old methods may be available. A reference to some of the earliest editions of Hardwich's *Photographic Chemistry* will put the reader in possession of familiar modes of treatment, which are as useful now as over a quarter of a century ago. The standard method of throwing down the gold remaining from spent solutions is to add a solution of ordinary sulphate of iron. The gold is thrown down in fine powder. There is no reason whatever why the most usually adopted plan—that with sulphate of iron—should not be adopted with sulphocyanide toning baths. There is, however, this point of difference: An old sample of iron crystals that have browned by long keeping will be quite effectual; but the presence of the precipitate will be masked by the deep blood-red colour that will be produced by the oxidised portion of the crystals, a very minute quantity of a ferric salt sufficing to deeply colour a large body of liquid upon the addition of a sulphocyanide. With ferrous salts, such as the clean crystals of what is familiarly known as protosulphate of iron, no discolouration at all is produced.

Hence, where both kinds of toning solutions are employed, the disused solutions may all be poured in one waste jar, and at a suitable time thrown down. It will, however, be better to choose nice clean crystals of the iron salt, and, if the only store at hand be browned, they may be washed in a little water before being dissolved. The chief part of the ferric salt being on the surface of the crystals, it will leave a comparatively pure salt behind, which may then be used. We may again remind the reader that the gold takes a considerable time to deposit entirely, so that the precipitating vessel should be left for at least a day before pouring off the supernatant fluid. When strong solutions of gold are precipitated, however, the metal falls down in heavier and more coherent particles; but this is an unlikely state of things under the circumstances we are considering.

The precipitate thus obtained is liable to be contaminated with organic matter, with silver, and with iron, even after being well washed, as is absolutely necessary. Hence it will be necessary to get rid of them, for the double purpose of securing pure gold for re-solution and of ascertaining the exact weight. By a series of successive washings in ammonia, water, hydrochloric acid, the gold would be fit for final washing in a small filter, which should then be dried, and the filter paper with its contained gold heated to redness in a porcelain crucible and then weighed, making a suitable allowance for the weight of the charred paper.

This residue may then be dissolved by the aid of heat in aqua regia in as small a quantity as possible. The result will be a strongly acid solution of the acid chloride of gold. It will be safe to consider that the gold used will produce double its weight of chloride of gold. It may be kept in solution of the usual strength, as the evaporating down and the reducing of this solution to the crystalline form is not really necessary, and, is, moreover, a piece of work rather beyond the inexperienced photographer.

It will be quite evident, from these remarks, that the treatment of gold residues is not an extremely simple matter, like throwing down chloride of silver from the washing solutions, and the question naturally arises whether the game is worth the candle. That it is worth while to obtain all the remaining gold from spent toning baths there is no doubt, the only point is as to which of the available methods involves the least trouble consistent with the avoidance of loss of the material.

In the majority of cases we very much doubt the advisability of taking this trouble, for the following reasons:—

We have recently had the opportunity of examining a number of the credit notes of the metal refiners received by a well-known photographer, who sends all his residues away. For a series of years the price given for the silver obtained ranged from 3*s.* 2*d.* to 3*s.* 5*d.* per ounce, a value which is about twenty per cent. above the market price of pure silver. Then, about twelve months or so ago, the price allowed exceeded 5*s.* per ounce. When asked for an explanation, the gentleman in question informed us that the increased price dated about from the time when he took up P.O.P. and the sulphocyanide bath. All his waste baths were thrown in the waste hypo vat, and the gold went down with the silver. If we assume that the residues sent away included about equal parts of a mixture of chloride and burnt silver paper, and of hypo precipitate, we see that the auric argentic precipitate from the hypo alone would be worth 10*s.* or 15*s.* an ounce.

From this and the previous considerations adduced, it is a fair inference to draw that, on the whole, the best way to treat old gold baths is to throw them all into the old hypo tub; but is such a "tub" usually to be found? We have often dealt with this subject, and we may once more have something to say upon it at no distant day.

An Isochromatic Lens.—The *Standard*, one day last week, in a notice of Mr. T. C. Hepworth's lecture on "Up-to-date Photography," says, Amongst the novelties dealt with is "the true render- of colours in relationships of black and white by the isochromatic lens." Great improvements have been made in photographic lenses during the last few years, but this is the first time we have heard of an isochromatic one.

A Novel Adjunct to Photography.—Photographers as a rule, nowadays, do not make fortunes, or, at least, so quickly as not a few did in years gone by. Many now have to supplement photography by other trades or professions even to make a living. The latest we have heard of with the view to a fortune is, in addition to photography, that of telling the fortunes of others. For this a photographer was last week sentenced, at Canterbury, to two months' hard labour. Fortune-telling, on the face of it, should be a lucrative calling, seeing that it requires no stock in trade or cost for material; but, as it involves the risk of a couple of months' "hard" occasionally, it is not so very profitable, after all.

Spring and Photography.—Spring and its effects are now with us, and we remind our readers, as we have done in some previous years, that there are many subjects that may be successfully photographed now which cannot be done at any other time with anything like satisfaction. There are, as most are aware, some subjects that are so buried with trees that they are quite hidden when the foliage is on, and to take them when the trees are devoid of it means a sombre and cheerless picture. But, if the view be taken now, while the leaves are small and the colour is light, excellent pictures, with quite a summer aspect, may be secured, yet showing the principal object as well as if it were photographed when the trees were leafless. If the opportunity be lost now, it will not occur again for a year. There are many woodland scenes, too, that will make excellent pictures now that it would be utterly useless to attempt when the trees have put on their full summer garb.

The Metric System.—The general adoption of this system in this country seems to be as far off as ever, if we may judge from the reply given by Mr. Balfour in the House of Commons one day last week. He said that he did not think that it would be within the range of practical politics to impose by law on the inhabitants of this country so great a change in their ordinary habits as would be involved in giving effect to the recommendations of the Committee on the Metric System. This is to be regretted, for, sooner or later, there is no doubt that it will be adopted here. England and America are about the only countries in the world that do not use that system in weights and measures. A Bill on the subject has been introduced into the House of Representatives of the United States, and the result of that, if it passes into law, may have some influence here, as we shall then be left alone in the world with our old system. All Continental photographic formulæ are given on the metric system, and often suffer by being put into English grains and ounces, inches and feet.

Amateur Photographers and the National Gallery.—It will be remembered that a few weeks back we made some comments on the correspondence between Mr. Craigie and the Secretary to the Trustees of the National Gallery, with reference to the refusal to allow amateurs to photograph the pictures. Last week a question on the subject was asked in the House of Commons, and, as might have been expected, the reply given by Mr. Hanbury was practically the same as the reasons we gave as to why they should not have the right, with further remarks added. It was mentioned that students are admitted to photograph the pictures, on the ground that they improve themselves in the knowledge and practice of art by the study of the works of great masters. But no such case can be pleaded for amateur photographers, who will gain nothing in the practice of their art that they could not acquire by photographing any picture not in the national collection; also, that, if they desired to possess the copy of a picture, they could do so at a cheap rate in the market. It is scarcely necessary to add that Mr. Hanbury's reply evoked an emphatic "Hear, hear" from the majority of the Members present in the House.

A Valuable Engraving.—It is sometimes said that the proof of the value of a thing is what it will sell for. On Saturday last, at Sotheby's rooms, an engraving was disposed of at auction for no less a sum than 300*l*. This is about the highest price we remember an engraving fetching "under the hammer." The print in question is a mezzotint by Prince Rupert of Bavaria, entitled, *The Executioner of St. John the Baptist*. It is said that this is one of the oldest mezzotints known. As time passes, so will old engravings, both line and mezzotint, increase in value, for the simple reason that these styles of engraving are fast becoming a lost art. As the old engravers have died off, there have been no new ones trained to take their places. Photogravure has, no doubt, had much to do with this, and we doubt very much, in face of the perfection it has now attained, that, however skilful an engraver of the old style might be, he would now find his work remunerative. Further, plates that used to take even years to engrave are now produced by photogravure in a few weeks—an important consideration, particularly with subjects of passing interest.

Guildhall Water-Colour Exhibition.—The annual loan collection of pictures is now on exhibition in the Art Gallery of the Corporation of London, and a very fine one it is. This year it is confined entirely to water-colour pictures, of which there are about 160, all of the British school. Several of the works have never before been publicly exhibited; notable is one lent by Her Majesty the Queen, Henry Tidey's *The Feast of Roses from Moore's "Lalla Rookh,"* also about twenty little vignettes by Turner, lent by Sir Donald Currie. Amongst the names of the artists represented may be mentioned David Cox, De Wint, Copley Fielding, Birket Foster, Sir John Gilbert, Prout, Holman Hunt, Millais, Poynter, J. W. M. Turner, Clarkson Stanfield, and many others of equal fame.

A GREAT deal has been said at times about the fading of water colours, and that makes an exhibition of this kind additionally interesting to those who have to do with photographs finished in water colours. In some of the oldest works shown at Guildhall—the catalogue gives the date of the majority of the pictures—the colours appear to be as strong and brilliant as the day they were painted; but that cannot, unfortunately, be said of all, even those of comparatively recent date. This rather inclines one to think that modern masters are not so particular as to the pigments they employ as regards stability as were those of the older school. However, very much may be due to the conditions under which the different pictures have been kept as regards exposure to strong light and varying atmospheric conditions.

As this is the only chance that the public will have of seeing many of these works, the opportunity should not be lost. The Exhibition will remain open till July 31, on week days from 10 till 7, and on Sundays from 3 till 7. The admission is free. It may be mentioned that five of these annual loan exhibitions have been held, and they were visited by nearly a million persons, a very good proof that they are appreciated. In addition to the water colours is the collection of works illustrating the sculptor Goldsmith's, a gem-engraver, art, chiefly of the fifteenth and sixteenth centuries, lent by Sir J. C. Robinson. These were in the Exhibition of last year.

PRACTICAL PHOTOGRAPHY WITH RÖNTGEN RAYS.

THE inquiry by "Photophil" (apparently from abroad), in last week's JOURNAL, has confirmed me in an impression I have for some time felt, that some practical instruction in the necessary working details would be interesting and useful to a large number of readers of this JOURNAL, who, being quite ignorant of electrical matters, scarcely know how to set about fitting up the needful apparatus, and who, indeed, do not know what is needful.

This information I hope to be able to supply in the following chapter, with also some idea of the cost. It is about thirty years since I first worked with the apparatus known as a Ruhmkorff coil, and the experience since accumulated I have found useful in enabling me at once to set to work with the Röntgen rays.

It will be well to "begin at the beginning," as I am assuming that my readers know nothing practically of what is required. Every one is, of course, aware that the new rays are connected with electricity and Crookes' tubes; what the latter are, and how the electricity is utilised, will be seen. The process may be briefly epitomised: The electricity is first generated, then altered in character by being passed through a species of transformer termed an intensity coil, then passed into a suitable Crookes' tube. There then emanate from the tube the new rays which have equally interested the general and the scientific public, and about which it will not be needful for me to write.

The Source of Electricity.

It is quite possible to use one of the many forms of "frictional electricity machines" (to use a popular form of description), *i.e.*, that kind of machine in which a glass plate or plates, or a glass cylinder, is turned by a handle when electricity is generated; but, for practical purposes, it will be well to disregard these entirely, and look to current or Voltaic electricity as the source of the required energy. This, where no local electric supply is available, is obtained by the use of one or other of a very large number of forms of "battery," the choice being dependent on various considerations. The battery, the source of electricity, may be likened to the boiler of a steam engine, the coil being represented by the engine, and the forms of battery are as varied as are those of boilers. For coil work it is desirable to have a sufficient supply of electric current of high power, and to have it readily available and constant in character. First and foremost among these sources must be placed the well-known, or, at least, often-quoted, "accumulator;" but these are more costly and involve, when they are exhausted, either the despatch to a storage company for recharging, or this being done by means of a voltaic battery. As it is the purpose of this article to recommend the cheapest and easiest mode possible consistent with good work, I will leave this form aside, after saying that, where available, it is the best form for many reasons.

The Leclanché battery, that may be in the possession of some readers, is by no means a desirable form, as it quickly "polarises," *i.e.*, ceases to work till "rested," and a large number is required to obtain the requisite amount and strength of current. It will not be desirable to enumerate all possible forms of batteries, but a few useful forms will be referred to. They are the Grove, Bunsen, and bichromate batteries, in order of their excellence. The Grove "cells" (*i.e.*, batteries or electricity-producers) are the dearest and best; the Bunsen's are almost, but not quite, as good, and the bichromate batteries are exceedingly useful, handy, and free from chemical vapours. For small coils, nothing could be more handy for an hour or two's work; but, for larger coils, they become expensive if the necessary arrangements for disconnecting, &c., when not in use, be applied. The "two-fluid" bichromates are more useful than the "single-fluid," but, being more complicated, they are less removed from the Grove and Bunsen patterns. If, however, little work is required of them, half an hour or so, occasionally, a supply of the bottle form is serviceable if they are kept clean, and free from the crystals that are apt to accumulate upon the working parts. If it be desired to work for a few hours together, and to get the best form of current possible constant for several hours together, my strong advice is, when accumulators are not available, to select a Grove or Bunsen, preferably the former, which is considerably dearer than the Bunsen, but more durable if properly worked, and giving a stronger supply of the electric current. It consists of an outer cell of glazed earthenware, in which fits a second, smaller, cell of porous earthenware. A piece of zinc, bent letter U shape, is placed in the larger cell, with the other cell inside it. Within the latter hangs a piece of platinum sheet. Proper fittings are supplied for attaching wires to lead away the current generated in these cells. They are put in action by filling the outer cell with diluted sulphuric acid (about 1:12 is a good proportion), and the inner cell with strong commercial nitric acid. This battery should either be placed in the open air or in a fireplace with a good draught up the chimney, as, after it has been working some little time, it gives off objectionable fumes of nitrous acid, offensive to the senses and injurious to any metal fittings which they may come into contact with. Lenses and cameras would soon be injured if the fumes were allowed to escape in a studio, for instance. It is an important point, to avoid wasting the zinc, and to prevent the current being depreciated, to keep the zincs well amalgamated with mercury. Many plans are recommended, but the simplest I think will be the one I adopt. Some bichloride of mercury is placed in a cup, and a mixture of hydrochloric acid and water (one to three) poured upon it, and the mercury salt, say one to ten of solution. This mixture is well rubbed over the zinc surfaces, especially at the inside of the U, with a piece of stick on which has been tied a piece of rag or cotton-wool. The zinc will then be covered with a film of mercury, the advantage of which lies in the fact that, when the battery is not working, there will be little if any wasting of the zinc by the acid acting upon it. The battery is working when the wire leading from the zinc is connected (either through the coil or otherwise) with that from the platinum. When several cells are employed, the zinc should be joined to the platinum and that to the next zinc, and so on, the two fluids of each pair forming a connecting link for carrying the current, This method is called joining the cells in "series," and for working a coil is better than joining all the zincs to one leading wire and all the platinums to another ("joining in parallel").

In order to understand electrical references it may be observed that the positive current is supposed to go out of the battery by the platinum and to enter it again through the zinc, the former being termed the positive pole or anode; the latter, the negative pole or cathode.

Before leaving the subject of batteries, I should impress upon the reader the desirability of most carefully cleaning and washing all the parts when putting it away. The acids should be emptied out, (remembering that nitric acid (aqua fortis) is a most corrosive fluid) and freely diluted with water when running them into the sink. When pouring this latter, or, indeed, any corrosive fluid from one vessel to another, very great care should be taken that no minute drops are allowed to splash into the face, a very little will suffice to blind the eye if spirted in it. All the brasswork should be well washed and dried, as the screw fittings are apt to corrode. Messrs. Griffin have recently supplied me with a set of groved cells in which the ordinary binding screw for binding the platinum to zinc is replaced by a brass clip worked with a helical spring instead of screw, which is a great improvement upon the usual pattern.

G. Watmough Webster, F.C.S., F.R.P.S.

(To be continued.)

DIGRESSIONS.

V.—The Convention.

It is the inalienable right of every man to have a holiday at least once a year if he can get it, and, if he is wise, he will struggle for it. Then let him beware what he does with it, it is too precious to be wasted.

Some say the best way to take a holiday is to get right away out of sight and sound of your ordinary occupation. This is nonsense. I know it from practical experience; I have tried it once in my life and—"never again for me." This was only two years ago, when I went on a cruise in lovely waters, and, with a cruelty that made me feel bad, left my camera behind. The agony of some moments of that voyage was intense. Lovely subjects would persist in arising and deriding the man who left his camera at home. It felt wicked to feel wild that everything was so beautiful. There was one time I remember that was so bewilderingly enchanting, that I could not stand it, and sneaked down below until it had passed.

What is man without the means by which he lives, especially if those means have been chosen as a delight as well as a living? Ask a landscape painter to come into the country and forget his art. The proverbial London waiter enjoys his half-holiday much better if

he employs it in helping a friend, or taking his place, and, at the other end of the scale, I have heard of a couple of millionaire merchants stopping in the middle of a turnip field when partridge-shooting, to discuss the price of produce. Even a golfer, when he goes for a holiday, takes his clubs with him, and, as the busines in life of every young man when he is off his cycle seems to be golf, he certainly does not leave shop at home.

Having exhaustively proved that it is not wise to leave shop at home, the next thing is to find where you can get it best. Fortunately this is not difficult for a photographer to decide, a matter which is already cut and dried for him. It is now becoming one of the best-known facts in the history of photography that the annual meeting of the Convention, wherever it is held, is the happiest place to enjoy talking shop in the world; it is a fairy-land of make-believe, and is not only harmless, but salutary. We Conventionists do some things in the most serious and solemn manner, as though we were *not* out for a holiday. We have an exhibition, so that we can delightfully abuse each other's works, just as if we were in Piccadilly or Pall Mall; we read solemn papers and feel good; we listen and make-believe we are scientific; we dine—this is real—of course, we go to a photographer in our thousands to have our portraits taken, like all good people; and, of course, we have our lantern shows. I am not sure we shall be safe from Röntgen rays, although I don't see how, on the small excuse of our having lent the electricians a prepared plate, they can claim sufficient kindred with us to warrant them in disturbing our enjoyment. There are other matters more mysterious. After all is over for the day and everybody has retired, I have heard it whispered that there are heard "sounds of revelry by night," supposed by those who study the occult to be the echoes of past Conventions which are loth to lose touch with the present. On the next occasion I hear that I shall be a past master, and allowed to investigate these out-of-focus noises, that I hope give delight but hurt not; unfortunately, however, I also hear that the initiated become for ever dumb, and unable to communicate what they know.

But little of this is really real, or feels so. It is just something on which to hang some good solid enjoyment. It is becoming a truism that no public bodies on this earth are able to manage excursions so well as the Photographic Convention of the United Kingdom. Wet or dry, sunshine or shower, or all mixed, nothing seems to interfere. At Shrewsbury last year the county was at our service. The M.P.'s, mayors, town councillors, town clerks, and clerks of the peace of all the towns, turned out to do us honour and promote our enjoyment. Perhaps one of the prettiest and most delicate attentions was the inauguration of a splendid new flag made for the occasion on one of the grandest castles. When, however, that flag was lowered to suit a picture which was thought of more importance than a sentiment, a gloom was cast over the town. At one town, we did not find the mayor in his municipal array ready to meet us, it was raining, not that I would accuse a proud Salopian of minding rain; somebody had blundered. We sent for his Worship, and all available members of the council were hastily assembled. We lectured them on their duties, and they opened their Town Hall to us, brought out all their treasures, and behaved very well the rest of the day.

Towns welcomed us in our hundreds; M.P.'s luncheoned us, manufacturers turned out their warehouses, decorated them and feasted us; private families tea'd us on their lawns, but we were so true to our art that we always returned to—"papers!"

How comes this? It is not always easy to get two or three to gather together to listen to a paper. The reply is simple. Because our papers do not frighten us; *we haven't got a blackboard!* Nobody wants to explain too much; we have no bores. There is always a fear that in every assembly of men there may be one who won't leave off talking; this kind is rare, but exists. I hope I shall never come across one.

We must not forget we are holiday photographers, and would be even as little children for the time, and treated as such. Give us as much information as may be good for us; let it be digestible, we don't want nightmares. If any member seems inclined to go too seriously into things, to ask "why" too often; to suggest "another way" when his road is straight before him; it would perhaps be well to feel his pulse, or look at his tongue. At the Convention last year there were no invalids of the kind, all were in perfect health, everybody's pulse did "temperately keep time." I certainly saw one model of a shutter come out of a pocket, but it was quietly hushed up, there was no scandal.

I am an official this year, so I must be careful what I write; but, I may, perhaps, be allowed to say that I don't think anything very definite ever comes out of conferences. Yet, it is good to talk things over. There is often more effective work done by three men in a corner than by a solemn meeting, and the Convention affords every facility for all kinds of conferences, from a conspiracy of two to a gathering of a couple of hundreds. There are plenty of good subjects. Here is one, for example: Do any of us know what photography really is? We often hear of it, and some remarkable definitions have been given. The very latest is by one I know to be so admirably conscientious that I am sure it is his honest opinion, and, when high authorities go wrong, it is time means were taken to put them right.

In an article in a contemporary, no less an authority than the Hon. Secretary of the Royal Photographic Society gives his notion of what photography should be. Here it is: "Our idea of progress as photographers is to perfect our existing processes, so far as they may be of value, to become, individually, more skilled in them, and to find new principles and new appliances of old principles, so that new processes may be developed." Then he throws down the glove, and says, "Probably no one will dispute this." Won't they? I dispute it altogether; if I were a vestryman I should say *in toto*.

This is where the mischief lies in experimental chemists mistaking themselves for photographers; an honest mistake, I admit, which has been led up to for many years, still a mistake which is the father of mischief. A still higher authority than the one I have quoted, the present (I think) President of the same society, once defined photography as "painting by light." It may be presumptuous for me to say I entirely agree with so high an authority, but I do. I agree also that it is the business of a photographer, as it is that of every worker in every art, to become more skilled in it, although there is danger in painting the lily and gilding refined gold, but I cannot see what perfecting processes has to do with using them.

A workman may perfect a paint he could not use; it is using processes that is photography; and it is not the business of the "photographer"—the user—to worry around after those elusive "new principles," or multiplying new principles, or resuscitating old ones that have been decently buried. But there is something worse that all this leads to, which seems to be the delight of those who erroneously call themselves photographers, but never photograph; I mean that Ghoul-like proceeding which nearly always happens on those rare occasions when anything useful is brought forward. Somebody whose chief aim in life seems to be to recollect dead processes remembers that the new child had reputed grandparents, and hunts for their forgotten remains; finds and unearths them, and exaltingly shouts, "Look here! this is the real old antique process, the young 'un's an impostor!" I don't accuse Mr. Chapman Jones, for whom I have much respect, and if he will come to the Convention, where all would be delighted to see him, I would argue the matter with him for half an excursion.

In the *Year-Book* five years ago, I suggested that professional photographers should take advantage of the Convention to meet together, and, by way of promoting trade, see what they could do towards *ruling the fashions*, and teaching the easily led public what it should buy. I am delighted to find that it is the intention of the National Association of Professional Photographers to throw in their lot with the Convention this year, or, at all events, take their annual holiday at the same time and place. This ought to afford an opportunity which may not—I mean which I hope will—often happen again, for a large number of photographers to hold a sort of conference within a conference, and doing that which in them lies to promote the welfare of the profession generally. I am quite aware that many deem any attempt at combination quite hopeless; much in the past has taken place to help them to form that opinion, but let us try if we cannot "alter all that." We *are* altering it. Look at the Copyright Union. It is so vast a body that it would not do to invite the unanimous members to Leeds during the Convention,

there may not be room in the town, but I hope we may see some of the leading members.

Of course it does not come within the province of the Convention to take part in any conferences on the business of the profession (it being a body of *photographers only*, without distinction of kind; there are no divisions, nor any labels); but an opportunity of meeting often affords the only impetus needed.

I have individually a strong conviction that the old photography, as seen in show-cases and shop windows, is still on the wane, and that something very different, and, needless to say much better, must follow; also that the coming evolution will be a case of the survival of the fittest. To help photographers to think over this matter I intend to endeavour to collect together a little exhibition of modern photography, to show those who have not seen what is now doing in photography, not only in exhibitions, but in some professional establishments.

The photographic memory is short: does anybody remember as far back as 1879? In that year I went into a photographer's to see his place, and found he had abolished his "nitrate bath." A thing around which, for many years, the whole photographic world revolved, but now unknown to the photographer—although I believe it is still used for "process," and on the beach for taking photograms and low-class sixpenny-worths. The other day I asked at a photographers for some albumenised paper, and was told that he had not possessed any, or any shiny paper for months. Now, the moral is, that before about 1879 portraiture was impossible without a nitrate bath, and now it is unknown, and that albumenised paper is following. I think that here are hints of what is coming.

Now, I don't want to bore photographers into joining us; we want only the jolliest of volunteers compatible with a foundation of earnestness; but I ask any photographer, however imaginative he may be, what better programme for a week's holiday he can suggest than the one the Council has issued, for a five-shilling subscription?

What can the matter be this month? I don't know when to stop, but I must tell you this:—

I know a man who once was not doing well and had plenty of time for a holiday, so he sold his watch and went to a former Convention. In a few days he gained more real practical knowledge than he thought existed in the world. The useless theories that had previously filled him were exorcised out of him. The day before returning home he was found on a seat in the town recreation ground in a brooding melancholy. "What is the matter," asked his friend. "I will go home to-morrow," said he, "and it will have to be suicide or dynamite, I didn't know what photography was before." He went home, a divine fury filled him; he destroyed everything in his windows and reception room; started fresh on new lines, and now, instead of not knowing where the next dinner was to come from, he is complaining about how little interest he can get for his investments. Before his awakening, he never read a photographic journal, but I am sure he will read this, for he is now a reformed character, and up to date.

But why tell you anything that the thoughtless may say is romance, when the thing itself is good enough? I expect to see everybody and his wife and all who are worth seeing, at the Convention at Leeds in July, and give this very previous reminder that they may have time to prepare. H. P. ROBINSON.

BY THE WAY.

THE lengthy paper by Dr. Baekeland on the subject of the possible permanence of silver prints does not, I am afraid, add much to our knowledge of the conditions under which we should work in order to secure that consummation, though one or two points are raised which appear fairly open to question. For instance, it is pointed out that developed images are, as a rule, more permanent than those produced by direct printing or "printing out," and, as the particles of silver forming the first-mentioned are coarser than in the latter case, it is suggested that the state of division has a direct influence on permanence. Now, although in the case of silver or any other metal in an extremely fine state of division and unprotected by any other medium or substance from outside influences, the more minute particles might be expected to succumb to such influences more rapidly than the larger, when the silver is imbedded in a protective layer of albumen, gelatine, or collodion, the case is different, and provided the vehicle is thoroughly freed from injurious matter and is also itself of a stable nature, it would seem to me that the more finely divided particles are more completly protected than their larger brethren. Of course, if, from insufficient washing, injurious matter remains shut up in the film, the more finely divided image may be expected to suffer complete destruction more rapidly than the coarser, though the commencement of the action would, perhaps, occur as soon with one as the other. But this does not in any way affect the comparative permanence of properly washed prints.

It is interesting to note that the writer is of opinion that equally permanent proofs may be obtained with any of the vehicles now in general use, or, to use his own words, "it matters little whether it is gelatine, albumen, or collodion," provided, I presume, that proper treatment is given in each case. But it is also interesting to find that, other things being equal, and, in spite of the claims to extra permanence put forward in favour of collodio-chloride, according to Dr. Baekeland, its chances are inferior to those of gelatine, owing to the smaller quantity of silver it is possible to combine with the collodion. His reference, however, to the possible decomposition of the collodion film itself and the disengagement of nitrous vapours will not, I fancy, do much to alarm those who have had any acquaintance with collodion negatives, for these, barring the fragility of the glass, appear to be amongst *the* most permanent of photographic products. That pyroxyline itself will—and rapidly too—give off nitrous fumes is an undoubted fact, but that it does so after its conversion to the condition of a dry pellicle I very much doubt. In the liquid state as collodion it may, no doubt, change more or less; but, if the solvents are pure, not much danger need be anticipated, and I doubt if collodio-chloride prints will give much trouble if the only cause of their fading is to be traced to the decomposition of the pyroxyline.

But Dr. Baekeland does not explain how it is that, in spite of the apparently absolutely permanent character of dry gelatine and the equally suspicious reputation of albumen, gelatine chloride prints do not, in private practice at least, enjoy the reputation for permanency that would seem to be due to them as compared with albumen. We have heard a very great deal during the past few years of the vast superiority of gelatine papers over albumen, and now collodion papers are to supplant gelatine; but the fact remains that albumen paper still keeps its place, and probably will continue to do so—indeed, not a few who have taken up gelatine have had to return to albumen. It is certain that, with an equal amount of care bestowed upon each, albumen prints will be at least as permanent as gelatine, and that, with an equal amount of *want* of care, far more so. So far as these two vehicles are concerned, it may be said that though either will give permanent results when properly treated, gelatine suffers far more in proportion, from carelessness, than does albumen.

The evergreen subject of the colour of negatives and its effect on printing has cropped up once more, and been discussed in all seriousness, as if the actual quality of the print depended upon the colour of the negative, either in its lights or shadows, *as such*. That pyro-developed negatives, exhibiting a certain amount of stain, give, as a rule, better prints than the colourless films produced by other developers, seems to be the general opinion; but it is rather a question of better gradation on the part of the pyro than of colour, otherwise a similar result would be obtained by staining a colourless negative or printing it through a tinted glass. Undoubtedly, there are circumstances under which the latter treatment becomes most useful, but it would be obviously foolish, because yellow glass and slow printing suited one particular negative, to submit to the inconvenience in all cases. That pyro still remains the favourite developer seems to be indisputable, but that it owes the quality of its results to its staining powers I for one refuse to believe; and I think, if an equal amount of study were given to some of the newer agents, they would be found to give equally good gradation with far quicker printing qualities. A quick-printing negative does not necessarily, mean a thin one, and, *per contra*, a slow printer does necessarily yield a print that is rich in silver deposit. That quality depends

entirely on the gradation, and not at all on the mere density of the negative.

Speaking of the colour of the negative naturally suggests thoughts of sulphite of soda, and this again reminds me of a recent editorial allusion to an "amusing reply" to a photographic query in one of the evening papers, in which sulphate of soda was given as an ingredient of this developer instead of sulphite. Without for one moment supposing that the use of that chemical, either in the "reply" or in the "handbook" referred to in last week's JOURNAL, was anything but a printer's error, I would point out that the employment of that salt is not, after all, so absurd as many may perhaps imagine. That it possesses the same properties as the sulphite as a preservative of pyro is, of course, not a fact, but it has its own peculiar characteristics, which may render it a valuable addition to the developer under certain conditions. The late Herbert B. Berkeley first pointed out the fact that the sulphate of soda, in common with many other apparently neutral salts, acts as a very powerful restrainer, and is capable, in a measure, of replacing bromide in the developer. A notable instance of this is to be found in the ferrous-oxalate developer made by mixing solutions of oxalate of potash and sulphate of iron, in which sulphate of potash is formed by double decomposition. This mixture can be used, and will develop with perfect clearness, without further addition of bromide or acid, where the solution made by dissolving oxalate of iron in oxalate of potash would veil the image badly. Some two or three years back a writer in a German periodical recommended the substitution of the sulphate for the sulphite, and where the preservative and stain-preventing actions of the latter are not required it will be quite as useful; in fact, perhaps it will prove to be identical with much of the so-called sulphite that gets into use.

When a member of a photographic society gets up to read a paper, it is usually supposed that he has something to say, and means to say it seriously, but I am at a loss to decide what proportion of the lecture delivered before the Moseley and District Society, reported last week, should be considered as serious, and how much as facetious. That "hydrogen is no bachelor," and that sub-bromide of silver is "a weak maid," are probably new chemical facts, stated in what is intended to be a "funny" way. But when the "no-bachelor" hydrogen joins "the ($2NH_3$) ammonia, and makes another composition of ammonia ($2NH_4$), which subsequently reduces the weak maid, I fancy the lecturer must have lost himself amongst his similes. What $2NH_4$ means, and how it acts upon the sub-bromide of silver, requires some further explanation. If the lecturer had made the uxorious hydrogen go directly to the weak maid without the intervention of any matrimonial agency in the shape of $2NH_4$, he would perhaps have been nearer the mark; but, as it is, I wonder why, to borrow the title of his discourse, he undertook to explain developments.

I should not again have referred to the single-transfer carbon dispute had it not been for M. Demachy's and Mr. Maskell's letters, and only do so now to say that the question is not worth further argument on the lines adopted. I simply said, and say, that true and proper gradation can only be got by transfer, *i.e.*, by development from the back. If the gentlemen named hold that their pictures satisfy the conditions, well and good—they are their own judges, and should be satisfied—My acceptance of Mr. Maskell's challenge would be useless on my part or any one else's, as I don't think Mr. Maskell would be satisfied with anybody else's decision but his own, and that clearly would not satisfy anybody else who thought differently.

DOGBERRY.

PHOTOGRAPHIC WORKERS AT WORK.

IV.—How Messrs. Beck Make a "Frena."

The outside appearance of a Frena and its ingenious method of film changing must be well known to our readers, so that a description of a visit to the works, in which we had an opportunity of seeing the entire operation, and of having the various operations explained to us by Messrs. Beck themselves, is sure to command a certain amount of interest.

The "Frena" cameras and their offshoot, the Frena film-changing box, are the positive outcome of many years' design and experiment, the negative results of which are to be seen in a host of models of discarded appliances and a cabinet full of elaborate drawings and workshop sketches, which were the first thing shown to us. Mr. Conrad Beck told us that, in the course of three years' experimental work, every film-changing principle then known, with one exception, was tried before the Frena was finally adopted and made. In this collection too are to be seen the earlier drawings of the Frena itself, and here a word or two may be said as to the system employed in the factory.

When the general idea of an instrument has been decided upon, its design is got out in drawings, in which every dimension is carefully indicated, and from these drawings a model is made. The model is almost certain to suggest various alterations and additions which are carried out upon it, and then, when the form is finally settled, fresh drawings are made from which the workshop sketches and tracings are obtained. All drawings used in the factory have the dimensions marked upon them, not in inches and fractions as is usually the custom, but in whole numbers representing hundredths of an inch. From the designs obtained in this manner gauges and templates for every dimension of every part are made, the complete set of templates for any one instrument being kept together in one box, a list of them entered in a register and consecutive numbers given to each template, which numbers are marked upon the drawing.

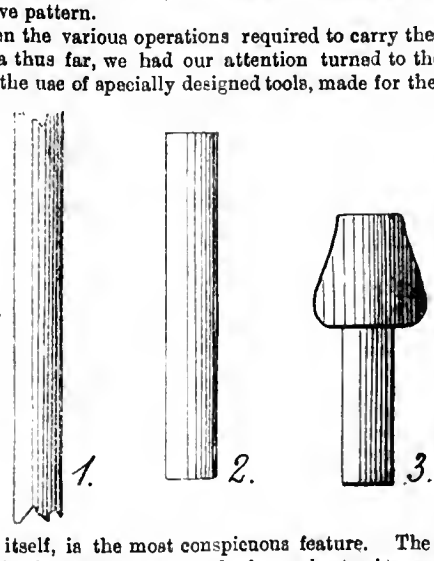
At Messrs. Beck's works everything is regular and systematic, machinery and special tools being used wherever possible. By doing this, by making every part rigidly to gauge, and by making large quantities of each part at a time, the final putting together is largely facilitated, and all the cameras are entirely interchangeable. Over and above all this is the reduction in the price of the finished article which is thus ensured; in fact, Mr. Beck informed us that it would be impossible to make the Frena commercially if this were not done without putting in a cheap lens.

Leaving the drawing office, we first visited the wood-working department. Here the timber is stored for some time before being cut up, after which storage is finished the wood is roughly planed and sawn into the sizes required, the date of purchase and of cutting being stamped on each, and the cut pieces, separated to expose them as much as possible to the air, are kept, where possible, for nine months, to thoroughly dry. This over, they are taken in hand once more, and planed and cut until they are all ready to go together to form the camera case. Space precludes us from describing the various forms of wood-working machinery employed, but one formidable machine was pointed out in which a row of knives, whirling round at a rate of two miles a minute, was cutting the wood quickly and leaving it as smooth and even as could be desired, and sending out a perfect fountain of chips in so doing.

Lightness and strength are the requisites for the timber used in hand-camera making, and to this end American whitewood is exclusively employed in the Frena. To avoid difficulties in the tropics, moreover, no glue is used in putting together.

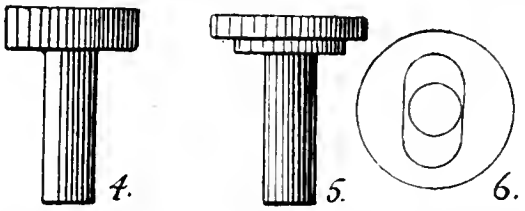
When the whole of the various pieces are completed (and we may mention here that a thousand Frenas are put in hand at a time) the woodwork is fitted together and the leather covering put on, this being done before the metal work is attached to the instrument. The leather employed is imported by the firm; it consists of ox hide, and has a pleasing and distinctive pattern.

Having seen the various operations required to carry the manufacture of the camera thus far, we had our attention turned to the metal work. Here, again, the use of specially designed tools, made for the most part in



the factory itself, is the most conspicuous feature. The whole of the metal parts in the camera are made from sheet, wire, and tube metal, turned and stamped to the form required, not a single casting being used We were shown a glass case in which were displayed the 303 separate

pieces of which each No. 2 Frena is composed, exclusive of nails. Of these 303 pieces, 176 are pins of more or less special design, each form of which is made from brass wire by means of a special tool. The evolution of one of these may be taken as typical of many others, and is seen in the accompanying sketch. The wire which is first shown is submitted to four operations, the first a cutting one, the remainder stamp it until it reaches



its final shape in No. 5, No. 6 being a view of the under side of the head to show the shoulder, the shape of which could not be indicated in No. 5.

The mechanism of the Frena is too well known to call for any detailed description here. Its chief feature is that it carries forty flat films in a pack, which are changed automatically by simply turning a handle, and has, with a reliable adjustable shutter, a really good lens. The box which carries the films, in the first cameras issued, was made of a length of square brass tube, but has now been both simplified, and at the same time is made more economically, by stamping out of sheet metal.

The various metal parts, like the woodwork, are made in batches sufficient for a thousand cameras at a time, and are stored all ready to be put together. The boxes in which they are kept in their respective pigeonholes each have a big E printed on one end. So long as the box is in use, this end is turned next the wall, so that the E is not visible; but, when empty, the box is turned with its other end inwards, so that the E is seen, and the state of the stock of any particular fitting can thus be ascertained at a glance. The actual putting together, in consequence of each part being accurately made to gauge, is a very simple affair, the adjustment of the fixed focus lens being the most interesting portion. This adjustment is made by sliding the film-holder in the framework that carries it in or out until the correct position is ascertained, when it is fixed once for all by three screws on each side. To do this, the camera is clamped securely on a wooden stand, the film-carrier and its bearings being attached to a framework carrying an eyepiece magnifying forty times; this framework, and consequently the film-carrier, can be moved farther into or out of the camera case carrying the lens by a lever, a large movement of which shifts the framework but slightly, and so a very nice adjustment is possible. With this magnifier, using as an image on illuminated grating at a certain distance down the shop, the exact relative position for the lens and sensitive surface is ascertained, and before the camera is released from the apparatus this position is ensured once for all by the screwing up of the three screws on each side already referred to.

The camera, having been put together, has to be tested, which is done in a particularly thorough manner. No camera is allowed to leave the works until, in addition to a photograph being taken with it, every part has been distinctly examined and certified to be in the right condition. To ensure this, the tester has to fill in a form giving the number of the camera, date of testing, and signature of the person carrying it out, which form has to be marked for each particular examined. As an example of the exhaustiveness of this test, we cannot do better than reproduce that part of the test sheet which refers to the film-holder only, the other fittings, the shutter and the camera generally, being dealt with in a similar manner.

Holder.	
The blind tight	
,, ,, properly fastened	
Swing back easy	
Gravity latch acts...	
Holder correct size	
,, square	
,, vertical	
,, pins correct length	
,, fits between sides	
,, burrs removed from inside	
Pressure board and spring flat	
Sliders travel full extent...	
Indicator correct	
Handle parallel with top of case	
,, level sound	
,, easy with forty films	
Forty films passed through	

It is only when the camera has thus been tested in every particular, and a photograph taken with it, that it is ready for the market, and the negative and record of the test is filed.

So far, we have seen the wood and metal work made; one of the most interesting parts of the firm's manufacture has still to be seen, we refer to the lens-grinding shop, which we were next shown, giving a glance by the way at the ten-horse gas engine, which is the motive power of the factory, and a shed in which the operations are carried out which impart that fine dead black to the brasswork which renders it so attractive and at the same time reduces awkward reflections to a minimum. We cannot also do more than allude to that part of the works devoted to the manufacture of other optical instruments, since the interest of this article centres round Frenas.

In the lens-grinding department are to be seen lenses in all stages, from the rough slab of glass as it comes from the glass works to the finished and mounted objectives, which latter range in size from parts of microscopic objectives about the size of a pin's head to telescope lenses several inches in diameter. Our appreciation of the rough-looking slabs of glass is much increased when we hear that their price ranges up to as much as 2*s.* 8*d.* per ounce; much of the glass employed, particularly the more expensive varieties, has to be obtained from the Jena factory. The operations of manufacture consist of a rough grinding to approximately the shape required; in some cases the glass itself is supplied moulded to the form required, and, this first operation avoided, the roughly shaped, however obtained, is then gradually carried finer and finer until the lens is ready for polishing.

It seems of the simplest possible nature, but we are told that it requires years and years of practice before a man acquires that delicacy of touch or knack by means of which the grinding tool curved to the form required is kept moving irregularly over the face of the work, so that the pressure is even over the entire surface and the curve desired is obtained. Machine work here is out of the question, human skill being the only means by which each lens can be satisfactorily made. In this department the Frena lens, which we learn is by far the largest item in their cost, and the Frena "magnifiers" or supplementary lenses, are made and tested, the latter operation being carried out so completely that no less than eleven tests are made of each lens before it leaves the department to be inserted in the camera.

More, a great deal more, could be said about the many interesting operations which are carried on at Messrs. Beck's factory. Exigencies of space have compelled us to pass over the Frena film-carriers, telescopes, microscopes, and many other instruments which are made here. In fact, the two or three hours spent by us, here could easily have been extended to four or five times that length without exhausting the sights which appeal to and interest photographers. We are compelled, however, to omit the description of much even of what we did see in that time, and to strictly limit this article. We can only conclude by recording our obligations to Mr. Conrad Beck, Mr. William Beck, and Mr. Horace Beck, for the trouble to which they put themselves to enable us to lay before our readers some account of how they "make a Frena."

ASTIGMATISM AND A NEW "STIGMATIC" LENS.*

In the first place, the simplest form of a stigmatic lens consists of a glass plate with parallel plane sides. Since, however, such a lens has an infinite focal length, we must modify this lens in such a way as to obtain a positive focus without altering the astigmatic constant. There are three principal methods to proceed by (fig. 4).

(1.) Let us divide the glass plate into two lenses by means of a curved surface and then separate these lenses. In all cases, by so separating the lenses, we shall at once obtain a positive focus, depending on the amount of the separation. This separation, as we have seen, has no effect on the astigmatic constant, and thus our first method consists in the use of strong positive and negative lenses separated by considerable intervals.

(2.) Let us suppose the surfaces of the plate to be, instead of plane, equally curved. In this case also we shall obtain a positive focus depending on the thickness of the plate, with, at the same time, zero astigmatic constant. More generally if we have two meniscus lenses with equal external curvatures, but one thick and the other thin, the astigmatic constants of the two will be the same, but the thicker lens will have the shorter focus, and consequently the thick meniscus has smaller astigmatic constant proportionally to its focal length. Our second method is, therefore, the employment of *thick* meniscus lenses. This method, in reality, closely resembles

* Continued from page 264.

the first; there we have converging and diverging lenses, separated by a considerable interval, and here converging and diverging surfaces separated by an interval.

(3.) If we make up our glass plate of a crown-shaped lens of high refractive index, and a flint-shaped lens of low refractive index, we shall also be able to obtain a positive focus with zero astigmatic constant. On account of the different factors by which, as I have

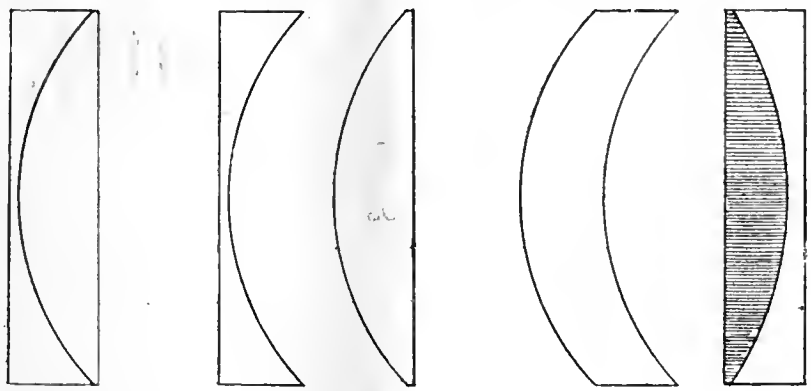


FIG. 4.

said, the thicknesses of lenses of glass of different refractive indices must be multiplied, it will be found that this form of lens must be actually thinner in the centre than at the edge to give zero astigmatic constant, though at the same time it will give a positive focus. On the other hand, with a (thin) lens made up of a crown-shaped lens of *low*, and flint-shaped lens of *high*, refractive index, to get zero astigmatic constant, the thickness in centre will be slightly greater than at the edge, but at the same time the *focus* will be negative.

It will perhaps be of interest to discuss some lenses which exhibit these types of correction. With respect to our first principle, the old triplets of Dallmeyer were an example of its partial employment, and these lenses are still well known for their flatness of field. Lately we have, of course, had a lens in which this principle has been more fully carried out. There is also a very old instance in which this principle was very fully employed, of which I shall give you a detailed description, as I believe it is not very well known. A year or two ago, while looking over some old photographic papers, I came across some old experiments of Professor Piazzi Smyth, then Astronomer-Royal for Scotland. Piazzi Smyth wanted a lens working at *f*-3 with a flat field free from astigmatism. He found, as we all know, that by shortening the tube of his portrait lens he could get rid of the astigmatism, though at the same time introducing a great deal of curvature of field. He then cast about for some means

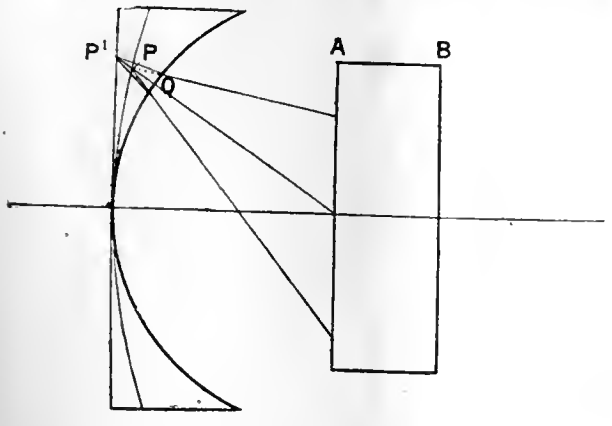

FIG. 5.

of getting rid of this curvature of field without introducing astigmatism. He found that he was able to do this by placing a strong negative lens just in front of his sensitive plate, and, since the reasoning by which he arrived at this construction is interesting, I shall here give it. These experiments were carried out in the old collodion days, and, since Piazzi Smyth was exposing his sensitive plate while actually in the bath, he had to put a glass plate in front of the plate to prevent the liquid from spilling. Finding that this plate had the effect of slightly lengthening the focus of his portrait lens, and the more so the thicker it was, he at once argued that if he used a plate of varying thickness, in fact one that was thicker at the edge than in the centre, he should be able to lengthen out the marginal rays, and so obtain a flat field without astigmatism. You will at once see that this is merely an application of my first principle; we have here a strong negative lens as far removed from the positive lenses as possible, and, further, the proper curvature of the "corrector" lens can be at once determined by the fact that it must be as much thicker at the edge than at the centre as the lenses of the portrait are thicker in the centre than at the edge. I have here a portrait lens with a properly curved field and its corrector lens by which I can at once show the feasibility of this plan.

By drawing a figure showing the path of the rays it is easy to see how this flattening effect takes place (fig. 5). The curvature of the deep side of the corrector lens must be about three times the curvature of the field, consequently the marginal rays meet the surface of the corrector lenses sooner than the central rays, and are thus more lengthened than the central ones; thus, in previous figure, μ being refractive index and r radius of curvature of curved face of corrector lens—

$$\mu\left(\frac{1}{P^1Q} - \frac{1}{r}\right) = \frac{1}{PQ} - \frac{1}{r}$$

or

$$\mu\,\frac{r - P^1Q}{P^1Q} = \frac{r - PQ}{PQ}$$

or nearly, since P^1Q PQ are very small

$$\frac{\mu}{P^1Q} = \frac{1}{PQ}$$

Now curvature of image : curvature of face and lens

$$: : P^1P : P^1Q$$

or as $\mu - 1 : \mu$ or approximately 1 : 3.

The thick aplanats of Steinheil (and the similar lens known as the portable symmetrical of Ross) also the Steinheil antiplanats and the Zeiss and Goerz anastigmats really come under the second type of correction.

Under the third type of correction we have the anastigmat of Hartnack, and the "Concentric" of Ross. As before pointed out, lenses of this type have to be actually thinner at the centre than at the edge. The Zeiss and Goerz anastigmats, properly speaking, do not come under the third head at all, for, though they contain crown lenses of light refractive index, they also contain crown lenses of low refractive index, the two nearly neutralising one another.

Having thus dealt with the question of astigmatism, it now remains to take account of spherical aberrations, or the aberrations which show themselves when we are dealing with pencils of finite size. For the reasons I have already set forth, I shall now consider only rays of pencil which lie in the primary plane, *i.e.*, the plane containing the radiant point and the axis of the system.

In the first place, there are really two conditions for complete aplanatism for an optical system, and not one, as is usually stated, though only one of these appears for large pencils, whose radiant point is on the axis of the system—the form of spherical aberration in primary plane, which only appears for large pencils whose radiant point is not on the axis of the system, giving rise to the effects usually known as "coma."

Referring to our former figure, we see that, in the large pencil from P incident on the system, the refraction of the two halves of the pencil separated by the principal ray is exactly the same, and consequently only one condition for aplanatism arises, whereas in the large pencil from Q the refraction of the two halves of the pencil is dissimilar, and consequently we obtain two terms (which have each to be made zero for aplanatism) in the spherical aberration of such an eccentrical pencil. Further, if all the rays from an extra axial radiant point Q (in primary plane) after refraction pass

through one point, Q_1^1, it is evident that the primary curvature of the system is independent of the position of the small stop, R. The converse of this is also true, *i.e.*, if we investigate the condition that the primary curvature shall be independent of the position of the stop, we obtain two conditions which are in fact the conditions for freedom from (what are usually termed) spherical aberration and coma. But, since there is also the question of distortion to be considered, I prefer to attack this question in a different sort of way. On account of spherical aberration and curvature of field, the distortion of the general optical system depends in general on the position of the small stop, thus (fig. 6).

As in our former figure, let P^1Q^1 be the conjugate plane of PQ. Let QR be a ray from a point Q on the object, passing through a small stop at R, suppose this ray after refraction meets the conjugate plane at Q^1; let N_1 N_2 be the first and second "nodal" points of the system; draw N_2Q^{11} parallel to N_1Q meeting the conjugate plane in Q^{11}. Now, distortion consists in change of scale in different parts of the image. According to the Gauss theory the scale of image: object for parts of image *near* to axis is P^1N_2: N_1P or P^1Q^{11}: PQ. Now, the point on the image corresponding to Q is plainly Q^1. Hence, we may take Q^1Q^{11} as a measure of the distortion with a small stop at R. An expression in perfectly general terms can be obtained for this quantity, Q^1Q^{11}, and we shall find that, if this quantity is to vanish for all positions to the stop R, that we must satisfy four conditions amongst the constants of the optical system. Two of these conditions are the same as those already mentioned for freedom from spherical aberration and coma, a third is necessary that the curvature in primary plane should vanish, if these three conditions are satisfied, the distortion is constant for all positions of the stop, R, and a further condition must therefore be satisfied if this constant value of the distortion is to be zero. There is also the condition that the astigmatic constant shall vanish, and three conditions for complete achromatism, in all eight conditions to be satisfied by an optical system free from all spherical and chromatic aberrations, curvature of field, astigmatism and distortion. The conditions

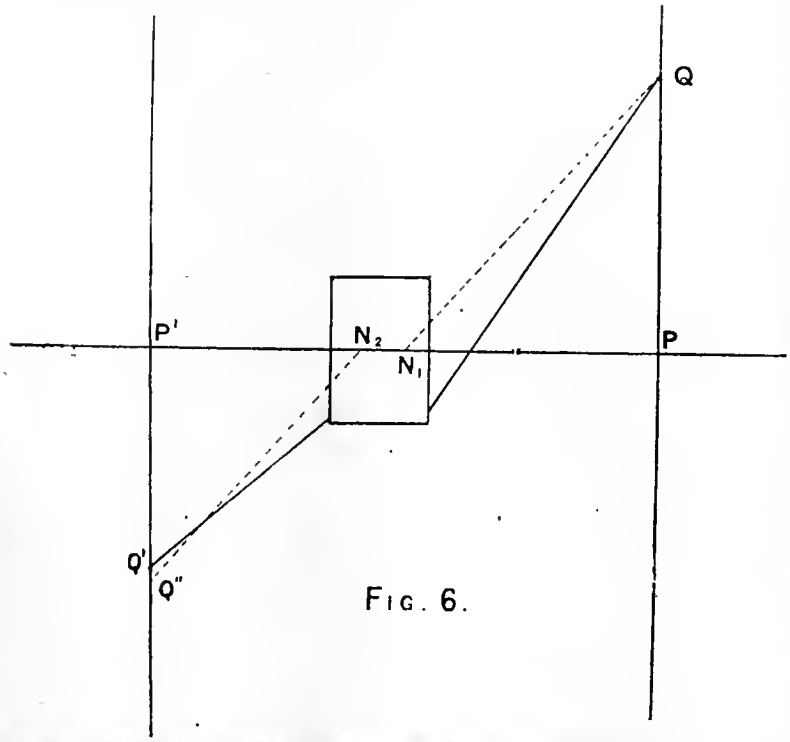

FIG. 6.

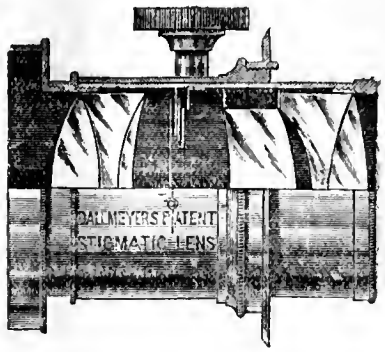
for achromatism are, as a rule, easily satisfied on account of the variety of glass with same refractive indices and different dispersions now at the disposal of opticians. My method, then, of constructing such optical systems is to write down the above conditions in general terms, and treat them as equations for determining the curves, and thicknesses, and separations of the lenses of the system.

The first lens that I have worked out by these principles is here figured. It resembles in general form the type of portrait lens introduced by the late J. H. Dallmeyer in 1866. The chief points of difference are:—

(1) That the back combination is a weak negative lens instead of a positive lens.

(2) The refractive indices of the cemented lenses forming the front combination are all high, and nearly equal. The back com-



bination is formed of crown-shaped lenses of high refractive index, and flint-shaped lenses of low refractive index.

(3) The front lens is an unusually deep meniscus.

H. L. ALDIS, B.A.

THE TONING OF BROMIDE PRINTS.

A MINOR department of practice, which may be safely left for attention when days are dull and clients few, is the resuscitation and rejuvenation of faulty bromide proofs.

In exposing and developing a dozen or so of bromides, it is very rarely indeed that a percentage of more than eight out of twelve turn out really good and fit without further treatment. If, however, we thoroughly fix, wash, and dry the remainder—treat them, in fact, as if they were just as perfect as the others—we shall often find it worth our while at some leisure time to devote a few minutes to them, for it often happens that out of this lot of faulty wasters we can get one or more prints which really may surpass the first and selected prints in tone and brilliance. In other words, the ugly duckling may develop into a swan of wonderful plumage.

It is never too late to mend a poorish bromide provided it has been properly *fixed* and *washed*.

I lately found, in a most unexpected place, a roll of bromide prints, 15 × 12, which, I should think, were at least seven years old—wasters presumably, and yet had evidently been stored away carefully, in the hope of a time coming when something could be done with them. They were a find in their way, being the sole remaining prints of a medal negative which had some time ago gone over to the majority.

The prints were badly stained (iridescent stains), inclined to be mouldy, had some symptoms of light fog, but were fully developed—had been developed with ferrous oxalate—and were of a greenish tinge far from pleasing.

A glance through the JOURNAL in search of information bearing upon the subject was, of course, useful, inasmuch as a variety of formulæ was very quickly discovered.

It is clear that nothing can be done of any value if the fixing of the print has been imperfect, or if the washing has not resulted in a complete elimination of salts. The first thing to be done was, in the absence of any confidence in what had gone before, to once more *fix* these prints and wash them. This was done, and they were ready, after drying, for further treatment.

To tone or intensify—for that is usually what it amounts to—is never to be done in the absence of a really effective clearing bath. The surface of a bromide print—or any other film for that matter—is never in a good condition for this operation, unless it has a mild, but effective, sort of "shampoo process," which leaves it in the best possible condition to receive the action of the toning salts.

From the appearance of the stains and fog, Howard Farmer's reducer was instantly judged to be the best "clearing" agent for this purpose. For my own part, I very rarely intensify without first submitting the film to the action of this excellent bath, and in the present case the prints were, as may be expected, greatly improved. The iridescent stains cleared off, the light fog dispersed; but in one case, that of a print not so fully developed out as the others, it was cleared at the expense of the high lights, which then had rather a chalky appearance. A second washing followed, using

gentle friction with wet wool at intervals, to completely clean the surface.

Three toning baths were used:—Firstly, the alum and hypo bath of the Eastman Company. Their formula is as follows: Sodium hyposulphite, ten ounces; dissolve in three and a half pints of boiling water, then add gradually one ounce of powdered alum. This bath was made and kept some days before use. It was then warmed to 100°, and two prints immersed therein. They took quite thirty-five minutes to tone, and were distinctly the better for the treatment. There was rather more reduction of density with this bath than I expected; but, as the prints were quite over-dense to start with, they were all right in the end. The prints were placed after toning in a simple solution of alum (three-quarters of an ounce to the pint of water), then washed and dried.

The second lot were toned with uranium, *e.g.*:—

Mix freshly—

Red prussiate of potassium	4 grains.
Water	4 ounces.
Glacial acetic acid	150 minims.
Water	4 ounces.
Uranium nitrate	4 grains.

The prints were not *immersed* in the above, but, having been wetted thoroughly and attached, face up, to a piece of plate glass, the solution was applied by means of cotton-wool, the whole of the face being well and carefully attended to. Toning proceeded so slowly with this bath that I added a few drops of ordinary "mercurial intensifier" (the usual five per cent. solution), and got, in a few minutes, a very nice *dark oak* tone, which admirably suited the subject. By *surface* toning, the risk of staining, degradation of the whites, &c., is reduced to a minimum, and washing, though thorough, need not be prolonged.

The best results were, I think, got by means of the method suggested, I believe, by Mr. Chapman Jones, viz., bleaching with mercury and redeveloping. For this purpose, a fresh bath of mercury bichloride was made, one part in forty of water. Bleaching in this diluted bath proceeds slowly, steadily, and *evenly*. *Thorough* washing follows. This is once more *essential*, otherwise development will be local and patchy. Redevelopment is effected with eikonogen, amidol, hydroquinone, or ferrous oxalate, but the solution must be moderately weak, the chloride image being very easily reduced. On the whole, the results were better with this method, but merely on *accidental* grounds. The few small, mouldy patches showed up less with this operation than with either of the others, and these, after mounting, were more easily obliterated with the pencil. The operations of redevelopment, &c., may be carried out in daylight. The prints are to be washed and dried.

It is quite clear to me, as the result of these few trials, that, with a little more care, a much higher percentage of successes in bromide printing would result. Let the prints be made the best of at the time, then thoroughly fix, wash, and dry the lot; but do not reject, without a trial and due consideration, those which may be below the mark, for something may be made of them. J. PIKE.

PHOTOGRAPHY WITH THE BICHROMATE SALTS.

THE third of the series of lectures upon this subject, organized in connexion with the Affiliation of Photographic Societies, was delivered on April 24, by Mr. W. E. Debenham, the subject on this occasion being *Collotype*. There was a larger attendance than at the previous lectures, about fifty persons being present. Having sketched the principles upon which the process depends, Mr. Debenham gave a demonstration of the same, entering very fully into the *minutiæ* of Albert's method, from the cleaning and grinding of the glass plate to the pulling of proofs in the press. The formula recommended for the first coating, to secure the adhesion of the sensitive film to the printing surface, was as follows:—

Water-glass (silicate of soda)	1 ounce by measure.
Beer	15 ounces ,,
Caustic soda	30 grains.

The caustic soda was not always used, but was desirable if the beer was in the least degree sour; ordinary "four-ale" was frequently used, but Pilsener beer was to be depended upon for the purpose. The solution required repeated filtration, and every precaution must be taken to prevent the formation of bubbles or froth. The second, or sensitive, coating was made by swelling an ounce of middle-hard gelatine in water, straining off the water, adding 2 ounces of a ten per cent. solution of the bichromates of ammonia and potash, 1 drachm of ammonia, and a little chrome alum (the latter fulfilling the double purpose of hardening the gelatine and forming a grain), and making up the whole to 12 ounces. The plate having been coated was placed in the drying oven to dry, the proper temperature being 120° to 130°. The lecturer then referred to the preparation of the negative for printing, the exposure and subsequent washing out of the soluble salts, and proceeded to explain the details of the printing in the press. There were, he said, two or three methods of printing, one being simply to damp the plate, as a lithographic stone is damped, dabbing the surface until no shining spots of water remained, and then to begin to ink. The usual method, however, was to pour on the film a so-called etching solution, which was allowed to act for a few minutes, and which consisted of glycerine, 5 ounces; water, 3 ounces; and salt, 1 drachm. White spots on the collotype plate might be remedied by touching them with Indian ink ground up in a solution of tannin. Mr. Debenham concluded by saying that he believed this to be the best method of photo-mechanical printing; block printing was now done exceedingly well, and could be produced much cheaper than collotype; but for the true rendering of nature, without loss of detail or gradation, he thought there was no process to equal the latter.

Friday, May 1, *Photography and Photo-zincography*, by Mr W. T. Wilkinson. Syllabus.—Requirements of a photo-litho transfer; the paper; sensitising the paper; the negative and exposure to light; inking up the print; development; use of various colloids; direct method on zinc; half-tone photo-litho; collotype grain; screen grain; photo-zincography in line; the negative; preparing the metal; printing, development, and preparing for etching; half tone; the negative, printing on zinc in albumen and fish glue and on copper.

(*To be continued.*)

CAMERA CLUB CONFERENCE.

THE eighth annual Conference of the Camera Club was opened at the Club House, Charing Cross-road, on Monday evening, the 27th inst., by Captain W. de W. Abney, who, at the annual general meeting held in the previous week, had been re-elected President of the Club. The exhibition of members' work, which is held contemporaneously with the Conference, includes a number of excellent examples, but on Monday evening the hanging appeared to be unfinished, and a catalogue was not easily discoverable. Captain Abney, in formally opening the Conference, thought there was reason for congratulation in the fact that the meetings were to be held in the Club's own premises, rather than in the less convenient rooms of the Society of Arts, as had been the case on previous occasions, except the Conference of last year, and that it had been arranged to hold no afternoon meetings.

Lord Rayleigh gave an account of his experiments in

THE REPRODUCTION OF DIFFRACTION GRATINGS

by photographic means. At first sight, he said, it would appear to be a comparatively simple matter to make a grating upon a large scale and reduce by photography, but, if one went into figures, this method was not so promising as it looked, for a grating of 10,000 lines to the inch magnified 1000 times, so that there were ten lines to an inch, a convenient size, would require the wall of a cathedral to hold it. There was no simpler or better plan than to copy the original—ruled by a dividing machine—by the process of contact printing, and for this purpose the best support for the sensitive surface was optically worked glass, as very close contact was necessary, although selected pieces of ordinary plate would enable one to obtain good results. The old albumen process was very useful on account of the almost complete absence of structure in the film, and because the hardness of the surface rendered the result comparatively little liable to injury; he had also used with success the dry-collodion processes, particularly the tannin method, and some of the direct printing processes, such as the collodio-chloride, which, worked upon glass, gave excellent results. In the latter case, considerable advantage accrued from treating the finished print with mercury in the manner commonly used for intensification, except that the treatment should stop with the mercury, and not go on to the blackening. The grating after bleaching appeared much less intense than before, but the spectra became very much more intense. More than twenty years ago he obtained very good reproductions by the bichromated gelatine method. The performance of photographic copies was quite equal to that of the originals, except where there was some obvious defect, and, in respect of brightness, it not unfrequently happened that the copies were far the brighter, although, if anybody was anxious to make him a present, he would prefer to have an original. In order to do anything like satisfactory work with diffraction gratings, it was necessary, not only to have a very great number of lines, but to have them spaced with extraordinary precision, and wonderful success had been attained by means of the beautiful dividing machines of Rutherford and Rowland; uniformity of temperature must be carefully maintained, as the slightest expansion or contraction would bring the grating and its resulting spectrum to utter confusion. A grating upon speculum metal, although excellent for use, was not easily reproduced, but he had, to a certain extent, succeeded in copying one. He had recently endeavoured to copy diffraction gratings by the bitumen process, with which it was necessary to give two hours' exposure to sunlight, and to develop with turpentine, but he had not succeeded in finding a means of getting rid of the turpentine without causing disintegration of the film.

Lord Rayleigh passed round for examination several copies of gratings, and in the course of the subsequent discussion some suggestions were made for the removal of the turpentine used for development in the bitumen process. Mr. Pringle suggested spirit of wine, and the Rev. F. C. Lambert proposed oil of lavender, but Lord Rayleigh said he had succeeded best by washing in a strong stream of water.

Mr. Leon Warnerke referred to the possibility of making a mould of a grating in Spence's metal, which would yield an impression of a greasy finger tip.

The Earl of Crawford said an impression of breath upon glass could be made in Spence's metal, but to properly use that material it was necessary to keep it at a particular temperature, which was not easy, and the metal was not now obtainable. The discussion was continued by Messrs. J. W. Gifford, R. Child Bayley, Charters White, and others, and closed by the President.

(To be continued.)

The Inquirer.

*** *In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* JOURNAL *useful and instructive.*

CARBON PRINTING. (To J. C.).—A negative suitable for gelatine and collodion is absolutely unadapted for carbon printing, being much too thin, in consequence, of course, giving a very weak print, or, if over-printed, a flat, heavy one. In fact, collodio-chloride, which J. C. says give him good brilliant prints, is generally recommended as giving good prints from negatives which are much too thin for any other process. Carbon requires a rather particularly plucky negative, as J. C. would know if he had studied his text-book instructions, indeed it will stand a greater amount of contrast than any other process in which I have had experience, albumen coming next on the list, then hot-bath platinotype, then cold-bath platino., then gelatino-chloride, and then, as a last resource, collodio-chloride.—W. BENINGTON.

CHLOROPHYLL. (To W. H. G.).—I have known chlorophyll to be effective when applied as a bath to gelatine emulsion plates and followed by immersion in water, but its action is very uncertain. It can be made always effective by flowing the plate with a strong alcoholic solution, draining and *drying*, then immersing for a minute in distilled water. This method succeeds with all colour-sensitisers not perfectly soluble in water. But I cannot recommend chlorophyll for use with gelatine dry plates even when applied in this way; cyanine is better.—F. E. IVES.

DARK ROOM FOR DEVELOPMENT.—B. G. DAVIS says: "I should be much obliged if either you or your readers could inform me of any place where, by means of a small subscription, I could develop any photographs that I should require. I am aware that a great many makers of cameras have dark rooms for the use of their customers, but they all close at 6.30, which is too early for me."—Some correspondent may be able to supply the desired information.

Our Editorial Table.

THE ADAMS TELEMETER.

Adams & Co., Charing Cross-road, W.C.

THIS is a simple device for enabling a hand camera worker to judge of the distance of an object he is photographing. In use, the telemeter is held (as shown in the illustration) close to the eye. The tube through which the eye looks is pointed to the base of the object, towards which the eye is directed, and, as soon as the object

is sighted, the spring is pressed by the thumb. This fixes the indicator, and the distance in yards may then be read off. We have subjected the telemeter to test measurement, and find it accurate.

THE WELLINGTON FILM.

Wellington & Ward, Elstree, Herts.

THE Wellington Film makes its appearance at an opportune moment. Readers of our pages during the last twelve months will have noticed that we published communications from several correspondents pleading for the reintroduction, at the hands of manufacturers, of suitable paper coated with gelatine emulsion, for negative purposes. The Wellington Film may, in many respects, be accepted as an answer to these requests.

The characteristics of the Film are such as will probably attract considerable popularity to it, for we may say at once, as the result of the few trials we have so far been able to make with it, that it is exceedingly easy to manipulate. It may best be described as a fairly stout film of gelatino-bromide, supported by a paper backing, from which, after development, it is readily stripped by the mere device of turning back a corner of the film from the support and gently drawing it off the paper. Nothing could be simpler. Where stripping is not desired, however, the backing may be allowed to remain and the negative printed from as were the paper negatives of a decade ago.

In use: Pyro ammonia for normal exposures and amidol for instantaneous work, are recommended. The alum bath and a fixing solution of plain hypo are also advised. Here are details of the other manipulations:—

WASHING.

On removing from the fixing bath wash in running water for at least one hour.

SOAKING BATH.

On taking the negatives from the washing water, immerse them for a few minutes (five to ten) in a bath composed of:—

Formalin (40 per cent.)	3 drachms.
Glycerine	2 „
Ammonia, 880°	1 drachm.
Water	20 ounces.

The addition of ammonia renders the film more adhesive to the glass plate during drying. A further increase in the quantity of ammonia tends to expand the film, the action taking place after the film has been stripped off, and, if allowed to remain in solution, this may be advantageous in the case of over-development; by this means an enlarged negative of good printing density may be obtained.

STRIPPING.

The stripping may be conveniently started by rolling one corner between the finger and thumb. Pull off the transparent film from the paper backing evenly and gently, and, after a momentary immersion in the soaking bath to wet both sides, transfer direct therefrom to a glass plate (which has been thoroughly well cleaned with ammonia, whiting and water), and when quite dry dust over the surface a little powdered French chalk, polishing off lightly with a dry cloth. Ferrotype plates are not recommended, as the films have a tendency to peel off these during drying. Lay the film carefully hereupon, avoiding air bubbles. Do not squeegee, which is likely to distort the film, but carefully drain and allow to dry *slowly* in a *cool* place; on *no account* expose the drying film to the hot rays of the sun or to artificial heat, otherwise the film may become detached from the plate in the course of drying, thereby producing a wrinkled and cockled film.

When dry, the film may be removed from the glass plate by lifting up the corner of the film with the point of a knife, and it will be found to be perfectly plane and smooth.

Varnishing.

For the prevention of silver staining as well as to obviate any of the evil effects of dampness, the dried film may be conveniently varnished by dipping bodily into any suitable varnish which requires no heat. Sufficient varnish should be poured out into a flat dish into which a single film should be immersed; carefully drain it by slowly lifting, and pin up by one corner to dry.

We shall be surprised if the Wellington Film does not come into very general use. It is issued both as a cut film and in the rollable form. Of the latter we hope to speak, together with others of Messrs. Wellington & Ward's new introductions, on a future occasion. In the meanwhile, Messrs. Wellington & Ward may claim to have made a useful and practicable addition to the photographer's resources.

The Paget Prize Collodio-chloride Paper.

The Paget Prize Plate Co., Watford.

We have received samples of the latest make of the Paget Company's collodio-chloride paper, of which two kinds are issued, the one coated on Rives, and the other on Saxe paper. The "special C. C." is intended for professional use, and is not supplied in shilling packets. Both papers appear to be all that is desirable in a printing surface of this description, and, having regard to the charming results obtainable and the comparative ease in working it, we are not at all surprised to hear that the paper is growing in popularity.

News and Notes.

We learn that Mr. A. L. Henderson attended at the Grand Hotel, Cimiez, on April 20, to receive Her Majesty's commands.

Hackney Photographic Society.—Elementary course.—During the months of June and July a series of elementary lectures will be given by Messrs. E. J. Wall and W. E. Debenham. Subjects: Lighting; Focussing; Exposure; Development; Fixing; Intensification and Reduction; Defects in Plates; Printing.

Mr. E. Willitt, of 168, Cowley-road, Oxford, writes: "May I beg the insertion of this letter, as it may prove a caution to others? A heartless scamp, to whom I had entrusted an Optimus camera, four metal slides, a 12×8 and 8×5 rapid rectilinear lens (the latter without stops), and 7×5 wide angle, has disappeared with them, stripping me of my means of living. Should any photographer be favoured with a call, I trust they will call in police aid, in whose hands I have placed the case."

Hackney Photographic Society.—A popular lecture and demonstration of the Röntgen rays, the New Photography, will be given at the Morley Hall, Hackney, on Thursday, May 7, 1896, by Mr. J. E. Greenhill. Syllabus.—Light: General properties, visible spectrum, invisible spectrum, action on certain salts, photography, fluorescence. Electricity: High-pressure discharges, discharge in air, in moderate vacua, in good vacua, in high vacua, anode effects, cathode effects, comparison with ordinary light phosphorescence, radiant matter, light, radiometer, electric radiometer, heat radiometer, mill-wheel experiment. X Rays: Theories concerning, comparison with ordinary and cathodic rays, action on certain salts, photography, transparency. Kryptoscope: Dependent on fluorescence, penetration of the X rays. The whole subject will be fully explained, demonstrated, and results shown by means of optical lantern. Many of the experiments will consist of photographing through opaque substances, such as wood, leather, and vulcanite, &c., and of the bones through the living flesh. The chair will be taken by Mr. E. J. Wall, F.R.P.S., supported by local medical gentlemen.

Patent News.

The following applications for Patents were made between April 15 and April 22, 1896:—

Kinetoscopes.—No. 7801. "Improved Apparatus for Obtaining and Viewing Chromo-photographic or Zoetropic Pictures." Communicated by Auguste Lumière and Louis Lumière. B. J. B. Mills.

Photographic Apparatus.—No. 7809. "Improvements in or relating to Photographic Apparatus." Complete specification. G. R. Sanson.

Chrono-photographic Apparatus.—No. 7817. "Improvements in Apparatus for Taking, Developing, and Exhibiting series of Photographs." J. Oulton, W. Shaw, and R. H. Adams.

Changing Boxes.—No. 7846. "Improvements in and relating to the Changing Boxes of Photographic Cameras." R. Dobson.

Mounting Photographs.—No. 8143. "Improvements in and relating to the Mounting of Photographs and other Pictures." S. Delépine.

9.....	Borough Polytechnic	Excursion: Worcester and Ewell.

London and Provincial Photographic Association.

April 23,—Mr. T. E. Freshwater in the chair.

Mr. W. D. Welford passed round for examination two of the Continental exhibition medals.

Mr. G. W. Atkins read a paper on

Micro-photographic Reductions. [See Lantern Supplement.]

After the paper Mr. Atkins proceeded to demonstrate the process, making three exposures in all. A microscopic slide was coated with wet-collodion and exposed to a wet-plate negative of the *Ten Commandments* for thirty-five seconds. He then developed it, using pyrogallol, fixed in cyanide, and dried, after which it was placed under the microscope for examination by the members, who thought it very good. Mr. Atkins explained that there were generally a lot of wasters to one good slide produced, and every one was by no means a success. Another exposure to a negative of a house was tried, and it being a gelatine negative more exposure was necessary, that given in this case being about seventy seconds. This, on examination, was not so good. The third exposure was for eighty seconds, and was somewhat better. The focussing arrangement was explained. It consisted in reversing the position of the light, that is, to the end where the plate is exposed, and the insertion in the place of the latter of a micro slide, the image of which is focussed on a ground-glass screen, occupying the position of the negative to be reduced. Difference is allowed for between the chemical and visual focus subsequently. The micro lens is carried in a tube, sliding in an outer tube, the joint being rendered light-tight by velvet lining. The actual focussing is done with the micrometer screw, which has forty-eight threads to the inch. In answer to a question, he said the focus of his condenser was about seven inches.

The Hon. Secretary had heard that, in commercial practice, a battery of lenses was used, and the plates were cut up afterwards.

Mr. Atkins subsequently demonstrated the mounting of the slides, the covering glass being affixed with Canada balsam rendered warm, and then pressed into position.

Photographic Club.

April 22,—Mr. Frank Haes in the chair.

Mr. W. D. Welford showed two medals, one in bronze and one in gold, from the Brussels Exhibition, a replica of which was sent to every person whose work was accepted for exhibition. The medals were rectangular in shape, and of chaste design.

Mr. Drage sent a circular with information regarding the coming Convention at Leeds.

Mr. Fry distributed, on behalf of Mr. Alfred Watkins, a number of copies of the different reports and articles which had appeared consequent upon Mr. Watkins's developing competition.

The Chairman drew attention to and explained some examples of archaic lenses.

Messrs. Watson & Son exhibited one of their Alpha hand cameras. This is a very light and compact instrument, which has all the useful movements that a camera should have. It is fitted with a Thornton-Pickard shutter, with a novel attachment for discharging it, viz., an arrangement by which the pressure of the finger which relieves the catch acts against the rest of the hand, and so reduces to a *minimum* the chance of shaking the camera during the operation. The camera has an extension long enough to take one of the combinations of a five-inch lens, and is fitted with a rectilinear lens working at *f*·7·7. The price of the apparatus was stated to be 13*l.* complete.

An interesting discussion took place as to the comparative merits of triggers and pneumatic balls for discharging instantaneous shutters. The general opinion seemed to be that, for a camera held in the hand, a trigger or button was the better method, whilst for a camera upon a stand the preference should be given to the ball.

Mr. Thomas Bedding said he had been using a half-plate hand camera with a ball and tube. He had had almost total failure in securing sharp pictures until he changed his method of exposing.

Messrs. Watson also showed an example of a device which they called the "instantaneous" flange. It consists of a flange in which for the ordinary

screw thread is substituted three jaws on the principle of the universal jaw chuck. A small lever closes the jaws upon the threads of the lens screw, which is thereby instantaneously fixed into position. The device appears to be a very useful application of an old idea to a new use.

Messrs. Shew & Co. showed examples of the Xit camera. The characteristics are extreme lightness and compactness, a whole-plate camera fitted with a Thornton-Pickard focal plane shutter weighing as little as one and a half pounds. The apparatus shown by this firm indicated a high degree of mechanical ingenuity.

Mr. J. E. Hodd showed, on behalf of Messrs. Spiers & Pond, a miscellaneous selection of the more recent novelties as follows: Tyler's new vertical fixing bath. This is made in papier-mâché with six separate dippers holding the plates in such a way that they can be taken in and out of the fixing bath without soiling the fingers. It is an excellent device. An adhesive film-holder made by Marion. Although not exactly a novelty, this seems likely to fulfil a useful purpose. Considerable interest was evinced by the members in the use of Marion's sensitive finger covers. Mr. Hodd was good enough to permit the members to retain some that he passed round so that they might try them in actual use, and report at the next meeting. Lancaster's new slide, Mr. Hodd said, was suitable for films or plates. It is made of thin sheet iron and celluloid, and is very light, and cannot be said to be high-priced at 2*s.* 6*d.* Rubber tripod toes and a new portable developing lamp, in which Russian iron is substituted for the "odoriferous" Brunswick-blacked tin, were also shown. Mr. Hodd completed his exhibit by showing the Midget hand camera with a new device for magazine changing. He said that the camera, which was suitable for plates or films, could be loaded in three minutes, and he demonstrated in a deft manner that it could be unloaded even more quickly.

Brixton and Clapham Camera Club.—April 21, Mr. J. W. Coade presiding.—This was an "open" meeting, it being considered desirable to hold such, to enable less experienced members to speak of their photographic difficulties, with a view of eliciting information which would assist them out of the same. The result was entirely successful, the question-box being freely used and the replies and subsequent discussion of much interest.

Croydon Camera Club.—

How to Make Stereoscopic Photographs.

Mr. G. W. Watson gave an illustrated and succinct description of how to proceed in the making of a photo-stereograph on Wednesday, the 22nd ult., at the Croydon Camera Club, to a full attendance of members, who followed the lecture with considerable interest. Mr. Watson, having sketched the optical points connected with binocular vision, explained how that stereoscopic pictures are practically impossible except by the aid of a camera. For obtaining stereoscopic negatives, *i. e.*, twin views taken from two points about three inches apart, Mr. Watson stated an ordinary half-plate camera could easily be adapted, two ordinary landscape (single) lenses of approximately identical foci being used; or, in some instances, a quarter-plate camera may be employed, moving the camera between the first and the second exposure. An attachment is sold for a few pence by Messrs. Butcher, of Blackheath, which shifts the camera the necessary number of inches to obtain stereoscopic effect when the resulting prints are viewed through the stereoscope. Printing frames, cutting shapes, and various other accessories, which, if not absolutely needful, are exceedingly convenient, were shown and described. A large collection of stereographs, made by the lecturer, were displayed by means of different forms of stereoscopes, and afforded much pleasure as well as instruction. In further illustration of the subject, a number of stereoscopic transparencies were projected on to the screen by means of a biunial lantern, which was kindly provided at short notice by Mr. Alfred Underhill, who handled it with his well known efficiency. The system adopted was the one lately introduced by Messrs. Newton & Co.; the two component stereoscopic slides were respectively coloured green and blue, and were so projected that the red image fell upon the screen a little to the right of the green one. The audience being provided with tinted glasses, so that the right eye looked through red glass and the left through green, the two pictures upon the screen are merged into one, the green and red images becoming as it were mingled, so that the mind receives the impression of a black-and-white stereoscopic view of the ordinary kind. Amongst the members present, many were unable to accomplish this necessary mental synthesis, not so much because of any radical defect in the system, but because, besides a certain proportion of individuals who cannot at all, or can only partially, see pictures with stereoscopic effect, many people, through deficient colour-sensitiveness of the eye, find that the red or the green fails to properly impress the retina.

Petition to Parliament.

A proposition made by the President that the Club should draw up a petition for presentation to the House of Commons in favour of granting amateur photographers the right, under suitable restrictions, to photograph pictures, prints, and other objects of art or interest, in any of the museums and galleries under Imperial control, was unanimously adopted. Such petition will be at once drawn up, and members are requested to lose no time in appending their signatures thereto.

Hackney Photographic Society.—April 21, Mr. E. Farmer presiding.—Reports of the West Drayton and Snaresbrook outings were given by the Excursion Secretary. Work was shown by Messrs. Collins, Wilks, and Hensler. Mr. Hudson showed a new twin-lens hand camera of his own construction. Announcement was made by the Hon. Secretary of the details of arrangements for the forthcoming demonstration and lecture on the X rays, to be held at the Morley Hall, on May 7, by Mr. J. E. Greenhill.

North Middlesex Photographic Society.—April 20, Monthly Instruction Evening, Mr. Smith in the chair.—Mr. Cox gave a report on the outing to Hale End on April 18. Mr. Child Bayley then proceeded to give his demonstration on

Backing Plates.

He said that it ought rather to be called the "cure of halation," as there was nothing to learn in the actual coating of the plate with backing. He explained how part of the light, say of a church window or a bright point in falling upon the film of bromide of silver, which is translucent, was partially absorbed, the rest passing through, some passing right through the glass, this upon development appearing as halation. In connexion with this, the halo sometimes seen round a window was due to the illumination of the dust particles in the air, although this was sometimes exaggerated on development, but could not be called true halation. To get over this, a substance having the same refractive index as the glass, and having a non-actinic colour, is applied to the back of the plate, which prevents this reflection, and practically renders the reflecting surface non-existent. Caramel has this property, and is the basis of most backing mixtures. Collodion stained with aurine is also effective. Another method of minimising halation consists in staining the film itself, and for this reason isochromatic plates give less halation than ordinary, owing to the dye they contain. Another method, the subject of a patent, consists of interposing a film coloured with permanganate of potash between the glass and the bromide of silver. He passed round several plates coated with various backings, also a piece of plain glass coated, and it was seen that the reflection of the gas flame almost totally disappeared where the backing had been applied. In reply to a question from Mr. Smith, Mr. Child Bayley said that a quick development with a strong developer tended to show less halation than a long development or a weak one. Mr. Wall asked if backing decreased the rapidity of the plate. Mr. Bayley said that this was the case theoretically, and it was borne out in practice. He then proceeded to make some caramel, having deferred it till the end of the evening owing to the unpleasant fumes given off. It consisted in heating powdered sugar with constant stirring in a saucepan over a gas jet, to a temperature of about 405° Fahr. for about ten minutes, the sugar gradually melting, darkening in colour, and boiling up. When it no longer tasted of sugar, it was about done. If the temperature rose much above that mentioned, or it was too long heating, it was carbonised and spoiled. He boiled some caramel in water and added some red ochre, a little spirit to make it dry quicker, and some gum water to make it dry harder and prevent powdering. He then coated a plate with some that he had thus prepared, and passed it round for inspection.

April 27, Mr. S. E. Wall in the chair.—Mr. H. W. Bennett delivered a lecture upon

Copying.

He explained the methods of obtaining equality of lighting, and showed diagrams of various mechanical sliding rests for the camera. He dwelt upon the necessity of the object copied being parallel with the screen, and the method of securing this, the advisability of removing the lens and screen and examining for reflections, especially when copying oil paintings. He also pointed out the methods of correcting the defects arising from the use of single lenses, and the misuse of the swing back, and touched upon many other matters connected with his subject. An interesting discussion followed, in which Messrs. Pither, Mattocks, McIntosh, Cox, and others joined.

South London Photographic Society.—April 20, Mr. F. W. Edwards F.R.P.S., in the chair.—Prints from negatives taken at the Easter excursion to Chichester were shown. Mr. Nahum Luboshez, of the Eastman Photographic Materials Company, gave a lengthy address on the working of

Platino-bromide Paper.

He first pointed out the difference between this and the ordinary bromide paper. It was essential that a developer should be used which did not stain, and left the whites of the image pure; also that it should be capable of reducing all the sensitive salts upon which the light had acted. He strongly recommended ferrous oxalate for the purpose, and the image, coming up gradually, permitted alterations in the component parts of the developer to be made to correct slight errors in exposure. One part of iron solution to four parts of the oxalate solution gave the blackest tones, but one to ten could be used to produce soft results. It had the advantage of not developing a correctly timed exposure beyond the right stage. Amidol, metol, hydroquinone, &c., could be used, but with each of them it was essential that one should be able to judge when to stop development. After fixing, the image can be toned to a beautiful brown by immersion in a solution of alum, 1 part; hypo, 10 parts; and water, 80 parts, which should be gradually raised to the boiling point.

Birmingham Photographic Society.—April 21, Mr. J. H. Pickard in the chair.—Mr. G. A. Thomas lectured on

Development of Plates for Beginners.

Touching slightly upon the theory of development, which the lecturer considered should not be altogether overlooked by the beginner, strong objection was made to the use of ready-made developers, the composition of which was only known to the makers. It was recommended to warm all solutions and dishes in cold weather, or the effect of an under-exposed picture would be the result. As it was very difficult to judge of the correct exposure in all cases, it was advisable to give what might be considered too much exposure, and resort to careful and intelligent development.

Citric acid was often very useful where very great excess of exposure had been given, as its action was to immediately stop development of the shadows, and the high lights might be built up with a strongly restrained developer.

When using porcelain dishes the developer frequently frothed up, owing to the uneven surface upon which the plate rests. This can be prevented to a very great extent by the addition to the developer of sulphite of soda. Many hints were given on prevention of halation by the use of asphalt, or burnt sienna and gum.

An interesting discussion afterwards followed.

Mr. Pickard (the Chairman) said that negatives were best intensified by bleaching with bichloride of mercury in the usual way, and after thoroughly washing should be allowed to remain in a solution of bromide of ammonium, and then redeveloped with ferrous oxalate.

Derby Photographic Society.—April 21, Mr. A. B. Hamilton in the chair.—The pictures entered for the Outdoor Meeting Competition, 1895, were exhibited, and the report of the Judge, Mr. W. England, read. The Chairman presented the awards to the successful competitors, Mr. G. Walker taking the

silver medal for a well-known view in Chee Dale, and Mr. E. Fearn the bronze medal for a carefully selected study at Weston-on-Trent. The Chairman made a presentation, on behalf of the members, consisting of a gold albert and pendant, to the late Secretary, Mr. T. A. Scotton, as a mark of esteem and appreciation for his services during the past four years. The competitions for 1896 were then announced, and the meeting concluded with a paper, entitled

NOTES ON LANDSCAPE,

by Mr. F. L. Pither, ably read by Mr. T. Walker. The outdoor meetings of the Society will take place on May 30, June 20, July 25, August 22, and September 12.

Liverpool Amateur Photographic Society.—There are few places in the immediate neighbourhood of Liverpool where a more enjoyable Saturday half holiday can be spent than the district between Bromborough village and Raby Mere, and the artist, either with brush or camera, finds abundance of work in the picturesque lanes and the old ponds with reedy margins and dark water that reflects most perfectly the twisted oaks which overhang the banks; and Saturday's excursion of the Photographic Association was most successful, for nearly one hundred and twenty negatives were obtained by the members of the party, who numbered about twenty. The walk through Dibbinsdale was greatly enjoyed, as also was the excellent tea provided for the party at Mill House, Raby Mere.

Kilmarnock and Ayrshire Photographic Society.—April 18, Mr. J. Mack Wilson presided.—A limelight exhibition of slides was held. A magnificent series of views of interiors of English cathedrals and of the Royal Mausoleums was shown. The views had been taken on Thomas's antihalation plates, and certainly showed the advantage of using these plates for interiors. Mr. J. R. Hunter, architect, Ayr, showed slides, illustrating the beauties of architecture in the ecclesiastical buildings of Somersetshire. The President, Vice-President, and several other members showed slides.

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

THE COLOUR OF NEGATIVES AND RETOUCHING.

To the EDITORS.

GENTLEMEN,—The article on colour of negatives and retouching them in last week's JOURNAL opens up a subject not without interest, especially the colour of negatives and their effect upon the eyes. Classing negatives, so far as colour is concerned, under two headings, blue grey and yellow stain, the slightly stained negative is more soothing and pleasant, and does not tax the eye of the retoucher as does the cold blue-grey class of negative, or, rather, that is my experience.—I am, yours, &c.,

J. A. MOORHOUSE.

18, *High-street, Sutton, Surrey, April*, 21 1896.

TRAILL TAYLOR MEMORIAL.

To the EDITORS.

GENTLEMEN,—Subscriptions to the Memorial Fund are still coming in, but, naturally, more slowly than when the list was first opened. We are looking forward to a very hearty response by the Photographic Societies to the appeals made to them in your columns by Messrs. R. P. Drage, P. Everitt, and others, and, since, in a letter addressed to each Honorary Secretary by myself. I have a few societies' subscriptions already in hand, and have information that the matter is under consideration by the councils of several others, and that in many cases subscription lists have been opened.

A generous offer has been made by the Autotype Company to subscribe ten guineas to the fund, conditionally upon the amount subscribed reaching £500, which ought to be of assistance in drawing subscriptions.—I am, yours, &c.,

ALEXANDER MACKIE.

"PHOTOGRAPHIC ILLUSTRATIONS."

To the EDITORS.

GENTLEMEN,—The comments in your "Ex Cathedrâ" of the 24th and 17th ult., will certainly do good, in deterring the producers of bad works in this line (for it must honestly be admitted that some shocking abortions in half-tone have appeared in the illustrated press, but it will as surely spur on those who have the artistic ability for better work to meet the requirements of the illustrated press and book publishers). I have (admittedly) produced some fairly good work, which yourselves (and the late Mr. T. Taylor, and others) have noticed as being "fine artistic work" productions, as composite combinations of photographic and fine-art manipulations for illustrating purposes. The writer of the article in the *Publishers' Circular*, noticed in your "Ex Cathedrâ," is mostly right in his remarks for special knowledge, for this special line of work is really very necessary; but, with such knowledge, it is assuredly possible that high-class work can, and will continue to, be produced, let the lay press say what it may against it; for I know, from many years' practical experience as a scenic artist, stage manager, draughtsman, and photographer, that a thorough, all-round study is necessary before the results suitable for the highest class of illustrations can be produced. But to men of all-round qualifications splendid results can be produced by the half-tone photo-process, given that the originals are specially produced with this motive in view and that the blocks are as carefully produced therefrom.

Art editors and publishers nowadays are too wide-awake to their own interests to throw aside a process of production that has already given them so wide a scope for the saving of time and money, in spite of all the twaddle that has or can be said. It cannot honestly be denied that some very beautiful results have been produced as pictorials by photo-art work. The writer you have quoted honestly admits that "the figures were arranged with considerable effect." Here is the keynote for the art editors and publishers for what to avoid. They will, in future, refuse "combination" productions, wherein such "penny-gaffy backgrounds and scenic paraphernalia appear." But they will assuredly heartily welcome and accept good combination work, showing artistic, component harmony in the entire production, and with such I shall, at all times, be pleased to correspond upon this subject.—I am, yours, &c.,

PHOTIQUE-ART.

"AN AMUSING REPLY."

To the EDITORS.

GENTLEMEN,—Mr. "Richardson Brown" is, I think, in error. The only "hand-book" of mine yet published is on *Lantern Slides* (P. Lund & Co.), and a careful perusal thereof, of both first and second editions, brings to light no such sentence as your correspondent quotes. To my recollection I never used sulphate of soda (Glauber's salts) in a developer in my life, and I am quite sure I never suggested its use to any one else.

Pressure of other business prevents me looking more deeply into my various proofs and MS., but I am sure the above statement is correct.—I am, yours, &c.,

J. PIKE.

7, *Church-drive, Carrington, Nottingham.*

THE RIGHT TO PHOTOGRAPH.

To the EDITORS.

GENTLEMEN,—May I draw attention to the fact that the Croydon Camera Club is preparing a petition for presentation to the House of Commons, asking that amateurs may be permitted to photograph objects in the national collections? I would suggest that other photographic societies should adopt a similar course.—I am, yours, &c.,

HECTOR MACLEAN.

ASSISTANTS AND THEIR GRIEVANCES.

To the EDITORS.

GENTLEMEN,—I heartily endorse Mr. Randall's remarks in your last issue that all assistants owe a heavy debt of gratitude to the late Mr. Traill Taylor and you, sir, for the kind sympathy with every well-directed effort to improve the condition of photographic workers—to enable them to work in sanitary workshops, to obtain fair wages and reasonable hours of employment, and for opening your columns on behalf of those assistants who have legitimate grievances.

I quite agree with "North Wales Operator" and Mr. Randall that the time has arrived when something should be done to make the sweated assistant's life a little brighter. As one who has served for a few months and seen the inner working of this large firm of cheap photographers, and who has been in touch with nearly every assistant employed by this firm, will you allow me space to say that the real grievances are bad pay, and a great deal less of that which the two heads of this firm are past masters in, *i.e.*, bullying, also the want of holidays, which is very keenly felt by all hands. Now, gentlemen, all work and no play makes Jack a very dull boy. Althongh the heads of this firm take an annual holiday, it never occurs to them that their assistants should also have a due share of recreation and relaxation after a round of monotony terrible to think of.

True their studios close early one day, but this is only a farce. The operators, as already pointed out in your columns, stay long after that hour shut up in a close ill-ventilated dark room developing; the nerve of the assistant is really nothing. Surely operators, &c., who have to take from forty to fifty sitters a day, must need a brief holiday, which would be a source of strength to mind and body, qualifying each to resume his monotonous round of daily life with renewed spirits and restored health; yet this is denied them; it cannot be for want of money.

To stop this grinding, a union should be formed to shorten the hours of labour and regulate the relations between employers and employees, also to assist members in case of distress, through illness or want of employment. I am sure, to secure the above, all photographic workers would not object to a small contribution, say, from threepence to fourpence per week.

Should only a small number join, rather than let the matter drop, could not they amalgamate with some other union of an allied trade, and wait for development? If a meeting could be arranged after business hours, I am sure there would be a good attendance of assistants, for I want to set it down, as unmistakably as I can, that all photographic workers stand sorely in need of some means of appeal against unjust dismissal, sweating, and the petty tyranny which is carried on by some firms; and, to do this, workers should stand shoulder to shoulder to form a union to fight for their grievances. Should it be impossible to do this, perhaps some of your readers would be able to devise means which, to some extent, would relieve these grievances.

It is lamentably true that these assistants are afraid to lift a finger in their own behalf. They are content to put up with any form of treatment, for they know there are more recruits on the firm to snap up their places if they should "kick." With two or three exceptions, the operators are mere lads, bred and born in the firm, who, after serving a few months, pick up a slight knowledge of operating and retouching, and are drafted into the first vacancy which occurs with the magnificent salary of 20*s.* to 25*s.* per week. It is with this class of assistants, who have no previous experience, the firm like to deal. At several studios where I was sent to retouch, the assistants dread the time to come when one or the other of the heads of the firm arrive to check the negatives, make up the books, and commence bullying should the takings for the day not please them.

In conclusion, will Mr. Randall kindly state in what way sufferers are to come forward and state "who are the wrong doers?"

Apologising for the length of this letter,—I am, yours, &c.,

A Retoucher of Thirty Years' Standing.

Answers to Correspondents.

*** *All matters intended for the text portion of this* Journal, *including queries, must be addressed to* "The Editors, The British Journal of Photography," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* Henry Greenwood & Co., 2, *York-street, Covent Garden, London.*

Stocks' Lamp.—H. Becker says: "Please will you be so kind as to tell me the address of the maker of Stocks' patent lamp for projection (four wicks)?"—The address is W. Stocks, Rye, Sussex.

"The Black List."—J. A. Randall. This ceased to exist some four or five years ago. Our experience was that it exercised a great moral effect—at any rate, we have not found cause to continue or revive it.

Copyright.—Doubtful. If the engraving you desire to copy and publish was published in 1697, you can copy it without let or hindrance. If it were a recent reproduction of the work, the case might be different.

The "Photo Gazette."—Alex. Grant. We cannot remember the particular number referred to. Call at the rooms of the Royal Photographic Society, 12, Hanover-square; the Secretary will probably allow you to consult a file.

Starch.—T. Rogers. It is white starch that should be employed for mounting photographs, not the blue. There is a kind known as "moulding starch," which is admirably suited to the purpose, but we think it can only be had from the manufacturers direct.

Clearing Bromide Enlargements.—E. Mentor asks: "Do you consider that clearing bromide enlargements with hydrochloric acid has any injurious effects upon the enlargement?"—Yes, decidedly, unless the acid is thoroughly washed out of the paper before they are put into the hyposulphite of soda fixing bath.

Cracked Prints.—R. E. C. The cracks are caused by the prints being allowed to curl up as they dried; then, when they were flattened out, the albumen cracked as seen. This is no uncommon thing with thickly albumenised paper. The remedy is to dry the prints between blotting boards, so that they are kept flat the while.

Stamp Portraits.—S. Burrows In taking postage-stamp portraits it is usual to take them with a number of miniature lenses—four or five, or up to a dozen or more. If only one lens be used, then, of course, the plate must be shifted after each exposure to get the number of portraits on the plate. The same end will naturally be obtained by moving the lens instead of the plate, but then there must be a number of partitions in the camera corresponding to the number of portraits taken, the same as if the work were done with a number of lenses.

Pathology.—Sawbones asks: If there is any real advantage is using orthochromatised plates in photographing surgical and medical subjects. He has, he says, used both kinds of plates—orthochromatic and ordinary—and finds no difference whatever between them. He says further that he has not employed a colour screen, as he is told that that is not necessary. We should recommend that the experiments be repeated with colour screens of different tints, according to the subjects, then a decided advantage in favour of the orthochromatised plates should accrue.

Washing Prints.—W. Hawkins writes: "What is the proper time to give prints in washing, after fixing? Some say, Wash all night; others say that gelatine prints will not bear more than an hour's washing without their going yellow; which is right?"—The prints should be washed until all the hypo salts are eliminated, and the quicker that can be done the better for the stability of the prints. If prints on certain papers will not stand more than an hour's washing without deterioration, they must be carefully attended to the while. Prints, however, can be as effectually washed in an hour or two, with careful attention, as with many hours soaking.

Use of Dark Rooms.—R. C. complains that, "on applying to three professional photographers in a country town, they refused him the use of a dark room to change and develop a few trial plates in unless he paid, what he considers, an exorbitant fee for the privilege, although none of them had sitters at the time. He says this is hard upon amateurs, and churlish on the part of professionals."—Every one has the right to fix his own terms; and, if, what we have often heard of the behaviour of some amateurs when they have obtained the use of a room be correct, we are not at all surprised if, in some instances, they are high. Some we know will not allow the use of their rooms on any terms whatever.

Toning Difficulty.—J. T. P. "The present is to trouble you respecting a difficulty I am in as to getting a good toning bath for albumen paper to produce good black or purplish-brown tones. Of the three specimen prints I enclose, No. 1 was toned with the usual acetate bath, and Nos. 2 and 3 with the carbonate bath. The prints were well washed, then put in a bath of washing soda and water (half ounce to the pint) to neutralise the acid, again well washed, and then toned. Chalk had previously been added to the gold, as usual, yet the toning was very slow indeed, and, as you see, the tone anything but desirable, and when they reached a certain point they would not alter at all in tone. Prints from other negatives were done at the same time, but they all turned out, unfortunately, with the same rusty tones. The only thing I omitted to use was distilled water. Would this account for it? The bath was heated to about 70°. If you can possibly assist me as to the cause of failure, I shall be greatly obliged, as I have always failed to obtain good tones with albumen paper?"—As our correspondent does not tell us anything about the preparation of the albumen paper, the salting of the albumen, sensitising, &c., we can give very little information of value on the subject. We may say, however, that quite as much, or more, of the tones, depends upon the negatives as the paper or the toning baths. With suitable negatives the acetate or the carbonate toning baths will yield the tones desired. If ready-sensitised paper be used, we should suggest that another brand be tried with the same negatives.

Doubtful Conduct.—Painting writes as follows: "Can you kindly give me an idea how to act under the following circumstances:—A man I have been acquainted with for some time, who is a portrait painter, agrees verbally to paint portraits for me, at a fixed charge, from my negatives. He has done several for me, and I have paid him for them. I got an order for a painting from one of my negatives of a child that had been dead some months. He did the painting, and I paid him for it when he brought it home. As it was a good subject, he casually mentioned that he thought he would paint a larger size also; this was to be a specimen of work. I have never seen this one. He brought home the small one that I had ordered, and, as he happened to be going in the locality where the customer lived, which is about sixty miles from here, I entrusted him with the small picture that was ordered to be taken home, thinking that if any alterations were needed he could make them. It was also arranged between us that he should take the large picture as well, and I told him, in the event of the customer wishing to purchase it, what price to ask. He had never seen the customer before. It appears that the customer did purchase it, as I sometime afterwards discovered, and also paid him the full amount I had told him to ask for it. I should much like to know if you think he has a right to act in this manner. As he refuses to have anything to say in the matter, and has appropriated the whole of the sum the lady gave him for the picture, can I claim through the County Court or otherwise my profit on the same, as it does not seem right that I should have to conduct my business and take negatives for his use? Trusting you will favour me with a reply?"—The man has behaved in a very unhandsome, not to say "dirty" manner. You also did an unwise thing in entrusting such a man with your customer's address. We do not see that you have any remedy at law in the matter. The only remedy that we can suggest, which has already, no doubt, been adopted by you, is not to entrust the man with any further work. You might further mention the matter to your photographic friends. Such a man as that is not to be trusted with work for the profession.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1879. Vol. XLIII.—MAY 8, 1896.

Contents.

EX CATHEDRÂ.

The Process Year-Book for 1896, which has just been issued by Messrs. Penrose & Co., of Amwell-street, is a notable book. It contains nearly a hundred illustrations in line, half-tone, collotype, photogravure, and colour, and many articles by qualified writers and experimentalists to whom the process man may safely turn for help and guidance in his doubts and difficulties. It is a production of which editor, publishers, and printers may be proud—indeed, to the printers, Messrs. Allen & Carruthers, of the Cranford Press, Chiswick, distinct and special praise is due for the unusually excellent manner in which both type and blocks have been rendered.

* * *

To those interested in process work Messrs. Penrose's volume will be welcome, as conveying a good idea of the strides that have recently been made in half-tone and three-colour work. Our pleasure, however, in turning over its handsome pages is alloyed by the reflection that the apathy of photographers has forced what is virtually a new industry to appropriate work which, from its very nature, photographers should not have allowed to pass them. But process work, in all probability, is yet in its early stages, so that, to the photographer who decides to take up some branch of it, the opportunity may still be available. As contributors to the volume we are mentioning, we note the names of Max Levy, Vidal, Dallas, Henry Blackburn, Wilmer, Wall, Denison, W. D. Richmond, E. S. Shepherd, &c. The illustrations are by the best known firms.

* * *

The Hackney Photographic Society has been endeavouring to induce the great railway companies to grant to amateur photographers some concessions in the matter of reduced fares on photographic outings. The companies decline, however, to entertain the idea. Not being followers of the gentle craft, we are not in a position to precisely understand why anglers were originally granted privilege travelling tickets, and therefore we hesitate to plead that photographers should be placed on the same footing as the fishermen.

* * *

Cheaper fares would probably lead to increased attendances at photographic outings, so that the companies would conceivably not suffer by the concessions. On the other hand, we must assume that there are good and cogent reasons for the refusal of the companies to give way. In an interview with some railway representatives on this very subject some few years ago, it was stated, if we may trust to memory, that the companies were actuated in their refusal by the idea that the privilege tickets, though ostensibly to be used for strictly photographic purposes, might very easily be availed of for ordinary travelling, pleasure, or business objects, a factor which possibly need not be reckoned with in the case of anglers, who are restricted as to localities and seasons, thus making abuse of the concession difficult.

* * *

Our contemporary, *Nature*, moved by some sharp comments in the daily press with reference to the fact that, in a recent patent dispute, eminent scientific experts figured as opposing witnesses, with the result that, though the question to be determined was simply one of chemistry and chemical history—matters of pure science, in fact—there was a remarkable conflict of testimony, has again suggested the abolition of the expert witness, and the institution of a system whereby a scientific expert should not be called by a particular side in a case, but should be nominated by the Judge. Under such a

system, it truly remarks, no question of bias could be raised, and science would not be scandalised from time to time, as it is now, by those who are content thus to trade on their scientific reputation.

* * *

Universal endorsement will assuredly be given to our contemporary's suggestion. The inducements to an official expert to depart from accuracy would be removed, so that the truth would be more readily arrived at than under the present system where it appears that, the more eminent the witness, the greater is the influence upon his testimony exercised by the amount of his fees. There have been cases in photography that have called for the intervention of "scientific experts," whose opinions have been not less contradictory than in the instances quoted above, which persuade us that it would be a good thing if the unofficial expert witness in photographic disputes were also abolished. We have in mind a case in which, a year or so ago, certain markings on a photograph were said by some expert photographic witnesses to have been produced in a particular way. Some equally expert photographic witnesses were in attendance, to prove that the markings were due to totally different causes. It was a merciful thing for expert photographic testimony that the case, half way through, was stopped by the jury.

PHOTOGRAPHY AT THE NATIONAL GALLERY.

The refusal of the Trustees of the National Gallery to allow amateur photographers to copy the pictures seems to be causing some little annoyance in certain quarters. Since the publication of a correspondence between the Secretary to the Trustees and one of the members of the Camera Club, a question on the subject has been put in the House of Commons. The reply given, however, does not appear to please the Croydon Camera Club, which, according to a letter in our last issue, is going to petition the House on its own account, with what results remains to be seen.

The recent correspondence brings to one's mind what was done a dozen or so years back. It will be remembered that up to about that time there were no really good reproductions of our national pictures, as a series, such as there were of Continental galleries. Then a German firm obtained permission to photograph the collection, and also the liberty to erect a studio, outside the building, in which to do the work. There was a great outcry at this at the time, and the explanation given was that the firm that had obtained the concession had given certain undertakings as to the publication of the copies, also that the reproductions it had made in the various Continental galleries, where similar facilities had been given, were of an exceptionally high order as compared with other work at that period—for then orthochromatic photography was in a very embryo state, except with that firm and one or two others. A further reason for the concession was that the copies would be widely circulated, which would be a great boon to art students.

The fact that some of the pictures had been previously photographed by a French house, no doubt, gave rise to the idea, which still seems to prevail with some, as evidenced by Mr. Craigie's letter to the Trustees, that only foreign firms were allowed to photograph our national pictures. As a matter of fact, some English houses are continually at work upon them—the Autotype Company, Messrs. Eyre & Spottiswoode, and others. The former, by the way, have for some years been privileged to hang frames of specimens of their reproductions in the entrance hall of the building. Again, Messrs. Walker & Boutall are at present engaged in photographing the works in the National Portrait Gallery for publication. This at once dispels the idea that only foreign houses are permitted to photograph in the National Gallery.

We now come to the question, just being raised, of amateurs being allowed to photograph the pictures. The pictures are the property of the nation, and the Trustees are their custodians, and are responsible for their safe keeping. They are at the same time interested in the furtherance of art and its study, and it is to this end that professional photographers are allowed to reproduce the pictures—because they will be published, and so become of service to art students and lovers of art generally. The Trustees also have in mind that the work should be well done or not at all, and we doubt much if any professional would be permitted to take photographs of the pictures unless the former were tolerably sure that the work would be well executed, and that there was a prospect of its being widely circulated. No such end is gained by the amateur photographer; he simply photographs a picture for his own amusement, and there is an end of the matter, as, beyond his immediate circle, no one sees the result, whatever may, or may not, be its merits. During the time the amateur would be at work he would, of course, be monopolising the picture from the public; and, as it was said in one of the letters that opened this question that the reproduction of pictures involves an immense amount of time, such as the professional is rarely able or willing to give, it may be fairly assumed that the amateur will monopolise the picture for a much longer time than does the professional. If that be the case, it is a strong argument in favour of the Trustees' refusal.

Amateurs ask for the same privileges as art students are accorded; but, as was explained in the reply given in the House of Commons, the cases are widely different. The latter copy the works to improve themselves in drawing and painting, but the amateur photographer could no more improve his photographic knowledge by copying a Raphael, a Teniers, or any other great master, than he would by reproducing any other oil painting. If it be urged that his object is to improve his art knowledge, then that end would be better gained by purchasing, for an almost nominal sum, one or other of the published copies, which are infinitely superior, as regards the translation of colours, to the majority of amateur productions.

One of the reasons assigned for the refusal to amateur photographers was that the galleries are now often inconveniently crowded with students, and the presence of cameras would further increase the inconvenience. We strongly suspect, however, that there is another reason that may, and no doubt does, weigh with the Trustees, namely, the risk of irreparable injury to works for which the nation has paid fabulous amounts. Removing the pictures from the walls, unglazing them, and exposing them to the air for a time; then, after they are copied, reglazing and rehanging them, even by the most careful hands, involves a certain amount of risk. Hence, the Trustees of the nation's pictures, naturally, do not care to incur this risk, however remote, oftener than can be avoided, particularly in face of the probability that it would frequently have to be repeated, with the same picture, with the amateur who is "able or willing to afford" the time and attention to the work. With the art student no such danger is incurred.

Taking all these facts into consideration, it is scarcely sur-

prising that the Trustees refuse to risk the safety of the nation's pictures for the amusement of single individuals. However, we shall see what comes of the Croydon Club's petition to the Commons—if it is ever presented.

IMPROVISING A SCREEN-HOLDER.

MANY amateurs and others commencing experimental work in half-tone etching are met by the difficulty of finding a suitable dark slide or holder in which to use the screen. The ordinary dark slides do not afford sufficient space, while the special holders constructed for this purpose are necessarily costly appliances, owing to the elaborate and delicate arrangements necessary for the accurate adjustment of the relative positions of screen and plate.

Although for real working purposes such a special holder may be said to be an absolute necessity, the early experimental attempts may be very well carried out by means of makeshifts, which entail no great expense should it be ultimately decided to relinquish the work, and yet enable the operator, with a very slight amount of extra trouble, to achieve as great accuracy as with the more expensive tools. The following description of an improvised holder may prove useful to some of our readers at the present time.

Unless specially ordered of the exact size, the half-tone screens supplied commercially are, as a rule, considerably larger than the size of plate they are supposed to represent; for instance, a half-plate screen will be nearer the size of a whole plate. This being so, either a larger size of camera should be available or the screen must be obtained of the exact size of some existing one, in which case it will be advisable, if not indeed absolutely necessary, to work with a smaller size of plate.

It is possible in some of the old-fashioned cameras that the slides, at least the double ones, will allow sufficient room for both screen and plate, together with the requisite separation between them; but this will not often be the case, so we will assume that the existing slides are not roomy enough. In order to supply the deficiency, remove, in the case of a single slide, the hinged back door, and, in the case of a double, one of the shutters and the central division, and, in the place of either, have fitted a frame carrying a central aperture a little larger each way than the largest plate to be employed. Have constructed also a carrier, by means of which the screen can be adapted to the dark slide; and in the majority of cases this will be found to occupy nearly, if not quite, the whole of the available space within the slide, so that, when the back frame is fitted in position, it keeps the screen-carrier in place, and the central opening forms a well or rebate, into which the sensitive plate can be dropped, in actual contact with the screen if desired.

But, as a certain amount of separation is always needful, this can be secured by the interposition of one or more cardboard masks, and, if these are cut from boards of uniform thickness, they will serve to definite and variable distances between screen and plate at will. This is all that will be needful if dry plates are used; but, with wet plates, some light form of mask or carrier must be provided to hold the plate, the additional masks being still used to secure variations of distance. A hinged or, preferably, a detachable back door with spring fitted to the opening will complete a holder, which, with the aid of a loose piece of ground glass, will serve at once as focussing glass as well as screen-holder or dark slide.

Photography inside a Crookes' Tube.—The mode or place of genesis of the Röntgen rays is still matter of doubt, and, in the endeavour to solve it, M. G. de Metz has taken photographs actually within the tube itself. He finds the cathode rays possess one of the properties of the Röntgen rays, in that they penetrate aluminium, cardboard, and paper, but are stopped by platinum and copper.

Mr. Espin on Fluorescent Screens.—Writing to the *English Mechanic*, he describes his success with the tungstate salt, which appears to have been very considerable. He says the tungstate of calcium screen was examined in the dark, and found, even half an hour afterwards, to be luminous; but a fresh sample taken into the dark from a gas-lit room was found to be quite free from luminosity. Esculin and quinine, which give fluorescence with the ordinary vacuum tube, are useless, he states, for the Röntgen rays.

A Novelty in Litmus.—Though no photographic equipment is complete without a book of litmus paper, more often than not termed in the printing room "test paper," as though it were the only test paper in existence, yet we are afraid that a fair sprinkling of establishments in a large way of business manage to do without it. However, those who are familiar with its advantages will be pleased to learn of a new form for using litmus which bids fair to do away with the time-honoured little book of slips. It consists of a litmus pencil, in which the tinctorial material replaces the usual graphite. The pencil, further, is red at one end and blue at the other, the use of which is obvious, as, indeed, is the value of the whole pencil. A piece of clean white paper and a stroke drawn by each end of the pencil will afford the handiest of tests imaginable. The agents are Messrs. Christy & Co., of Lime-street, E.C.

A Novelty in Magnesium Light.—Magnesium for flash or "torch" has been very popular for some time past, but ribbon or wire is very liable to "give out" just when the light is most needed, except when special precautions are taken or arrangements made. But the new method of burning seems to offer a perfect medium of actinic combustion. It consists in the "sandwiching" of magnesium powder between sheets of paper impregnated with potassium chlorate. Magnesium powder is placed between two sheets of paper, which have been pasted over with starch. The whole, when dry, forms one single sheet. Next, each side is covered with a piece of paper impregnated with potassium chlorate, and the whole covered with a further sheet of paper pasted on each side, a thick sheet, almost like cardboard, being thus produced. It may then, when perfectly dry, be cut into lengths and ignited as required. According to the *Journal of Chemical Industry*, the combination is quite safe and keeps well.

Where do the Röntgen Rays Emanate from?—M. Poincarré, criticising M. de Metz's conclusions, propounds the theory (these papers all being presented to the Paris Academy of Sciences) that the conclusions given are not correct, seeing that, he says, the cathode rays striking the aluminium or platinum screen may then go through the metallic plates. The cathode rays themselves may not possess this property. Many experimenters have been on this track. Perrin used a process of pinhole photography, and arrived at the conclusion that they arise at places where the cathode rays strike against a solid obstacle. Rowland, Carmichael, and Briggs gave the anode as their origin. Prince Galitzin and M. de Karnogitsky locate their origin within the tube a few millimetres behind the glass. In an article in *Nature* over the signature of J. J. Thompson, the writer states that the result of a series of experiments, in which he was aided by Mr. McClelland, led him to believe that they always emanated from a place where the cathode rays struck.

Phosphorescent Screens for the Röntgen Rays.—The best material for this purpose has been much discussed lately, and there may be said to be almost two schools of opinion. On the

one hand, a platino-cyanide, be it of potassium, lithium, barium, &c., is found to be unequalled; while, on the other, the calcic tungstate is said to be superior to anything. Among the upholders of the latter is Mr. Edison, who has now completed his adaptation of the original idea in the shape of an instrument to show the internal structure of the body by the Röntgen rays and phosphorescence. The method he adopted for producing the crystalline form of this salt is, according to the *Scientific American*, to fuse together a mixture of sodium chloride, calcium tungstate, and calcium chloride. Calcium tungstate, insoluble, is produced, and is obtained by washing with water, which dissolves out the soluble salts, and leaves the required body behind. Then, again, another experimenter, as already alluded to by us, prefers the natural crystals as found in a cheap mineral. Mr. Swinton writes to *Nature*, under date of April 22, comparing the platino-cyanides: "I have obtained considerably better results with a finely ground sample of calcium tungstate, prepared for me by Messrs. Hopkins & Williams. It may be used either in loose powder or made up with gum into a paste and dried." Yet other writers say that the ordinary salt is no use at all. It unfortunately happens that, so far, the crystalline salt is not an article of commerce.

PRACTICAL PHOTOGRAPHY WITH RONTGEN RAYS.*

The Coil or Transformer.

Having now fitted up an arrangement for producing a current of electricity, we proceed to transform it in character. The electric current obtained as explained would only pass through a very small fraction of an inch of air, and we wish it to have power enough to pass, in the shape of a spark, through several inches. The technical way of saying this is, increase the electro-motive force (usually put thus—E.M.F.). The greater the E.M.F. the longer the spark obtainable from the same amount of electricity. The intensity of this E.M.F. is estimated in volts; each cell of a Grove pattern has an E.M.F. of a little under two volts. When the character of the current is changed, its E.M.F. would be reckoned in thousands, or tens of thousands, instead of units. The most generally used and most readily obtainable form of transformer is that known as a Ruhmkorff's intensity coil. It is not necessary here to explain its working parts; it is sufficient to say that the electricity goes in at a few volts' strength, and passes out at many thousands volts. There is a pair of binding screws on the baseboard of the coil, to receive the two wires from the battery; and there are two smaller binding screws, usually at the upper part of the instrument, for attaching the wires that take the transformed current out of the instrument. Any one purchasing a coil would have its working described by the seller, so that it would be filling unnecessary space to give those details here, slight though they are. But a particular caution must be given, never to touch one of these screws (the terminals) or even a silk-covered wire, passing from them, with the hand; a very severe shock would be felt, even with a small coil, while, if both terminals were touched at once, the effect would be very serious, and might possibly be fatal, especially with a large instrument.

It may here be noted that it is better to use insulated wires for the current from the battery (the primary current), and essential to do so with the current from the coil (the secondary or induced current). It is very difficult to avoid at all times touching the wires accidentally and receiving a shock; and, besides, the current would be weakened if bare wires were used, and could not conveniently be led away with uncovered wires, as it would strike to external objects and be diverted.

These Ruhmkorff's coils are obtainable of a variety of powers, from those giving a spark of a quarter of an inch to others of three or four up to twenty inches or more. The longer the spark, the higher the price. The battery power has to be proportioned to the strength. Messrs. Griffin, of Garrick-street, who have made me a new coil which sparks beyond the guaranteed distance recently, have been so good as to make a special series of actual trials for me, in order to ascertain practically the safest and most suitable battery power for various sizes of coils. Though it applies to their own instruments, it would, no doubt, be about the same for other makers:—

Coil to give in Air a Spark of	Groves' Cells Needed,	
1 inch	Three	1 pint.
2 inches	Four	1 „
3 „	Five	1 „
4 „	Six	1 „
6 „	Five	1 quart.
8 „	„	1 „
10 „	„	1 „

The Crookes' Tubes.

We are now ready to turn the electricity in these famous bulbs, and the next step is to fit them to the coil. Before doing this, a brief explanation of what a Crookes' tube is may be desirable. Many years ago, one of the most popular exhibitions of electricity was the passing the induced current through a tube or bulb greatly exhausted of air or other gas. The tube had a piece of platinum wire fused to each end, and a current that, as a spark would only pass through, say, an inch of air, would pass through several inches when the gas was rarefied. In the course of his molecular investigations, Mr. Crookes experimented with such tubes with greatly increased rarefaction. The visible glow throughout the tube gradually diminished, till, when a certain point of exhaustion was reached, the current would scarcely, if at all, pass, and the uniform glow was succeeded by a luminosity at the cathode pole. Emanating from this pole were certain remarkable radiations, one property of which was the cause of the Röntgen rays.

Before attaching a tube, the current should be turned off by means of a little adjunct to the coil termed the commutator. And this shutting off the current should always be done before in any way touching or altering the secondary wires. Quite apart from the question of the pain of a shock, it might easily cause the hands to jerk and disarrange or break the valuable tubes. The further—and indeed, the original—use (whence its name) of the commutator is to reverse the direction of the current.

As to the tubes themselves, their variety is bewildering; what with dealers' and actual makers' patterns, it will be difficult to effect a choice. Quite recently Mr. Gifford, one of the earliest and most successful workers in this country, writes to *Nature* that he has obtained the best results with the earliest shape of tube he tried, while the bulk of other writers recommend a so-called "focus tube." Though Mr. Hicks has kindly made for me to try one of the form Mr. Gifford recommends, my own preference is for a focus tube. The pattern devised by Mr. Jackson gives decidedly the sharpest results, but, in my experience, needs more coil power than the other cheaper form almost cylindrical in shape. Mr. Hicks, the original maker of Crookes' radiometer, makes about eight different patterns of tubes; of those I have tried the greatest success has been with his focus tube of truncated cone form.

The first thing to be done is to fix the Crookes' tube in a steady position, which can be done by any extemporised holder, or by the aid of a laboratory tube-holder. A certain amount of firmness is desirable, for, though it may be suspended from a loop at the end of one of the secondary wires, in which case the latter must be secured to a holder, and the loop be close to the support, it is most desirable to prevent any swinging. If the tube is not stationary, the rays are naturally emitted from a larger area, and such an object as a hand will, in consequence, have the bones represented less sharply, through the penumbra being wider.

The tube being fixed, and one end connected with one terminal wire, it only remains to attach the other terminal to the second electrode of the tube, and turn the commutator so as to allow the current to pass. Immediately the luminosity in the tube becomes visible the green glow of the cathode should be at the wide circular metallic disc. If it should not be so seen, the current should be reversed by giving the commutator a half turn, when the glow will be transferred to the disc, which is now the oft-quoted "cathode," whence the rays have their original cause, though where they actually start from is still not decided. The cathode rays seem first to need to impinge upon some substance before the Röntgen rays are obtained. It is stated that Edison, by means of a long metal tube

* Continued from page 276.

and a fluorescent screen, has tried to locate them, and found them to come from all parts of the vacuum tube.

It is necessary to give certain cautions to safeguard the tubes.

First, it must be observed that the two loops of thin wire fused into the tube must be most carefully treated, or they will either be broken off short, or the glass tube at the point be split or cracked, an event which would ruin the tube by the gradual inflow of air. I can speak feelingly on this point, for I had a magnificent collection of the old vacuum tubes, nearly a score in number, and I lent them to a scientific friend, whom I thought I could safely trust to handle them with care. When he returned them, nearly every tube was ruined from either this cause or another which I will mention.

Secondly, if the tubes be not carefully and sufficiently attached to the secondary wires, it may happen that one wire will spring away, and, if in springing the uncovered end of the wire should touch, be it ever so lightly, or approach at all closely the walls of the bulb, it is very probable that a spark may pass from it to the tube, and, if it does, the tube is irretrievably damaged, as the spark would pierce a microscopic hole, which would let in the outer air. One of the Crookes' tubes I have been experimenting with "gave out" in the middle of an exposure for no apparent reason. I can only imagine that a spark passed from the supporting wire to the glass, and thus pierced it.

The deduction from this recountal is obvious. The leading wires should only be uncovered for a very slight distance from the loop that attaches them to the tube, there will then be little danger of "sparking."

In attaching the wires to the tubes they will be found to behave in a most refractory manner, springing away and straining the tube electrodes when threading them. This is best avoided by using covered wires as thin as possible, not thicker than No. 24 gauge, and they may be bent into a spiral by wrapping round a long pencil, which is then removed. A wire so shaped has less spring in it. It will avoid strain if the end of the wire have a loose link of covered wire, making a sort of chain.

There is nothing now to be done but to place the object to be photographed upon the sensitive plate. This should be placed not in a dark slide, but inside a bag of three-fold black paper, and the object to be electro-sciographed put upon the paper. Now, though it is difficult to fix upon the exact point of area of radiation, it is certain that, the further removed the tube is from the object, the sharper the shadows will be, and, if the power of the tube sufficed, a distance of twelve or eighteen inches would enable the shadows to be beautifully clearly defined. This, however, is not a very practicable distance, for it has been estimated that the actinic action decreases about as the square of the distance, so that for twelve inches the exposure needed would be sixteen times as great as at three inches.

In taking electro-sciographs of the hand or foot, the position of the tube must be regulated by what point is most likely to be needed in the sharpest definition. If the tube be suspended over the knuckles, the division between the bones will be clearly shown; if over the wrist, it is obvious the rays will pass across the separating space, and no line between the finger joints will be perceptible. The further the tube is removed the less, of course, do these remarks apply.

Again, it will be found that some hands will not lie flat on a plane surface, the fingers will spring up and form a shallow arch. Clearly, the bones would not be so sharply defined. If it be a case where sharp definition is wished for, the hand should be bandaged flat to the plate. The rays will pass through the bandages and act on the plate as though they were absent.

A word or two about price of apparatus may be useful. A recent estimate of the Editor, in reply to a query as to the cost, puts 23*l.* as the expense of an outfit. For that sum a very superior outfit can be obtained, and a very good one for much less. I have three coils, and I find that from Griffin's giving a four-inch spark, though nominally only a three-inch, capable of very good results. Its price was 9*l.* A battery of five Grove cells and stand may be put down as 45*s.* Hicks' price for a focus tube, 25*s.*; wire leads, acids, and mercury, say, another 5*s.* Total, under 13*l.*

I am particular in giving my own experience, as all the facts and prices may be relied upon; and, as Röntgen-ray work naturally falls into line with usual photographic practice, I am hoping that what I have written may be found useful by brother practitioners. Any point that I have not made clear I shall be pleased to elucidate *through the columns of this Journal*, and not by private letters to unknown correspondents. As I have before narrated, I have suffered, and thanklessly so, much loss of valuable time through queries from all parts of the world, sent to me by post from perfect strangers, that I have to make a point of declining to reply except to personal friends.

G. Watmough Webster, F.C.S., F.R.P.S.

CARBON OR AUTOTYPE PRINTING.

[Newcastle-on-Tyne and Northern Counties' Photographic Association.]

There are so many printing processes from which to make a choice, that the amateur photographer is puzzled to select the best from the multitude. In the bulk of these printing processes the image is formed by the action of light on a salt of silver contained either in albumen or, as now more generally used, in gelatine. These silver prints, if very carefully made, and very thoroughly fixed and washed, will last for years; but how often do we see prints made in this manner showing signs of fading and the whites going yellow. The silver salts contained in the paper are so sensitive to the action of light, dampness, fumes of sulphur, &c., that we can hardly class silver printing amongst the more permanent processes.

In my opinion, having tried nearly every process of printing, there are only two ways of making a really permanent picture. The first is the platinotype process, and the other is the autotype or carbon process. Of the two the platinotype is the easier and more quickly done, but the range of tone is limited to black and a very doubtful sepia tint. But the great enemy to platinotype printing is dampness in the air. The paper has to be kept in tubes containing dried chloride of calcium to absorb moisture, and, if printed on a damp day, the picture comes out flat and completely spoiled. In the carbon process you have none of these drawbacks; you can procure the tissue either in the sensitive or in the insensitive state, and of a great many different colours and shades of colour. Those most commonly used are engraving black, warm black, sepia of different shades, green for sea views, standard purple for portrait work, red chalk, and various shades of brown and chocolate are also obtainable.

Before describing the manipulations required to make an autotype picture, we will consider, in a few words, the action of light on the tissue. When a solution of gelatine is mixed with a solution of bichromate of potash, and exposed to light, the gelatine is turned into an insoluble compound. The autotype tissue is simply paper coated with gelatine in which is impregnated the colouring matter in an exceedingly fine state of division. The tissue is sensitised in a solution of bichromate of potash, and, when dry, is exposed under a negative. The light acts through the negative, and, as more gets through in some places than in others, you get the tissue rendered more or less insoluble, through all the gradations of the negative.

In the year 1864, Mr. Joseph Swan, of Newcastle, following on the lines of previous experimenters, succeeded in working out the first practical method of carbon printing. He took out a patent for the process, which was briefly as follows: A sheet of glass was coated with a film of collodion, and then, with the pigmented gelatine, this film of gelatine collodion, when dry, was stripped from the glass and exposed under a negative, collodion side next the negative; after exposure the film was coated with a solution of indiarubber, and transferred to a sheet of paper also coated with indiarubber. The two were then passed through a strong rolling press, to receive the necessary adhesion of the two surfaces. The picture was then developed with warm water in the usual way, and some of the finest carbon pictures which have ever been produced were made in this manner; the next step was the doing away with the glass plate and collodion. The pigmented gelatine was simply spread on paper, fastened to another sheet of paper with indiarubber as before, and after development gave excellent results, but, of course, reversed.

About four years after (in 1868) a Mr. Johnson patented the process as now worked. He found out that no indiarubber solution or other cement was necessary to stick the tissue to either a temporary or permanent support, provided the support used was impervious to air and water, and that, by simply applying the wet tissue to such a support and rubbing down into contact, it adhered firmly by atmospheric pressure, just as a boy's clagger (I believe you call them in this part of the world) sticks to a paving stone. The process as now worked is exceedingly simple; the tissue is exposed, squeegeed on to a piece of specially prepared paper, placed in hot water, after a few minutes the paper backing is pulled off, the picture is then developed with warm water. The print is reversed if it has been made from an ordinary negative; this is of very little consequence if the negative has been taken simply with the object of making a picture; but, if the negative is a street view or a view of a place, it would not do at all. In this case the exposed tissue is developed in a temporary support either of prepared paper or opal, and then transferred to a final paper support.

I will now run through the various processes necessary to make a finished autotype picture. To begin with, the tissue can be obtained ready-sensitised, and, for any one who intends doing a dozen prints

straight off, this is the better way to buy it. The price is the same, either sensitive or insensitive. But some of us may want a few copies now and not want to print again for a week or two. In this case, the tissue must be purchased in the insensitive state, as it gets quite insoluble after ten days or a fortnight when sensitised, and is therefore useless. Suppose we have some insensitive tissue to sensitise; it is put into a bath composed of—

Bichromate of potash	3¾ ounces.
Liquor ammoniæ	880 millimetres.
Water to	2 quarts.

Be careful to brush air bells off both back and front of the tissue, and allow it to remain in the solution for three minutes. It is then removed and squeegeed on to a piece of glass, to remove the superfluous moisture, and hung up to dry.

We now have the tissue ready for exposure in printing frame. The negative, however, must be provided with a "safe-edge" first. The safe-edge is necessary for this reason: most—in fact, nearly all—negatives have a margin of nearly clear glass round the image, and, if printed with this margin, a line of insoluble gelatine would be formed round the picture, which would in all probability peel off during development, and most likely bring a portion of the picture with it. The safe-edge is made by placing a border of black material round the negative, on the glass side. It is important that this be done on this glass side, not the film side, of the negative. Black varnish may be used to form the safe-edge, but I find a black lantern-slide binder, cut half width and gummed round, answers the purpose admirably.

The negative, provided with safe-edge, is now put into an ordinary printing frame, along with a piece of the sensitised tissue, and exposed to daylight; but, as there is no image visible during printing, we must have something to judge exposure by. The instrument used is an actinometer, of which there are three kinds in general use—Johnson's, Sawyer's, and Burton's. You will find one tint is about the correct exposure for an ordinary negative; but, after a few trials, you will have no difficulty in giving the correct exposure. The action of light, having once started, goes on to a considerable extent, so that, if a print is put out late in the day, and you see by the actinometer that it is underprinted, if put on one side and developed next morning, it will generally come out fully exposed.

We now come to development of the latent image. After exposure, the tissue has become more or less insoluble, according to the light which has found its way through the negative. The whole of the gelatine in contact with the negative has been rendered insoluble, and a good deal of the gelatine in contact with the paper, and which the light has not reached, is soluble, and it is by washing this soluble matter away that the picture is revealed from the dark mass left after the backing is removed.

We have now got to the stage in the process when it is necessary to decide whether the picture is to be reversed or in its proper position. If it makes no difference whether the print is reversed or not, we mount the tissue on a piece of single transfer paper; but, if it has to be finished the correct way, it is mounted on a temporary support, of either opal glass or a specially prepared paper support. I prefer the opal, as I find the paper support gets very much stained with the bichromate solution, and has to stay a very long time in the alum bath before the yellowness is removed, the temporary support, whether of opal glass or paper, is prepared by rubbing over it a waxing solution composed of—

Yellow wax	6 drachms.
Yellow resin	2 ,,
Turpentine	1 pint.

It is as well to wax several glasses or papers, and, when dry, put them away ready for use.

Now, having decided which support is to be used, we proceed to mount the tissue. Immerse the tissue in clean water, and also the support; the tissue will curl up slightly as it absorbs moisture, and after a few moments begin to flatten out again; when you notice this flattening out, it is the correct time to take the tissue and support out of the water, and, laying them on a flat surface, they are squeegeed into close contact; it is then put between blotting-paper under a weight, and left there for a short time, after which it is transferred to the developing tank, containing water at 110° Fahr., and, after a few minutes' soaking, the paper is peeled off the back, and the tissue washed with the water till all the soluble matter is removed; the picture is then finished, and is placed in cold water to stop any further action, then transferred to a bath composed of—

Alum	½ pound,
Water	1 gallon,

and left there till any yellowness is removed. This alum bath converts the gelatine into an insoluble parchment, and renders the pictures absolutely permanent. After leaving the alum bath the print is rinsed in water and hung up to dry, and, if one tissue was mounted on the permanent support, it is finished, and can be trimmed and mounted in the ordinary manner; but, if we began the operation by mounting on a temporary support, it must be transferred to the final support. This can be done whilst the picture is wet, but I think a beginner has a better chance of success if he allows the print to dry. A piece of final support is soaked in cold water, and then passed through a bath containing water at 120° for a few moments, and squeegeed on to the picture. They are then placed between blotting-paper under a weight, and left for a few hours, after which the mounted pictures are placed in a warm place, and, when perfectly dry, the final support is stripped from the temporary one, and brings the picture along with it in its proper position.

This process may also be used for making transparencies, lantern slides, &c., and, for making enlarged negatives from small ones, it is much better to make a carbon transparency than a gelatine one, as there is no grain in the carbon tissue.

For making transparencies, a piece of clean glass, an inch larger each way than the negative, is coated with a solution of gelatine made thus:—

Nelson's No. 1 gelatine	6 drachms.
Water	1 pint.

Soak the gelatine in cold water, then dissolve with gentle heat, and add sufficient solution of bichromate of potash to make the solution sherry colour; the coated glass is then dried in daylight, to render the coating insoluble. The tissue is mounted on this glass and developed in the usual manner, but exposure must be carried very much further than for a print—in fact, a negative which yields a good print with one tint would require five or six tints to make a satisfactory transparency.

Having now briefly described the process, I will endeavour to demonstrate it from the time the printing is done, and, although you may think the process very complicated, I think, when you see it done, you will agree with me that it is simplicity itself. T. O. Mawson.

PHOTOGRAPHY WITH THE BICHROMATE SALTS.*

The fourth lecture, delivered on Tuesday, April 28, was by Mr. J. D. Geddes, upon the subject of *Woodburytype*, Mr. W. Thomas presiding. The lecturer said the process was patented in 1864, and it was curious that it had continued up to the present time to be worked almost exactly in accordance with the details given in the patent specification; although nearly all methods of photo-mechanical printing had in some way advanced since their inception, Woodbury had had the genius necessary to enable him to place upon the market a finished and complete process, to which all the skill and research of later years had scarcely been able to add a detail. The first operation is the preparation of a film of gelatine sensitised with bichromate of potash, to which is added some substance to make it pliable and to it keep from breaking under the strain which it must afterwards undergo. The gelatine solution is coated on a collodionised glass, from which it is stripped when dry, and the film is then ready for exposure under a negative; as the film is of appreciable thickness, printing must be by direct light or the definition will be impaired. After printing, the film is cemented with indiarubber solution to a piece of thick glass, and placed in constant changes of hot water for five or six hours to remove the soluble portions, and then soaked in methylated spirit, and allowed to dry spontaneously. When dry, the film forms an absolutely incompressible relief, although feeling as soft as a piece of silk, and it is then placed between a polished and case-hardened steel plate and a sheet of hard rolled lead, the whole being subjected by means of a hydraulic press to a pressure of from 2000 to 5000 pounds per square inch, by which means a mould of the relief is formed in the lead, from which the final prints are produced. For printing, a solution of gelatine is made, of about twenty-five grains per ounce, with which a pigment is added; a pool of the mixture is poured on the mould, a sheet of paper placed upon it and the lid of the printing press brought down and pressure applied; the pigmented gelatine is thus squeezed over the entire surface, that remaining in the depressions of the relief becoming attached to the paper, and the remainder being squeezed out at the sides. In a few minutes the gelatine sets, and the paper bearing it is then removed and dried, and, after treatment with alum to harden the gelatine, the print is ready for trimming and mounting. The mould is lubricated before printing with a mixture of olive oil and petroleum, and the paper requires to be waterproofed with a varnish of shellac and borax, and afterwards rubbed over with an emulsion of gelatine and shellac to give it a tooth and prevent the image splitting off. There are two drawbacks to the process, in that the prints require to be mounted, no method of printing with a clean margin having been discovered, and it is impossible to get a pressure sufficiently even to squeeze out the ink over a large expanse of white. Mr. Geddes referred briefly to the modifications known as Woodbury-gravure and Glyptotype, and exhibited a number of slides illustrating the application of the process to lantern-slide making, specimens of sensitised film, metal moulds, printing papers, and finished prints in various colours.

Mr. Bolas passed round for examination a Stannotype mould and print made by Mr. Woodbury, and gave some historical details of the process, and after some discussion a vote of thanks was passed to Mr. Geddes, and the proceedings concluded.

On Friday, 1st instant, Mr. W. T. Wilkinson lectured on *Photo-lithography* and *Photo-zincography*, both of which processes he demonstrated. The requirements for a good photo-litho transfer were that each

* Continued from page 283.

line should be sharp and solid, and that, when damp for transferring, there must be little or no relief, while the gelatine coating must absorb sufficient moisture to cause it to adhere to the stone the first time it was pulled through the press. Double transfer carbon paper formed an ideal paper for the process, and should be sensitised in a mixture of white of ten eggs, water thirty ounces, and two ounces of a saturated solution of bichromate of potash. Exposure should be timed by an actinometer, and when printed the transfer must be inked up with a glue roller until there is a thin and even film of ink all over it; after soaking in water a short time, the ink is rubbed off the unprinted portions, and the transfer, after drying and again damping, is ready for laying on the stone. The direct method of printing on zinc was next described, and also half-tone photo-litho, and the production of collotype and screen grains. For photo-zincography the prepared zinc plate, sensitised with bichromated albumen, was printed and inked up as in litho work, and after drying the image was dusted over with finely powdered dragon's blood, which was melted by heat, and, becoming incorporated with the ink, gave a good resist. Referring to the fish-glue process, Mr. Wilkinson had found that a very bad sample of gum, dissolved in water to make a solution of the consistency of condensed milk, and mixed with albumen and sensitised with bichromate, enabled one to give a very short exposure, and could be carbonised without making the metal so brittle as in the fish-glue method. He thought that fish-glue and gum were the two best things at present; and, in his opinion, the fish-glue process, either on zinc or copper, gave a better reproduction of the fine half-tone in a photograph than any other method he knew of. Various modifications of litho and zinco work were alluded to and briefly outlined; and the audience made up in attention for the paucity of its numbers.

Friday, May 8, *Process-work Applications*, by Mr. W. T. Wilkinson. Syllabus: Photo-lithography, in line and half-tone—photo-zincography, in line and half-tone—swelled gelatine—wash-out gelatine—photogravure—dusting-on process—the various bichromates—a new application.

CAMERA CLUB CONFERENCE.*

The Conference was resumed on Tuesday evening, the Earl of Crawford, K.T., in the chair, when Mr. J. W. Gifford gave a demonstration of

The New X Ray Photography.

He said he had obtained his best results with accumulators with a ten-inch coil, and with accumulators giving ten volts four ampères were quite sufficient, and answered better than large accumulators brought down by resistance. He usually employed a hand dynamo giving ten volts, and wound with No. 12 wire. He found he could work a ten-inch spark coil, and get a very long spark from the Tesla apparatus with four two gallon size Leyden jars; but, for ordinary purposes, it was sufficient to use two of the jars, and two half-pint Grove's cells. A number of vacuum tubes were exhibited, and he showed lantern slides of several of his results. Some fluorescent screens were also shown and tested, Mr. Gifford stating that he had found potassium platino-cyanide preferable to tungstate of soda for this purpose.

The Chairman, Captain Abney, the Rev. F. C. Lambert, Mr. Stanley Kent, and others, made some remarks, and, a vote of thanks having been accorded to Mr. Gifford, Mr. Frank M. Sutcliffe read a paper on

Pictorial Photographic Portraiture.

Many years ago, he said, there were two children born to Photography, and, though they were well able to earn their own living soon after they were sent out into the world, the higher education of both was for a time sadly neglected. One of the sisters, whose name was Landscape, had, however, been taken in hand by some members of the Club, and her education was now so complete, that she was acknowledged to be fit to move in the best society; and the object of his paper was to arouse a like interest in the higher education of her backward sister, Portraiture. He did not agree with those of his brother professionals who thought it a good job that amateurs generally fail when they attempt portraiture; in fact, his opinion was that portrait photography would get no "forrarder" till amateurs mastered it. It was because the amateur could afford to disregard the conventional idea of what a good photograph is, or ought to be, that he thought salvation would come from him. Most of the conventional ideas of what a good photograph is were based on rotten foundations made of lies, such as retouching, imitative accessories, sham landscapes, trees, and plants. The amateur could trim his prints as the subject required, and could take portraits with a diffusion of focus which would ruin a country photographer's reputation in a week. Twenty years ago, Mr. Ruskin told the lecturer that he thought all photographers over-exposed and over-developed their plates, and so lost much of the subtle half-tone in the lights, upon the delicate rendering of which the poetry of portraiture depended. Simplicity, more than anything else, distinguished a pictorial from a commonplace portrait, simplicity of treatment, subject, dress, background. Next to simplicity, truth; don't dress your friend as an Italian brigand or an American cowboy, even if he has bushy black eyebrows and a fierce moustache, but take him as he is. One of the greatest secrets of successful portraiture is to let the sitter alone and let him do the posing. The use of reflectors was discouraged; but, if the light were filtered through tissue paper, the shaded side of the face would be more luminous, and the light might be concentrated or subdued where required. Everything must be subservient to the face. If it were not for the vagaries of our climate, the ideal studio would be an outdoor one, and, in diffused light or on grey days, certain effects next door to impossible in any glazed studio could be secured by those who would only look for them. Certain writers affected a very lofty tone when comparing painted with photographic portraits, and said that a painted portrait was made up of fifty different expressions of the sitter rolled into one, and that only the penetrating eye of the painter could see all this and reproduce it; but how was it that, when the painter went out of doors and painted nature, he tried his hardest to depict truthfully only one aspect of the scene? The photographer of the future would spend his youth in the study of art; the prices he would charge would make him independent of size; one sitter a day would give him employment enough, and his appointment book would be full for years in advance; but the world was not ready for him yet.

Mr. G. Storey, A.R.A., referred to an album of portraits taken by Mr. D. O. Hill some thirty or forty years ago, and now in the Club library, which he said were examples of artistic portraiture which he had never seen surpassed. Artists sometimes said that photography could not render the expression of a face, but there was a good deal of "rot" talked nowadays, and that sort of thing was part of it.

Mr. Craigie had found it impossible for any one to maintain a particular expression for more than a second or two, and he suggested that a very nice sort of composite expression was obtained by prolonging exposure, and allowing the sitter to vary his expression as he pleased.

The Chairman, as an amateur, said he recognised the importance of studying the sitter's features, but his experience was that his sitters would not give him a chance of doing so, they did not care about sitting a second time; it was unfortunate, too, that when one took a portrait of a beautiful lady, in whose good graces one wished to be, she would not speak again for a week. He moved a vote of thanks to Mr. Sutcliffe, and, the same being carried by acclamation, the Conference was adjourned.

On Wednesday evening, April 29, Captain Abney read a paper dealing with some applications of

Carbon Printing.

It was often considered, he said, that for certain puposes—such, for example, as the production of enlarged negatives—a carbon transparency was superior to one made by any other means. His experience was that, as a rule, carbon transparencies had a tendency to flatness, and the question then was, What could be done to improve them? A flat and feeble result could be much improved by changing its colour, either by means of a dye or by immersion in a solution of permanganate of potash, the latter imparting a rich brown colour, which produced a marked difference in the printing quality of the transparency. This method enabled one to reproduce a negative of satisfactory printing density from a thin and flat original, first making a thin carbon transparency and intensifying it to the necessary extent by means of permanganate solution. Spoilt celloidin films, coated with gelatino-bromide of silver, could be utilised for the production of transparencies by immersing them in a solution of bichromate, drying, printing through the back, and developing with hot water, a transparency in bromide of silver being thus obtained, which could be intensified to any degree by treatment with an amidol developer, and the image could be modified locally by brushing with hyposulphite of soda. Referring to the continuating action of light in carbon tissue, Captain Abney said that he had, many years ago, discovered that tissue which had received only one-fourth of the normal exposure would be fully printed if kept in a damp atmosphere for about fifteen hours before development; and, further, that the scale of gradation was not so great as in prints fully exposed and developed immediately. A soft negative could thus be made from a hard one by partially exposing carbon tissue, and developing after the lapse of some hours. Chromate of potash was nearly as sensitive to light as the bichromate, photographs of the spectrum taken on plates treated with the chromate showing greatest sensitiveness in the green and green-blue. In winter, carbon printing was quicker than silver printing, which was most sensitive to the extreme violet. The strength of the permanganate solution, which had been alluded to, was immaterial, the extent of intensification depending upon the time of immersion.

Mr. L. Warnerke said that carbon prints could also be intensified with gallic acid and an iron salt, which gave exceedingly fine gradation. In the event of over-intensification with permanganate, the image could be reduced by dipping in oxalic acid, which slowly dissolved the peroxide of manganese which was deposited on the film.

Captain Abney, in reply to questions, said some gelatino-bromide films were apparently insoluble, but the addition of five drops of caustic potash per pint of the water used for development rendered it easy to wash out the unaltered portions. Films treated with permanganate dried the same colour as they appeared when wet; sunlight had no bleaching effect upon films so intensified.

A vote of thanks was accorded to Captain Abney. Dr. C. S. Paterson read a paper, illustrated by a series of lantern-slides, upon the subject of *Photographing of Fish*, for the delineation of natural history specimens in a manner which should be of service to scientists. The method

* Continued from page 284.

generally adopted for making representations of such subjects was careful scale drawings by hand and engraving; the work had to be done by the eye and the hand, both of which were liable to error, it involved a great deal of time and labour, and was often entrusted to persons who were absolutely ignorant of scientific knowledge. For such drawings the subject had to be preserved in spirits, which altered the structure and destroyed the colour; and, owing to the difficulty of getting the pictures made, many rare specimens were not drawn at all. The chief advantages of photographing in this connexion lay in the facts that the scientific observer could make his own pictures at a very small outlay, and that photographs of fresh specimens could be obtained without loss of time. It was to be hoped that the Museum authorities would follow the example of Sir William Flower, and call in the aid of the photographer, so that photographs could be secured immediately upon the receipt of specimens. To obtain successful photographic representations, the operator must possess a thorough acquaintance with fish and their structure, together with a knowledge of exposure and lighting, which was only to be gained by practice; he must be able to adapt himself and his apparatus to all environments, and at a moment's notice, and he must not have a sensitive nose. The camera should be capable of long extension, and in order to facilitate measurements, an inch scale should always be included in the picture. As to the lens, the chief point to remember was that the longer the focus the less would be the distortion between the various planes; a vertical stand was very advantageous, as fish were slippery and glistening. Isochromatic plates were recommended, and a useful size was made by cutting a 12×10 in halves, so as to get a 15×5, most fish being three times longer than deep. With regard to screens, the tint must not be too dark, or colour values would be over-corrected; the colours were not those of the spectrum, but were mixed with white light, and the correction required was frequently much less than appeared to the eye to be necessary. A series of slides was exhibited showing representations of fish skeletons, obtained by Professor Röntgen's method. The exposures were made with three-inch sparks, the tube being five inches above the object; it was found that the bones did not stop the X rays, but only impeded them, and that, by over-exposing, the thicknesses of the bony strata were shown, and two or more layers of bones could be differentiated.

The Earl of Crawford, as a Trustee of the British Museum, said the question of the appointment of an official photographer had received a good deal of consideration, but the great difficulty which the Trustees had to contend with arose from the action of the Treasury. A very fine catalogue of British fishes had been issued by the Museum, but the preparation of photographs for such a large work would hardly be practicable, as a considerable proportion of the specimens were preserved before they were received. He had been agitating for some time for a Government laboratory to be attached to the Museum, but the Government did not seem inclined to spend much money on the institutions they were supposed to keep up.

Dr. Paterson said he did not wish to convey the impression that photography was not useful in the case of preserved fish; if the draughtsman could draw as well as he did from such specimens, certainly the photographer could do the work better, and quicker, and cheaper. Government laboratories were greatly needed where men trained to the particular work might be available at a moment's notice.

The Chairman (Captain Abney) remarked that he was glad to see that something really useful was being done in the way of photography by means of the X rays. He proposed a vote of thanks to Dr. Paterson, and the motion being carried, the Conference adjourned.

At the sitting on Thursday, April 30, Mr. C. H. Bothamley read a paper entitled

Some Points concerning Silver Prints.

He detailed a number of experiments undertaken for the purpose of ascertaining the manner in which a combined toning and fixing bath acts, and determining how much of the silver compound produced by the action of light remained in the print in its original condition; how much, if any, was converted into silver sulphide; how much gold was deposited, and whether any lead or lead sulphide was deposited on the image. He had adopted the plan of investigating the action of the combined bath without any gold, taking hypo and alum for one set of experiments, and hypo and lead for another set, and he had thus discovered the cause of a sort of pseudo-toning which had taken place in certain faded prints which had been brought to his notice, and upon which apparently no gold had been deposited. If an ordinary silver print were placed in acidified hypo solution, it would first be fixed, and would afterwards acquire a brownish-yellow colour which had been called "sulphurisation;" the fixing and sulphurisation did not proceed simultaneously, as was often said to be the case. Solutions of hypo and alum behaved in precisely the same way; a gelatino-chloride print removed from such a solution after four or five minutes' immersion had just the same appearance as one fixed in a slightly alkaline bath, but, if allowed to remain in the mixed solution for a rather longer time, the print was in outward appearance the same as if the image had been toned by gold. The sulphurisation was generally said to be due to nascent sulphur, but experiments proved that there was no difference whether the hypo had been acidified for some time or was freshly acidified, or whether it was freshly mixed with alum or kept before use. It appeared from the investigations of various investigators that a very long time elapsed before the separation of sulphur ceased in acid solutions of hypo or mixtures of hypo and alum; and he had treated prints in such solutions nine months old, and which were perfectly clear and showed no signs of depositing sulphur, and the results were exactly as before, the prints first fixing and then acquiring a purplish colour. This appeared to prove that the change, whatever it might be, was not due to nascent sulphur liberated from the solution; it was perfectly clear, therefore, that a mixture of alum and hypo, even after all precipitation of sulphur had ceased, would so change the colour of the print that it might be supposed to have been properly toned without any gold having been deposited upon it. Solutions of hypo with acetate or nitrate of lead were not acid, but slightly alkaline, and produced pseudo-toning of a similar kind to that caused by hypo and alum or acidified hypo. A mixture of hypo and lead nitrate deposited its sulphide of lead much more completely than hypo and lead acetate. The cause of the apparent toning in the absence of gold was said to be due to sulphurisation, a term which implied that the image was to a large extent converted into silver sulphide, but he had found that nothing like complete conversion took place, and that there was comparatively little sulphurisation. Owing to recent researches, our knowledge of the nature of the sub-salts of silver was more definite and extensive than it was a few years ago, and there seemed to be every reason for the conclusion that the dark purple substance formed by the action of acidified hypo, or hypo and alum, was not silver sulphide, but silver sub-sulphide. The main points, Mr. Bothamley said, in his fragmentary series of experiments, were that even in the absence of gold pseudo-toning was caused by the presence of alum or a lead salt or both together; that the pseudo-toning was not simultaneous with, but subsequent to, the fixing action of the hypo; and that in all probability the purple colour was due to the formation of silver sub-sulphide, a compound the stability of which helped to explain why images of that kind were much less permanent than those toned and fixed by separate operations.

The Earl of Crawford asked whether Mr. Bothamley's remarks were to be taken as arguments against the combined bath?

Mr. Bothamley said yes; but only if such a bath contained lead or alum.

Mr. Lyonel Clark asked whether the formation of sub-sulphide would tend to stop gold toning?

Mr. Bothamley said he was not yet prepared to answer the question definitely, but it was extremely likely that such would be the case.

A vote of thanks having been passed to Mr. Bothamley, the concluding paper of the Conference was read by Captain Wilson Barker, R.N., the subject being

Clouds and Photography.

After showing a series of lantern slides from photographs of every variety of clouds, he said that probably the clouds of the greatest importance as weather indicators were more difficult to photograph than any other object. Cumulus clouds were easily photographed, but the delicacy of the finer varieties of stratus, and their tendency to get swamped by the powerful effects of the blue sky, rendered it very difficult to photograph them. One of the most successful devices was the use of a black mirror, and he had got satisfactory results by interposing a very thin film of mica between the lens and the plate. Success depended chiefly on the state of the atmosphere and the degree of illumination. He used a single wide-angle lens and a Ross U. S., but the result was about the same with either, and developed with hydroquinone. Photography had aided considerably in ascertaining the height and thickness of clouds, two cameras a distance apart being connected by a telephone, and two exposures being made simultaneously on the same cloud.

A brief discussion followed the paper, and, after Captain Wilson Barker had been thanked for his paper, the Conference closed.

On Friday evening the annual dinner was held at the Café Monico. Captain W. de W. Abney, (the President), who was in the chair, replied to the toast of "Success to the Club," submitted by Mr. F. M. Sutcliffe, and claimed that during the year the organization had made substantial progress both in scientific and artistic work. It had had a feast of radiography, and on the Club walls were some ghastly productions which he would personally rather not see there. He was not sure that any save accomplished physiologists should be allowed to use the X rays, for it was rather impertinent of a man to attempt to delineate something of which he knew nothing. On the other hand, he anticipated this usefulness from the discovery, that announcements of engagements in the morning papers would one of these days conclude with an intimation that the photographs of the skeletons had been mutually exchanged. Surely it was desirable that everybody should be tested as to whether they were sound in limb before entering the married state? He noticed from a visit to the Academy that the camera was being used by painters, especially for the adequate portrayal of animated street scenes, and he believed that more and more help in that direction would be demanded of an educational club like theirs. The toast of "The Visitors," proposed by Mr. William Clarke, was acknowledged by Dr. Richardson. Other toasts were "The Press," "The Ladies," &c., &c.

NOTES FROM THE WEST OF SCOTLAND.

Perhaps there is no other thoroughfare in the kingdom that can equal Sauchiehall-street, Glasgow, for its number of photographic studios. This street, which has now become one of the leading lounges in the City

on account of its being the main thoroughfare leading west, has within recent years assumed a very gay and busy aspect, and from morn till eve is always thronged with a large crowd of fashionably attired citizens and tourists. From a photographic point of view it is unique at the present moment, for it now boasts of no less than about a dozen of the leading studios in the City, all of which are congregated within a few yards of each other. In addition to which we have the extensive business premises of Messrs. Geo. Mason & Co., and shortly The Albion Albumenising Co. are to open right in the midst of this busy crowd of photographers also. Opposition certainly would appear the life of the trade here.

Mr. Paton, the creator of the Corporation Galleries, is receiving very gratifying support in the way of the collection that will be shown at The Camphill Exhibition this summer.

Some exceedingly interesting old relics of bygone photographic days will be on view, including most likely the first photographic lens used in Glasgow about the year 1840.

Hand cameras are very much in evidence this year again, and the light during the latter portion of this month has been very favourable for shutter work.

Mr. Alexander Robb of Gourock has been doing some surprising work with his shutter *under cover*, the amount of detail he can coax out of a plate in development has astonished not a few, who thought they knew all about snap-shot work. Amidol is fast gaining in favour as a developer for short exposures.

CARDIFF EXHIBITION.

When the good burgesses of Cardiff decided to hold a big "Arts, Industrial, and Maritime" Exhibition, the Photographic Society in Cardiff who ere now have held very successful little exhibitions of their own, were asked to take the responsibility of a photographic section, to which suggestion the Society agreed.

Subsequently, however, so we gather, the general managing committee began to begrudge both the space and the money requisite, and the photographic committee appear, from first to last, to have had a very uphill and disheartening time, and finally found themselves quartered in two long widely separated corridors, with only side light, and not too much of that. Now, we know photographic Hon. Secs. are characteristically endowed with intense reserve energies, and in the present instance Mr. T. H. Faulkes seems to have accomplished great things, and with him worked the President, Mr. S. W. Allen, Mr. J. W. Jenkins, Mr. S. Williams, Mr. N. H. Kitchen, and others, so that, although brief time and small financial resources were allowed them, the two galleries possess a very creditable appearance, and a goodly number of exhibits have been got together.

Not the least difficulty which we encountered was having to report the Exhibition without a catalogue, the fronts of most of the pictures possessing no indication of title or authorship, so that the conscientious reporter had to unhang the pictures one by one to read the names on the back. This makes exhibition reviewing tedious.

It is only fair, however, to say that the omission of a catalogue was not the fault of the photographic committee. Mr. Hon. Sec. had sat up all one night to prepare the list, and had handed it in, but the first edition of the official catalogue came out minus even the merest mention of the existence of a photographic section in the whole building.

Clearly Cardiff wants educating a little. Of course, every man thinks his own particular sport, profession, or calling, the most important, and when a man is a great owner of collieries, or a great dock-owner, or shipbuilder, he cannot be expected to regard as of serious importance such a puny thing as photography; and perhaps that is how it is that the Cardiff Exhibition's strong feature is steamboats, guns, ammunition, model mines, and the like.

The first frame we were tempted to unhang to read its name on the back was *Sheep in Snow*, by Mr. W. H. Banks, which, though very nice, is hardly, we should have thought, the best in the class. Still, the Judges have seen otherwise, and given it the silver medal.

There are several nice little quarter-plate snap-shots by Mr. J. J. Jenkins, a Cardiff man, who takes the medal in Lantern-slide Class.

Fast Falls the Eventide, by Mr. Howard Esler, we remember to have seen before, and, whilst we admire it for some qualities, we feel sorry that its value is seriously marred by a figure which disputes chief attention with the boat stranded on the soft mud.

Mr. Charles Moss and Mr. Charles Job are both represented by several works shown last year in London, the former receiving a bronze medal for what we do not hesitate to call the least worthy of the things he shows. Mr. Moss can and does do some very capital work, and he has better pictures here than the winding road and dark masses of bushes and trees which the Judges have thought fit to award.

Mr. C. Job has a sheep picture, which, although high up, we climbed up to, and ascertained its title to be *Linfield, Sussex*, very pretty, bright, and well chosen.

Quite unconventional is W. Thomas's narrow upright print of a very grey, misty character, a sunset over some snow-covered ground. We cannot help feeling that this is a bit cut out of a larger negative, and, whilst trimming down is an excellent practice, it should never make itself felt.

In the Portrait Class, which is a large one, the silver medal is withheld, and two bronze medals given to Mr. Percy Lankester and Mr. W. J. Jenkins respectively, and a certificate to Mr. Smedley Aston.

The sort of education we have intimated as being desirable in Cardiff will not, we fear, be accomplished by the painfully commercial showcase style of some exhibits in the Portrait Class. Large stippled-up heads, sumptuous grey and gold enamelled frames, upholstered in crimson plush, and a similarly decorative (?) advertisement, containing showy portraits of fair ladies, the former having a great number of other frames of large silver prints, figures classically draped, and some —— well, the gallery was deserted, and last year's Salon has prepared us for a good deal.

Mr. Byrne of Richmond, has a large frame containing some thirty or forty exquisite child portraits, any one of which, if mounted alone, would be quite enjoyable.

Close at hand are some of Mr. Hollyer's finest works, which he has lent, and we hope Cardiff people will study these, and take their lesson to heart.

Admirably executed, and most ingeniously contrived, is the charming damsel who sails on the horn of the crescent moon, and for this and other works Mr. Samuel Allen, the President, is responsible, and is justly proud of.

Mr. Percy Lankester receives the silver medal in the *Genre* Class, and Mr. F. M. Sutcliffe, the bronze. Messrs. J. Chaffin & Sons, of Taunton, show a large number of silver prints which have an odd old-fashioned look, and here, too, are J. Coath's well-carried-out series of children, dressed in fancy costumes, playing a part, such as courting, reproving, &c.

H. L. Isenberg shows three bird studies in brown carbon, which, both in idea and conception might be very noticeable, but for Mr. Gambier Bolton's work which has spoilt one's taste for anything but the very finest animal studies.

In the Champion Class are a very fine lot of things. Mr. E. R. Ashton's *In Nubia* has, like all his Oriental studies, a peculiar and distinctive quality.

Here, too, are two tiny gems of landscape by W. B. Post; S. B. Bolas & Co's *Winchester Cathedral*; and Mr. Steiglitz'a *Scurrying home*, seen last year at Pall Mall, has the honour of carrying away the gold medal.

Mr. Robert Terras's well-known *Ghost Story* is here, with several more of the same class, though hardly of the same merit, entitled *Holiday Morning*, *Grannie's Counsel*, *News of War*.

Messrs. Chaffin & Son have a *Grief* (No. 210), which is, in our opinion, far above anything else they show. It is a girl and dead bird, posed somewhat statuesquely against a quite dark background, and only fails being very successful for want of a little discretion in tinting down the masses of white drapery.

Mr. Bedwhar's *At the Fountain* will always be welcome, and Edgar G. Lee's *Castle Garth*, also *At the Smithy*, are both excellent.

Mr. W. H. Kitchen, an active member of the Cardiff Society, shows three good enlargements—*A Haymaker*, *Carnarvon Castle*, and *Village Smithy*.

Mr. Archibald Goldie has a clever little picture of a woman suckling a baby, which was medalled at Amsterdam. The subject, although one most difficult to treat, has been done cleverly, with good taste, and even with a poetical touch about it.

Architecture seems a large class, owing, no doubt, to the large size of most of the frames and the number sent in by each of several exhibitors.

W. D. Dighton, a local photographer, has a fine carbon enlargement of an interior of Cardiff Castle, and a number of silver prints of unequal merit.

S. B. Bolas & Co. send a big lot of large interiors, for one of which they receive the silver medal.

A remarkably fine photogravure is duly distinguished by a bronze medal. This is by Mr. Harold Baker; and an extra bronze medal goes to Mr. E. R. Ashton for an oriental subject.

Mr. T. H. Faulks is a very prolific worker, and occupies a great amount of space in the Enlargements Class with some excellent work. The silver medal for enlargements goes to a Cardiff man, Mr. W. H. Kitchen, for his *Anticipation*, a technically good enlargement from a football snap-shot, and the same exhibitor has some good marine enlargements. Bronze medal is awarded to S. H. Beale, of Banbury, and a certificate for *Alteryn*, by T. Mitchell.

The Hand-camera Class is very small, there being only three or four entries, and a bronze medal falls to the lot of Mr. W. Thomas, the silver medal being withheld.

The Lantern-slide Class, too, is not large, and the medal is given to Mr. J. J. Jenkins (Cardiff).

Some excellent X ray results are shown by S. W. Allen, and some photographs of geological formations by W. Norrie, both these gentlemen receiving special bronze medals.

Many fine examples are sent, "not for competition," by Messrs. F. Hollyer, Horsley Hinton, Ralph Robinson, West & Son, and others. Jesse Williams & Co., of Cardiff, show a large assortment of chemicals, apparatus, and sundries.

List of Awards.

Class A (Landscape and Seascape).—Silver medal, *Sheep in Snow* (No. 7), W. H. Banks; bronze, *Homeward Bound* (No. 32), Charles Moss; certificate, *Sunlight and Shadow* (No. 70), Charles Job.

Class B (Portraiture).—Silver medal, withheld; bronze, portrait (No. 85), W. J. Jenkins; extra bronze, *Gladys* (No. 101), P. S. Lancaster; certificate, study of a head (No. 103), W. Smedley Aston.

Class C (*Genre*).—Silver medal, *Natives of these Isles* (No. 149), F. M. Sutcliffe; bronze, *In Nubia* (No. 190), E. R. Ashton; extra bronze, Greek study (No. 143), F. L. Lancaster.

Class E. (Enlargements).—Silver medal, *Anticipation* (No. 348), W. H. Kitchin; bronze, *A Classic Corner by Severn's Side* (No. 330), S. H. Beale; certificate, *Alteryn, Newport* (No. 335), Colonel P. Mitchell.

Class D (Architecture).—Silver (No. 318), S. B. Bolas & Co.; bronze, *A Portico, Cairo* (No. 270), E. R. Ashton; extra bronze, *Warwick Castle*, photogravure (No. 277), Harold Baker.

Class F (Hand Camera, set of six).—Silver medal, withheld; bronze, W. H. Thomas.

Class G (Lantern Slides).—Silver medal, J. J. Jenkins; Bronze, C. S. Baynton; certificate, W. Pugh.

Class H (Champion).—Gold medal and shield, *Scurrying Home*, A. Steiglitz.

BIRMINGHAM PHOTOGRAPHIC EXHIBITION.

The increase in the number of outside exhibitors, the inclusion of a number of survey pictures of the county of Warwick, and the rearrangement of the screens bearing the pictures, makes this—the eleventh—the most imposing show the Birmingham Society has yet held.

As in previous years, we are struck by the large number of classes the works are split into, too many medals being offered; and, again, we earnestly suggest that the local Society might vastly increase the artistic value of their rewards by reducing their number. In the members' classes there are no longer the few workers standing head and shoulders above their fellows, but there has been a general levelling up, and, speaking generally, the competitions are keen, and must have presented considerable difficulty to the Judges, Messrs. Lambert, Gale, and Burt. Mr. T. C. Hepworth was to have acted as the third adjudicator; but, telegraphing his inability to attend, the well-known artist, Colonel Burt, was called in at the eleventh hour. The effects of the Salon with regard to frames and other matters would seem to be passing away, while the tendency to supplant the colder tones of platinotype by various colours, more or less pronounced, is another feature that forces itself upon one.

In Class I. (Open Landscape) the silver medal is awarded to W. T. Greatbach for a sunset effect, which is particularly noteworthy for its uniform excellence. It represents low-lying woods on the far side of a pool with fine clouds, which are reflected in the still water. We should say this is a picture produced entirely at one exposure, so well does the lighting harmonise over the whole work. So strong was this class that the Judges awarded two extra bronze medals, one to a striking subject in which some Scotch firs on the crest of a hill stand in bold relief against a distant landscape, by F. Bolton. The second bronze goes to A. J. Jeffreys for a winter river scene, somewhat "tender" compared to surrounding works, but well worth the award. *The Mill on the Avon*, by C. S. Baynton, takes a certificate, and other notable works are shown by J. P. Croft, No. 9, *Departing Day*, by Greatbach, *Auld Kirk Yard*, of John Stuart; while No. 66, *A Dutch Waterway*, by W. J. Warren, we hardly consider a success.

Class II. (Seascapes, Open).—As might be reasonably expected at so inland a town, the exhibit in this class is small; but a local competitor, Mr. Smedley Aston, takes first with *Seawards*, a work of very considerable artistic worth, but perhaps too great a leaning to the fuzzy. Four marine studies in platinum, showing excellent work, by C. F. Inston, take the bronze, while No. 78, *Sunset across the Channel*, seems to be about the best of those that the Judges have passed over. The class shows good work though numerically weak.

Class III. (Open, *Genre* and Figured Studies) is a good strong class, and here again the Judges have awarded two extra bronze medals. The silver medal is taken by O. W. Huntingdon for *In an Attic*, a gracefully posed girl working at a spinning wheel, although the thought at once occurs that we should hardly expect a lady so dressed to occupy an attic. No. 122, a portrait study, secures a bronze medal; this is, we think, under a green glass, which gives a ghastly and unnatural effect to the subject. *After the Day's Work is Done*, by Greatbach, is a new rendering of a familiar subject, good in arrangement, but a tendency to heaviness; *Domino* and *Dora*, two fine studies of children, by Ayton, three figure studies at Cairo, by Ashton, *Holiday Time*, by Fred Coop, and *Pierrot Reminiscent*, by I. Cruwys Richards, are all worthy of highest commendation.

Class IV. (Open, Enlargements).—Silver medal, S. E. Wall, for a fine work on tinted paper; a seascape of stormy character take the first award, backed up by an Alpine scene by W. C. Crofts which takes the bronze. *Cloisters at Gloucester*, by C. S. Baynton, is a good work, also the *Banqueting Hall at Haddon*, by Croft; *Nearly Home*, a seascape by J. B. Johnson. No. 183 *Smoke-circled Sky*, by McNab, astonished the Birmingham public accustomed as they are to smoke. *A Sussex Lane* would seem to be constructed of the same material.

Class V. (Open, Lantern Slides).—A set of architectural subjects by W. H. Bagnall worthily take first place; while another architectural set by E. R. Bull take the second award; H. O. Isaac takes a certificate. The following classes were open to members of the Society only.

Class VI. (Clouds) is usually a very strong and effective class at Birmingham and we were, therefore, surprised at the smallness of the entries; the medal is withheld and the award of a certificate made to P. T. Deakin, although we think there is a little too much landscape for a cloud class, No. 360, by Longmore, being rather more to our fancy.

Class VII. (River Scenery) is scarcely up to the form we find at Birmingham. *An Autumn Morning*, by W. S. Aston, takes the silver medal, although we cannot quite approve of the Judges' choice. *Dawn*, by C. S. Baynton, takes a certificate, and is in a similar key. No. 374, by Greatbach, is a bright summery bit on the Stow.

Class VIII.—Home Portraiture is more than usually successful as a class. No. 410, a fine head, good in pose and lighting, by Smedley Aston, wins; the same exhibitor, also takes a certificate for No. 412; while T. Taylor and B. Moore also take certificates. Nos. 402 and 403, by I. Cruwys Richards, although not rewarded by the Judges, are excellent, while the work of W. P. W. Browne, Whitworth Wallis, and T. Taylor are also noteworthy.

Class IX. (Architecture, Exterior).—W. P. Greatbach adds to his laurels by the aid of the *West Door, Chester Cathedral*, and C. J. Fowler takes an award with *Compton Wyniates; Buildwas*, by Baynton, and an old gateway at Cambridge, by Underwood, are good.

Class X. (Interiors) is also taken by Greatbach with the *Cloisters, Chester*, this is followed by much other good work by Baynton, Deakin, and Moore.

Class XI. (Small Landscape) *After the Rain*, by J. P. Croft, a river bit of which more might be made, and *Marshland*, by P. T. Deakin, for first.

Class XII.—Instantaneous and Hand-camera Work is a weak class, the best being by Baynton, *Off Scarborough*, and a street scene on Lifeboat Saturday. The Flower Class is taken by W. Smedley Aston for a good set of three.

Class XIV. (Lantern Slides). The Judges gave W. Bateman and W. P. W. Browne as equal, C. J. Fowler and Baynton taking certificates. The Novices' Class is headed by Bateman with three fine enlargements in carbon of architectural subjects. C. H. Barnsley coming next, with R. Hemming third. Dr. Hall-Edwards takes a certificate for radiographs in Class XVI., and the three Warwickshire Survey Classes are won by Baynton, Greatbach, and Baynton, being followed by F. Lewis and Underwood. In addition to the competition work, there are a large number of prints of the Warwickshire photographic survey and shortly to be presented to the town. The Exhibition closes on the 9th, Lantern shows being given in the evening by Messrs. Wallis, Cossins, Ward, Baker, and Pickard.

The Inquirer.

*** *In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* Journal *useful and instructive.*

Toning Difficulty.—In the Answers to Correspondents column, last week, in reply to a query on the subject of toning albumen paper, it is suggested, if ready-sensitised paper is used, to try another sample. I should like to ask you, or any of your readers who may be able to give the information, whether there is *any* sample of ready-sensitised albumen paper that will tone as readily when it is a few months—or even weeks—old as when new. I am not asking for the name of any particular brand in order to give it a free advertisement, but simply for a statement of the fact, since, in my experience with, I think, all the best brands in the market for many years past, I have invariably found, however well preserved and whatever expedients were resorted to for that purpose, that the paper gradually becomes slower in toning, and loses its original power of taking a really good tone. Gelatino-chloride differs very greatly in this respect, and I have had prints on more than one of the popular makes that, after lying untoned for months without any special care, have toned as quickly and as well as those newly made upon fresh paper. I would suggest that perhaps J. T. P.'s paper has been a long time either on his or the dealer's hands.—Red-gauntlet.

HALF-TONE SCREEN.—"I have purchased a half-tone cross-line screen, quarter-plate size, but the glass is much larger than that, and will fit neither quarter nor half-plate camera. I can, however, use a carrier, or adapter, with the latter size of camera, but what puzzles me is how to get the screen at the proper distance from the sensitive plate. I shall use dry plates, but, even if I place screen and plate in contact, the two will not go together into the slide, and, if I fix the screen outside and in front of the slide, the distance between it and the plate will be considerably over a quarter of an inch, and I am told it should not be more than three-sixteenths. How is it done?"—H. HARPER. You will have to provide a special slide or screen-holder, though a makeshift, described in another column, may help you.

BICHROMATED ALBUMEN PAPER.—CLONMEL says: "Mention was made by 'Dogberry,' a few weeks back, of albumen paper sensitised with bichromate of potash. I have tried this, floating the back of the paper on the solution, as he states, for two minutes, but the only result I can get is that the whole of the albumen is washed away after exposure, leaving no image whatever except that produced by the bichromate in the body of the paper. The sensitising solution, in fact, does not appear to penetrate to the albumen at all. Next I tried floating the other side, but sure, the albumen is removed before exposure. I did manage, by floating the back until the paper came limp and then just turning it over for a second, to wet the albumen to keep some of that on the surface, but it was only a thin, dull coating, and then, after exposure, never a bit of it would wash away, but what there was stopped there. I would be glad if 'Mr. Dogberry' could tell me where I am wrong at all."

DIFFRACTION GRATINGS.—J. HARRISON asks whether Lord Rayleigh's paper on this subject, read before the Camera Club Conference will be printed *in extenso*. He goes on to say: "From the abstract published in last week's issue, I do not gather whether the author gave working details of the different processes he mentioned, but it occurs to me that the successful employment of collodio-chloride upon glass for such fine work as gratings, with 10,000 lines to the inch, or one thousand for that matter, does not seem possible under ordinary circumstances. Setting altogether on one side the question of 'structure,' which is always very prominent in collodio-chloride, the crystallisation of the soluble salts in the emulsion—the direct printing method is referred to—would, one would imagine, utterly destroy all definition. Even with gelatino-chloride applied to glass, I should think the danger would be present; but, in the case of collodion, I do not see how it could be avoided. Can you, or any who have had experience in this direction, give me any information? also where can I find an albumen formula suitable for the purpose?' The paper will, no doubt, be printed in due course in the *Camera Club Journal*; when it appears, we shall probably have something to say on the subject.

DEFECTIVE COLLODIO-CHLORIDE. — J. P. writes: "I have a quantity of collodio-chloride emulsion made by myself from a formula I found in a back volume of the JOURNAL, and, although when newly made it printed quickly and vigorously, and toned well and easily, it gave a very thick and uneven film, running in ridges and even lumps, the coating having something the appearance of a newly ploughed field on a small scale. When immersed in water previous to toning, the paper curled up into a tight roll that was most difficult to unfold, and, when the emulsion was applied to glass, it was impossible to wash it without causing it to leave the plate altogether; but this was last autumn. A short time back, on turning out the emulsion for use, I found it had become solid, as if the ether and alcohol had all evaporated; but this I know not to be the case, as, independently of the fact that it occupies the same bulk as previously, the stopper has been tied down, so that evaporation is impossible. Can you suggest what is wrong, and tell me if I can restore the emulsion to a useful condition?" Without further data to go upon, we can only suggest, from the description of the behaviour of the emulsion when new, that an unsuitable pyroxyline has been used. The solidification is a very common occurrence when excess of citric acid is employed and more especially in the presence of calcium salts. We fear there is no way of restoring the emulsion, though perhaps some of our readers may be able to give advice.

CARBON PRINTING (To J. C.).—The reply of W. Benington to this query last week is, I venture to think, misleading, to say the very least. That "carbon requires a rather particularly plucky negative" is indeed news to me, and will be, I fancy, to most carbon workers of any experience. I am not prepared to say whether or not it is correct to say that it "will stand a greater amount of contrast than any other process," but it is a fact that it may be adapted to suit very dense, hard negatives, just as it may, by special treatment, be rendered suitable for extremely thin, soft negatives, such as would, with difficulty, be got to yield respectable prints by any modification of the albumen process. It is, I imagine, W. Benington who has failed to "study his text-book instructions," if he is really unaware that, by varying the strength of the bichromate bath used in sensitising the tissue, its character may be so modified that it is equally applicable to very dense or very thin negatives; and, years ago, I have often availed myself of this fact to obtain prints from negatives that were utterly useless with albumen. There is scarcely any printing method that is not, to a greater or less extent, capable of modification in this manner; albumen paper, gelatino-chloride, and collodio-chloride, can all be prepared to suit varying characters in the negative, but, in my experience, none possess greater or as great latitude, in this direction, as carbon, and I am surprised to see any one lay down the dictum that it *requires* a special character of negative, and more particularly a plucky one. If J. C. will reduce the strength of his sensitising bath from five per cent. (which I dare say he is using) to two and a half, or even one and a half, he will find he will get more brilliant prints from comparatively thin negatives. I have used a bath as weak as five grains of bichromate to the ounce, and, though the tissue is slower in printing, it gives results from thin negatives that would compare, at any rate, with gelatino-chloride; I have had no recent experience with modern collodio-chloride, so am unable to make any comparison with that.—SYNTAX.

Our Editorial Table.

THE "SENSIBLE" EXPOSURE NOTE-BOOK.

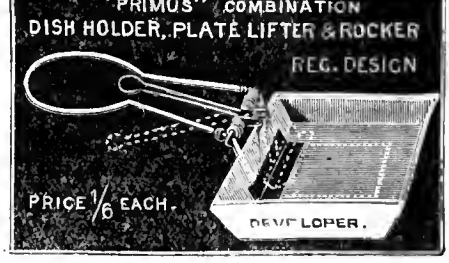
Archer & Sons, 43-49, Lord-street, Liverpool.

A NEAT little book, small enough to be placed in the waistcoat pocket, and giving on each page spaces for recording particulars of subject, slide, date, hour, light, lens, stop, exposure, plate, &c. It should be appreciated by amateurs.

THE "PRIMUS" COMBINED DISH-HOLDER, PLATE-LIFTER, AND ROCKER.

W. Butcher & Son, Blackheath.

THE illustration shows a little adjunct to the amateur's developing



outfit. It fulfils its three offices in an effective manner, and will, doubtless, be welcomed by those to whom digital cleanliness in development is regarded as an essential.

THE IMPERIAL P.O.P.

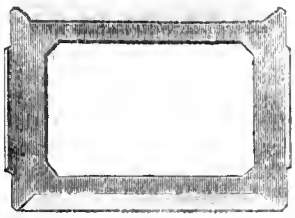
The Imperial Dry Plate Company, Cricklewood.

THE latest introduction of the Imperial Company is a printing-out paper which, judging by the specimen prints upon it that are before us, as well as some that we ourselves have taken, has been prepared with an eye to the production of the highest class of results a surface of this nature is capable of giving. The sulphocyanide toning bath is recommended. Nothing better in the way of gelatine prints could be desired than those yielded by the Imperial P.O.P. The tones are good, rich, and pleasing, and the paper therefore stands every chance of achieving success.

The Edwards' Developing Holder for Films.

B. J. Edwards & Co., The Grove, Hackney.

To the user of cut films, a neat and effective holder for the films as they pass through the operations of development, fixing, washing, and drying, is almost a necessity. It is well met in the Edwards'



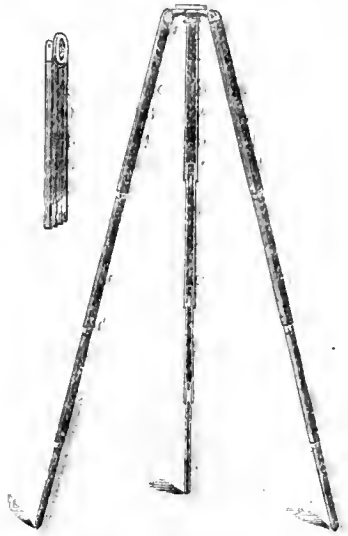
holder. This is formed of thin metal with the edges turned over, and when the film is placed in position, development and subsequent operations may be proceeded with without disturbing the film. The holders are not damaged by the solutions, and, besides being useful, are decidedly cheap.

The Edwards' Camera Stand.

B. J. Edwards & Co., The Grove, Hackney.

The Edwards' Camera Stand is the practical and successful outcome of the attempt to combine in an instrument of this class the qualities of rigidity; rapidity and facility in fixing for use; lightness and compactness when folded. These ends have all been attained, the consequence being that in actual out-door work the handling of the stand cannot fail to be satisfactory.

Metal is employed in the construction of the stand; and the arrangement of the parts ensures the complete absence of vibration. The legs are made in U-shaped sections which fold one within the other. Instead of being fitted with the usual spike at the end of



the legs, they are furnished with rubber feet, which are very durable, and prevent slipping. Besides sheet metal, aluminium, at about double the cost, is employed for the sections, the joints of which are protected by tempered brass "shoes," which impart rigidity and strength.

The stand is made in various patterns. The larger illustration shows pattern C, with adjustable folding head, open and closed, the head being a permanent part of the stand. The second illustration shows the manner in which the stands are folded up. The camera screw having been slackened, the legs are brought side by side, and unlocked by pressing on the springs as shown; then, in pattern C, the three legs are folded section within section simultaneously, the head turned down and a compact parcel is formed like the illustration on the left hand of the first figure. This parcel measures 18 inches long by $2\frac{5}{8}$ inches wide, and $\frac{3}{4}$ inch thick.

We may add that, from practical trial, we could not wish to work with a more rigid, light, and generally serviceable camera stand.

The Canesi Wrapper.

L. Canesi & Co., 366, Old-street, E.C.

Photographers who are accustomed to send photographs through the post will find in the Canesi wrapper a good and simple means of packing the pictures for transit. The wrapper is of the usual form with projecting tabs, and the whole thing, when folded over and stuck down, makes both a convenient and protective method of sending photographs by post.

Professor Röntgen's "X" Rays.

By August Dittmar. London: Whittaker & Co., Paternoster-square.

An illustrated pamphlet of thirty-two pages, giving a brief account of Röntgen's experiments and the method by which radiography is accomplished. The introductory part of the pamphlet is devoted to a description of the nature and phenomena of electricity, and the work is calculated to be useful to those undertaking the new photography, and desirous of acquiring the necessary elementary electrical knowledge.

A Matt-grain Silver Chloride Paper.

C. A. Rudowsky, 3, Guildhall-chambers, E.C.

The leading characteristics of this collodio-chloride paper are that, besides having a matt surface, the paper itself is grained. It is made in four tints—white, sky-blue, sea-green, and brown, and thus a variety of pleasing effects may be obtained with it. Photographers will probably welcome the paper on this account. It is certainly an excellent and artistic printing surface.

News and Notes.

Mr. George W. Tottem, F.R.P.S., formerly Secretary of the European Blair Camera Company, has rejoined the staff of the Eastman Photographic Materials Company.

A copiously illustrated article dealing with the studies of Sir Edward Burne-Jones will form one of the chief features of the mid-May number of the *Studio*. The supplement accompanying this part will be an original etching by E. W. Charlton, A.R.E.

Royal Photographic Society.—Ordinary Meeting, Tuesday, May 12, at 12, Hanover-square at 8 p.m. *Dry Plates for Röntgen-ray Photography*, by H. Snowden Ward; *Notes on the Pyro-developed Image*, by Alfred Watkins; *A New Stripping Film for Negative Work*, by J. B. B. Wellington.

Mr. Lambert Matthews informs us that that the Scientific Hand Camera Company have entrusted him with the charge of their London office at 97, Queen Victoria-street, City. He will be much pleased to explain the special merits of the Scientific Camera to any who may favour him with a call at that address.

The Photographic Club.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, May 13. The evening is set apart for an Open Night, and members are requested to bring objects of interest to the meeting. Visitors are welcome.

A Photographer's Bankruptcy.—*Re* Abraham Booth (Nottingham).—Questioned by the Official Receiver, debtor said he was a photographer's assistant, living in lodgings at 2, Palin-street, Hyson Green. His liabilities amounted to 88*l.* 6*s.* 3*d.*, and he had no assets or property except 13*l.*, which he had deposited with his solicitor. He had been a photographer on his own account, and had commenced buiness about twenty years since at Belper. He was brought up to the business of a draper. From Belper he went to various places, and eventually he had a business on Mansfield-road, Nottingham. He went there about 1890, and remained there three years. Whilst he was in those premises, he carried on business with plant and furniture belonging to Mr. Wm. Jackson, his landlord. Afterwards he moved to 2, Palin-street. Miss Gertrude Fletcher joined him in the business before he went to Mansfield-road. She was the tenant of the house at Palin-street. His wife obtained a decree in the Divorce Court on May 7, 1895, and he was ordered to pay the costs of the action. The costs were taxed at 61*l.*, but he had paid none of them. He gave Miss Fletcher a bill of sale on his plant, furniture, and stock on May 11, to secure to her the sum of 107*l.* His indebtedness to Miss Fletcher was for 97*l.* She gave him 10*l.* at the time the bill of sale was made.—The Official Receiver: What became of the 10*l.*?—Debtor: I'm afraid I spent it rather recklessly. I spent it on brandies and sodas and cigars. Continuing, debtor said Miss Fletcher had had two legacies, one coming from an aunt in Derbyshire. After the date of the bill of sale he became Miss Fletcher's assistant in the photography business. She paid him 1*l.* a week and kept him. Miss Fletcher was a practical photographer. He had not been in business on his own account within three years of filing his petition. He considered that since 1892 Miss Fletcher was the sole owner of the business, because of the money he owed her. He had been aware of his insolvency since 1889.—The examination was declared closed.

ARTS AND CRAFTS EXHIBITION AT BODMIN.—The Annual Exhibition of the above, in connexion with the Bodmin Section of the Girls' Friendly Society, was held in the Public Rooms, Bodmin, on April 28 and 29, 1896. It consisted of oil and water-colour paintings, carvings, art needlework, and other kinds of decorative work, also a class for photographs. This class was rather weak, but some of the photographs afforded interest. There was only one prize given, which went to Miss Tremain for a set, viz., *Where are you going to, my pretty maid?*, but in this exhibit natural scenery is given, giving good effect; the figures are very small, but well posed. Some lessons were to be learned by the studious in photography in reviewing the oil and water colours, whilst others suggested the thought and wish "never to do likewise." Refreshments and good entertainment served to keep the reviewing from being monotonous, and led many to wish the next annual would come soon.

THE NEW ASTRO-PHOTOGRAPHY.—Mr. D. Packer writes to the *English Mechanic:* "The latest feature in this new research is an important and very surprising one. It has been found that, if a sheet of metal, or even glass, is exposed for a few minutes to the focussed image of the sun, immediately transferred to the dark room, and placed in contact with a photographic plate or paper for several hours, on development an image of the solar corona makes its appearance. To obtain a good result, it is necessary to treat the metallic or glass plate as if it had received a charge of electricity. Nothing metallic should be allowed to come in contact with it, and it should be taken out of its frame by some insulating tool. This new discovery goes far to prove that the nature of the newly discovered radiance is electrical. It also affords a very important confirmation of the direct method of exposure, for it is evident that, if both methods show the same result, the phenomenon must be real, and not due to any leakage of light or a mere effect of contact. M. Niépce long ago discovered this remarkable property in sunlight (*Comptes Rendus*, vols. for 1857-58), many papers), and he even bottled up this 'invisible phosphorescence,' as he calls it, in tubes saturated with a solution of tartaric acid or a salt of uranium, which, after exposure to light, retained their property of affecting photographic paper for months after, thus wonderfully anticipating Professor Salvioni's cryptoscope."

HOTELS IN NORWAY.—Mr. F. A. Bridge writes: "The hotel proprietors of Norway are becoming keenly alive to the advantages of having dark rooms, and at several of the places where Mr. Bridgman and I stayed on the occasion of our last visit we could (had our folding tents not made us independent of it) have had very good accommodation for changing our plates. In some instances, however, these so-called dark rooms were only a delusion and a snare. The hotels, except in the cities, are built almost entirely of wood, and it is never wise to begin changing plates until you have been in the dark room a short time. These cupboards seem all right at first, but after a little while there is no difficulty in seeing the rubbish left behind by the previous occupant, or, for the matter of that, reading a newspaper quite comfortably. Notwithstanding that last season was very short, and not considered a very prosperous one in some parts of Norway, things appear to be flourishing in Bergen, and in their preparations for the forthcoming season the hotel proprietors have not forgotten the amateur photographer. Only a few days ago I received a letter from Mr. Smeby (proprietor of Smeby's well-known hotel), in which he tells me he has also purchased the Hotel Bergen, on the opposite side of the street, and, among the attractions of the new hotel, he mentions a large dining-room, which will hold nearly 100 people, 100 beds, a good smoking-room, a fine garden, 'which I think everybody will like,' and last, though not least, a nice dark room for photographers to use. Intending visitors to Bergen should 'make a note' of these combined advantages."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

May.	Name of Society.	Subject
11.....	North Middlesex	*Perspective, in Connexion with Photography.* W. E. Debenham.
11.....	Oxford Camera Club	*Platinotype.* T. H. Stringer.
11.....	Richmond	Annual General Meeting.
12.....	Ashton-under-Lyne.....	Excursion: Bowdon, for Dunham Hall and Park. Leader, S. Sharp.
12.....	Hackney	*A Cycling Tour with a Camera.* E. T. Coombes.
12.....	Royal Photographic Society ...	*Dry Plates for Röntgen-ray Photography.* H. Snowden Ward.—*Notes on the Pyro-developed Image.* Alfred Watkins.—*A New Stripping Film for Negative Work.* J. B. B. Wellington.
13.....	Croydon Camera Club	Photographic Chat.
13...	Photographic Club	Open Night.

14	London and Provincial	*Photo-micrography.* S. Ashby.
16	Aintree and District	Excursion: Knowsley Hall and Park.
16.....	Ashton-under-Lyne.....	Excursion: Hebden Bridge, for Hardcastle Craggs. Leader, Walter Leigh.
16.....	Birmingham Photo. Society ...	Excursion: Warwick and Guy's Cliff.
16.....	Borough Polytechnic.....	Excursion: Chingford.
16.....	Croydon Camera Club	Excursion: Half a Day with Mr. A. R. Dresser. Leader, The President.
16.....	Hackney	Excursion: Enfield Town. Leader, J. J. Westcott.
16.....	Leytonstone	Excursion: Dorking. Leader, W. J Battell.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

April 30,—Mr. E. H. Bayston in the chair.

Mr. T. E. FRESHWATER exhibited some shadowgraphs of a young pigeon and a dove.

HALATION.

The HON. SECRETARY said that Mr. Wiss had expressed his opinion at a previous meeting that halation was largely due to radiation in the camera, and had since been good enough to get a piece of ruby-coloured glass, coated with emulsion, which he had asked him (the Hon. Secretary) to expose with another plate, coated with the same emulsion, but on ordinary glass. This he had done, but the ruby glass was so intense that it was practically impossible to judge if any effect as suggested had taken place, but he was going to strip the film and make a comparative examination of the two negatives.

Mr. TEAPE, after an examination by gaslight, pronounced his opinion that there was no halation in the negative on the ruby glass.

The SECRETARY, referring to some surprise that had been expressed at his recommending a developer weak in pyro, passed round a negative developed with three-quarters of a grain of pyro per ounce, and which he thought would have been better with less.

Sample sheets of Hedliczka's new Vindobona Rembrandt celloidin paper were distributed, and, in a short discussion on the subject, the Secretary said he had tried some collodio-chloride papers, but did not like them much, as they had a tendency to yield "flat" prints.

Mr. EVANS then gave a display of some of his lantern slides of Lincoln Cathedral. Referring to the idea that he had come there to show them how to overcome halation in work of this kind, he was afraid there was some mistake. His practice was to shirk the impossible, and avoid too difficult subjects. He used films wherever possible, and advised them to do likewise. By these means he said he had got a good many successful accidents together, and thus got the credit of conquering halation. He used pyro ammonia (from half to three-quarters of a grain per ounce), and developed slowly, giving a full exposure. His negatives were all done on whole-plate size, and were the result of eight and a half days' work, all the development being done at Lincoln, as he wished to make sure of his bag before leaving. Pyro ammonia was also used for the slides, and they were very fully developed, if necessary being reduced subsequently. During the exhibition of the slides he gave a running history of the building and the restorations that had been made, distinguishing the Norman from the Early English additions. Every subject, he explained, had its own special hour of lighting, and required careful judgment to dodge the effect of the rays of light from the many windows. To show more plainly the detail in some of the carving and sculptures, he threw on the screen enlarged portions from the same negatives which were much admired, as were the whole series. He was opinion that an unbacked film would work quite as well as a backed plate, unless a very special subject, and he thought that, if films could be backed, they would be almost perfect. Very little backing was necessary at Lincoln, there being a good deal of colour in the windows, but he agreed that there were many places where it was beneficial.

The HON. SECRETARY had found a deal of difference in the colour of the stonework, and instanced a place where it was glaring white and very difficult to render.

Mr. EVANS agreed. He preferred to have a lot of stained glass in a cathedral, as it gave a chance of long exposure, and was infinitely better than colourless windows.

Mr. TEAPE'S experience with films was not great, which probably accounted for his belief that films were not so subject to halation as glass plates. He commended Mr. Evans's habit of avoiding severe tests.

PHOTOGRAPHIC CLUB.

APRIL 29,—Mr. J. E. Hodd in the chair.

Mr. Frank Haes showed one of Stone's piston pumps, which he used as an alternative, and preferably, to a pneumatic ball, for releasing his instantaneous shutter.

Mr. ISENTHAL then read his paper, entitled

A SYNOPSIS OF THE NEW PHOTOGRAPHY,

which he illustrated with a selection of lantern slides, showing the very "up-to-datest" results obtained by English and other workers. After the paper, the lecturer gave a practical demonstration of the method. He also illustrated the use of the cryptoscope—a fluorescent screen by which the action of the X rays is made visible to the human eye. The apparatus, which was made by Hurst & Co., of 66, Fenchurch-street, consisted of an intensity coil capable of making a six-inch spark, and worked by a six-cell primary battery.

Mr. Horace Wilmer and Mr. Staley having submitted to the operation of having their hands "radio'd," a conversation upon the general aspects of the new discovery followed.

Mr. SNOWDEN WARD, who had just returned from his lecture tour upon the same subject, made a few remarks upon the subject of the irregular action of the radiant matter tubes and their life. He thought that much depended upon the position in which the tubes were placed for working in regard to the magnetic field of the coil, and said that the result of some investigations which he had been engaged upon—and which were, indeed, only partly completed—led him to think that a position in which the longer axis of the tube was parallel to the axis of the induction coil would be found to be most suitable to regular working and the life of the tube as well. Mr. Ward also referred to the fact that some Continental workers had claimed to make good results with an "influence" machine for exciting the tube.

Mr. ISENTHAL was understood to agree with Mr. Ward as to the necessity for placing the tube in such a position as would free it as much as possible from the influence of the magnetic field and lines of force of the coil. In regard to the suggested use of a Wimshurst machine, the climatic conditions

in this country, he stated, were altogether against such instruments, which were notoriously unreliable in action. He stated that, at the Salpetrière Hospital in Paris everything which could be done had been tried to ensure dry insulation, but without a satisfactory result. He, therefore, preferred the more reliable, if more expensive, coil for this purpose. He added, that he believed that, with increased knowledge and improved manufacture, the life of the so-called "focus" tube should be almost indefinitely prolonged.

A very hearty vote of thanks to Mr. Isenthal was passed by acclamation, in which both members and visitors, of whom a large number were present, joined.

On May 27 Mr. Frank Haes will give a demonstration of the Daguerreotype process.

Putney Photographic Society.—The annual Lantern-slide Competition by members of this Society was held at their new premises, Chelvertou Hall, Chelverton-road, Putney, on Wednesday, the 29th ult. Dr. W. J. Sheppard occupied the chair, and Colonel Gale kindly acted as Judge. There were 126 slides, consisting of twenty-one sets, submitted for competition, which proved to be rather a keen one, the Judge having to take great trouble before coming to a final decision. The awards were: Silver medal, Mr. W. F. Gorin; bronze medal, Mr. W. Martin; certificate, Mr. W. J. Colebrook.

Aintree Photographic Society.—May 1.—Three new members were admitted, making a total of fifty-nine. A paper should have been read on stereoscopic photography, written by Mr. Fenton-Jones, Secretary of the Hackney Photographic Society, but had to be postponed in consequence of the large amount of other business. It was decided to hold the third annual Exhibition of Works of Art and Photography towards the end of the present year, when the new and spacious public hall now being built for Mr. W. P. Hartley would be complete, and, instead of limiting the competitions to local societies only, the classes would be open to all. Further particulars will be published shortly, and societies generally are invited to take a note of this.

Bradford Photographic Society.—April 30, Annual Meeting, the President (Mr. Alex. Keighley) in the chair.—The PRESIDENT briefly reviewed the past work of the Society and its growth. At the preseut time there is a membership roll of 176 members, although the Society is only a little over sixteen months old. It owns a very good lantern and accessories, besides various other small items, although its subscriptions up to this have only been 2*s.* 6*d.* per annum, but a change has come, and the subscription is to be raised to 3*s.* 6*d.* per annum. Let us hope this will be more satisfactory. Still there is an old saying, "More have, more want." The minutes of the previous meeting were read by the HON. SECRETARY and adopted. The financial report for the year ending December 31 was read by the Hon. Secretary, which was very satisfactory, showing a balance in the Society's favour of 4*l.* 11*s.* 4½*d.* This was adopted amidst loud applause. The next business was the reading of a set of new rules, submitted by the retiring Committee. These were read by Mr. RAMSHAW, and to all intents and purposes were all that could be desired, but in all societies there are a few members who think they know best how to govern the affairs of the Society, and, of course, we have got a few of these kind of people amongst us, and the consequences were that nearly the whole of the evening was taken up by a lecture from one of the members upon the working of other societies, instead of getting on with the business for which the meeting had been called. Eventually he dried up, and twenty-three general rules were passed. The next was the reading of a set of competition rules, but, as it was getting late, Mr. LENA proposed that these be postponed until next Thursday. Seconded by Mr. W. MARSHALL, and carried. The next business was the election of officers. The following geutlemen were elected:—Mr. Keighley was re-elected President unanimously. Mr. A. P. Rendell, Mr. Walter Booth, and Mr. F. J. R. Sutcliffe were elected Vice-Presidents. The retiring Secretary was proposed for re-election, but, as it was impossible for him to work in harmony with one of the Vice-Presidents, he would not stand, therefore the election of Secretary and Treasurer was postponed until next Thursday. The following gentlemen were elected on the Committee: Messrs. H. Cousen, George Swain, S. Hill, F. Nicholson, W. C. Ramshaw, Peel Wilkinson, Rev. W. H. Eastlake, Messrs. W. A. Bell, George Thistlethwaite, and P. E. Newstead. A vote of thanks was proposed to the retiring officers by a member who, only a fortnight previous, had proposed that a vote of censure be passed on the Committee for its shortcomings. The proposition was carried. The PRESIDENT briefly acknowledged the vote of thanks. According to the new rules, the night of meeting is to be altered to Monday, which ought to be a decided advantage, because it will allow of several members connected with another society of some importance in the town, and who are good amateur photographers, joining the Society, seeing that the night of meeting does not clash with theirs. It is to be hoped that on Thursday next the members will turn up in full force, as, in all probability, there may be some alteration in the general rules. Already the aforementioned knowing member has given notice that he will propose the rescinding of one of the rules he proposed, and which was passed. Let us hope that they will get over the work a little quicker than at the last meeting; and, if there are any addresses to be given, it would be as well if the members would reserve them for a future night, when the whole of the evening can be utilised.

Liverpool Amateur Photographic Association.—April 30.—Mr. DAVID LEWIS gave a lecture, entitled

500 MILES UP THE NILE, OR FROM CAIRO TO THE FIRST CATARACT.

He illustrated, with the aid of some 120 lantern slides, the interesting objects of interest at Luxor, Karnak, Assouan, and the island of Philal.

Oxford Camera Club.—April 27, Sir W. J. Herschel, Bart. (the President or the Club) in the chair.—A demonstration was given by Messrs. E. A. RYMAN-HALL and E. L. B. HILL, of

RADIOGRAPHY, OR PHOTOGRAPAY BY RÖNTGEN X RAYS.

A number of lantern slides were first shown, illustrating various objects taken by the demoustrators. Besides the radiographs, or electrographs, of animals, such as mice, rats, and a mole, showing the skeletons through the flesh, there was one showing a needle in the hand of a patient at the infirmary, this having been used to find the position of the needle, which, after having rendered the hand useless for nine weeks, was thus successfully extracted. A radiograph was then taken of Miss Herschel's hand, through her glove, and afterwards of that of Mr. G. J. Burch, both being developed before the end of the meeting with perfect success by Mr. Ryman-Hall. An interesting point was brought to light by Mr. Hill, who pointed out that we have in this process an infallible test for diamonds, the real article being quite transparent to the rays, while "paste" is very opaque. While the development was proceeding, experiments were shown with a phosphorescent screen, prepared with barium platino-cyanide. This was quite opaque to ordinary light, and the Crookes' tube was also enclosed in a cardboard box, so that it was quite invisible; but, on placing the hand between this box and the screen, the bones of the hand and even of the arm could be perfectly well seen in outline. Towards the end of the evening a half-sovereign was thus rendered visible through two fairly thick books. The electric current for working the Crookes' tube was supplied from accumulators kindly lent by the Electric Light Company.

Rotherham Photographic Society.—April 28, Mr. J. Leadbeater (Vice-President) in the chair.—The American interchange slides were shown. Excursioos to Piskhill and Blyth, Bolsover Castle, and Millers' Dale were arranged. It was reported that the balance-sheet of the recent Exhibition showed a profit of over 5*l.* Regarding the members' competitions the entries were slight. Mr. C. B. Keene, F.R.P.S., Derby, had acted as Judge, and his awards were as under:—Four prints (any process): 1, R. Chrimes; 2, Miss Crossley. Four silver prints: 1, Miss Crossley; 2, A. S. Lyth. Lantern slides: 1, R. Chrimes; 2, A. S. Lyth. Enlargement: 1, G. T. M. Rackstraw; 2, A. S. Lyth.

Stereoscopic Club.—April 27, four new members elected.—Mr. W. I. CHADWICK (the Hon. Secretary) exhibited a number of prints from negatives he had made by the X rays, many of them being interesting physiological subjects, which had been prepared previously to surgical operations. Mr. Chadwick said the apparatus necessary for the production of these X rays impressions was a powerful induction coil, with a suitable electro-motive force, a highly exhausted (vacuum) tube, and a photographic dry plate. The electro-motive force might be obtained from batteries or from a dynamo, or, in some cases from the street main. Bichromate batteries had the advantage of inexpensiveness; Grove's batteries were decidedly more steady and uniform in action, but the noxious fumes given off by them rendered them unsuitable for the library, study, or consulting-room, and storage batteries (accumulators) were much to be preferred; they were steady and constant in the discharge; clean, without smell; exceedingly portable, and would maintain their full efficiency for thirty or forty hours' solid work (either continuously or at intervals spread over a considerable period), and could be recharged at a cost of from 1*s.* 6*d.* to 2*s.* each. The induction coil used was one giving a four-inch spark in air, and provided with a suitably large condenser. This latter is a most important provision; and, in connexion with induction coils, Mr. Chadwick said that twenty years ago hundreds of scientific amateurs had a mania for constructing a large induction coil, and confessed that he himself was at about that time so affected; but the limited use to which powerful coils could be applied in those days soon caused them to be put aside as things of the past; but, since the publication of Professor Röntgen's discovery—we might say within the last three months—most of these old coils have been brought to daylight again, either to be pressed into service or to be disposed of at extraordinary high prices. It should be said, however, that many of the coils constructed in those days, even when supplied by professional electrical-instrument makers and dealers, are inferior to the modern instruments. The efficiency of a coil is not to be judged by its weight or its bulk. The vacuum tube of whatever form should be highly exhausted, and, to give a comprehensive notion of what high exhaustion means, Professor Crookes stated that the highest measured exhaustion 0·02 M* bears the same proportion to the ordinary pressure of the atmosphere that a millimetre does to thirty miles, or, in point of time, that one second bears to one year and eight months. Thus it will be seen that the making of these tubes is a tedious and a slow process, and, with a demand at present far exceeding the supply, the natural result follows that a large number of low vacuum tubes are placed upon the market, and these, for successful work, are practically worthless. The greatest care is to be exercised in the use of the tubes. The negative terminal of the coil should be connected to the cathode of the tube, and the positive connexion from the coil to the anode of the tube. If this point be neglected, the tube may be permanently injured. Sometimes it is an advantage to slightly warm the tube by a spirit lamp, and this may be done during use, but on no acconut touch the tube by the hand during use. A tube, after working for an hour or two, will sometimes refuse to work longer, as though it were fatigued; it should then be put away in a box, packed in cotton-wool, and, after a rest of a few hours, it will, in all probability, perform as well as ever. Respecting the best photographic plates to use, it does not necessarily follow that the most sensitive plates to daylight are the most sensitive to X rays, and this fact opened out a wide field for investigation, which he was diligently pursuing; many suggestions had been made during the last few weeks, and many statements had been made on the results obtained in exceedingly brief exposures, but most of these statements "broke down" on investigation. To say that practical results had been obtained in a second or two, or that the wrist bones had impressed the photographic plate, or that a developable image of the wrist bones had been produced in one minute, was untrue. Phosphorescent and fluorescent screens had, within the last few weeks, received much consideration and attention, and with some improvement, it should be said, but the best that had been done so far was very much inferior in definition—sharpness of outline—to the impression secured by the photographic plate. He had himself produced a fluoroscope by which it was

* M means one millionth of an atmosphere, so that 0·02 M means two hundredth part of one millionth of an atmosphere, an atmosphere = fifteen pounds per square inch = thirty inches of a column of mercury, or 760 millimetres.

quite easy to see the coins in a leather purse, placed behind a Slater's dictionary (a book four inches thick), but by the same appliances used under very similar conditions, he could not find a needle imbedded in the wrist of a patient, whilst photography quite easily revealed the lost needle. The interest manifested by the members drew from Mr. Chadwick a promise to give an illustrated lecture on the subject, with practical demonstrations, at an early date, and it was decided that members be entitled to invite friends, including ladies.

Patent News.

THE following applications for Patents were made between April 22 and April 29, 1896:—

PRINTING SURFACES.—No. 8390. "Producing Printing Surfaces by the aid of Photography." C. L. A. BRASSEUR and S. P. SAMPOLO.

PHOTOGRAPHY.—No. 8394. "Improvements in and connected with Photography." J. M. DAVIDSON.

SHUTTERS.—No. 8405. "Improvements in Shutters, Sheaths, Slides, and the like, applicable to Photographic Purposes." M. M. DESSAU.

KINETOSCOPE.—No. 8418. "Improvements in connexion with the Projection of Photographs of Animated Subjects." J. BONN.

COLOUR PHOTOGRAPHS.—No. 8663. "Improvements in Apparatus for Producing and Viewing Colour Photographs." W. WHITE.

POCKET APPARATUS.—No. 8790. "Improvements in Pocket Photographic Apparatus." COUNT T. D'OKSZA and G. BOURRELLY.

Correspondence.

DEVELOPERS AND THE SPEED OF PLATES.

To the EDITORS.

GENTLEMEN,—My attention has been called to a remark passed in one of your editorials with regard to a statement made by me at the Photographic Club: You say that Messrs. Hurter & Driffield's statement that *all* developers give the same speed is incorrect; to be quite strict, Messrs. Hurter & Driffield have not said this. In their original paper, they say it may be possible that some developer might be found which would give a speed different to the developers they tried at the time they wrote their paper. There has been so much misunderstanding, and so much antipathy to the views of Messrs. Hurter & Driffield, that it is necessary to offer some little explanation.

Some plates seem to show very little difference in speed readings with various developers; others, again, show enormous differences. What I implied in the discussion at the Club was, that considerable differences in speed could be obtained by varying the constituents of the same developer, but the reporter went a step further than this, and seemed to imply that Messrs. Hurter & Driffield claimed one speed for every developer; this, of course, they did not do, and I hope in justice to them that you will insert this explanation. It is a point now well acknowledged by all, and also by Messrs. Hurter & Driffield themselves, that different speeds can be obtained by varying the constituents of the same developer, but it does not follow that this admitted fact is universally true for all kinds of plates. I myself, with a view of trying to confirm or disprove Messrs. Hurter & Driffield's experiments, tried some experiments with some extremely slow plates of a particular make, and the result was that the speeds obtained by a great variety of developers were practically the same. I have even had the extraordinary result of one plate being practically three times quicker to ferrous-oxalate developer than to the pyro-ammonia developer I was using at the time; another plate, on the other hand, proved three times quicker to the pyro-ammonia than to ferrous-oxalate, thus entirely reversing the order of things. Considering the intricacies of photographic chemistry, I think that it would show a little better feeling if less hostility were shown to Messrs. Hurter & Driffield, and people more appreciated the valuable work which they have done. After nearly four years' constant practice of their system of speed determination, I am quite unable to find fault with the method; it is only a matter of practical detail as regards suitable standards for their system to be proved perfect in its practical application. They were the first to show the relation of density to speed, and as such deserve credit for this important work.—I am, yours, &c.,

Ashtead, Surrey, April 28, 1896. JAMES CADETT.

THE DALLMEYER-BERGHEIM LENS.

To the EDITORS.

GENTLEMEN,—In the discussion which followed the reading of Mr. Sutcliffe's paper at the Camera Club last Tuesday week night, mention was made of the Bergheim-Dallmeyer lens with respect to its great success in artistic portraiture, but there seemed to be a very prevalent opinion that its merits artistically were seriously discounted by its demerits practically, that it required too long an exposure. The impression seemed to be that one minute and a half at least was the necessary time.

In justice to the instrument, may I be allowed to say that I have seen it in work, and excellent portraits taken by it in from four to ten seconds, and I rather think that by now there is to be seen at the Camera Club a portrait, and as fine a one as could be well wished for, which was taken in eight seconds.—I am, yours, &c., ALICK COOPER.

Crichhton Club, 39, King-street, Covent Garden, W.C.

ASSISTANTS AND THEIR GRIEVANCES.

To the EDITORS.

GENTLEMEN,—I think a "Retoucher of Thirty Years' Standing" voices the general opinion amongst assistants when he says "that the time has arrived when something should be done." He also strongly recommends the formation of a Union. To form a Union would be an easy matter if only the necessary funds and members were forthcoming. At least 20*l.* would be required for printing, advertising, books, &c., to start a sound Union; and a hundred members would be sufficient to ensure its success. Given the funds and the members, it would need some energetic individual to work very hard for some weeks to organize, advise and correspond with members. Very few in the trade are in a position to give the time and money, or to devote their energies to making such a Union a sound and going concern. Once fairly started, however, it would be bound to succeed.

Failing a photographic Assistants' Union, there remains the alternative of joining some kindred society. I have lately been in communication with the leaders of several trade unions, and their opinion is that it is better to join some existing union rather than attempt a fresh venture. In short, they uphold a policy of "fewer unions and more union."

The "Shop Assistants' Union" is the best adapted to the needs of photographic assistants, and I am told that it already numbers some photographers amongst its active members. Its main objects are as follows:—

To reduce the hours of labour.
To secure fair payment for services rendered.
To regulate the relations between employed and employer.
To assist members when ill or unemployed.
To assist members to obtain a situation.

Now all these are precisely the objects for which a "Photographic Union" would strive. The subscription ranges from 2*d.* per week upwards, with special terms for ladies. The General Secretary, Mr. Jas. Macpherson, 55 and 56, Chancery-lane, London, will give all information, and give assistance to form new branches.

With respect to stating "who are the wrong doers," I may add that this can only be done effectually by trade-union methods, *i.e.*, by members making complaints at their branches, and the Secretary warning all members against the offenders.—I am, yours, &c.,

18, *Canbury Park-road, Kingston-on-Thames.* JOHN A. RANDALL.

AN AMUSING REPLY.

To the EDITORS.

GENTLEMEN,—I am in receipt of a letter from Mr. Richardson Brown which entirely relieves me of the paternity of the developer which has caused this little flutter.

Whether there has been a misprint, or whether the developer was put forth *bonâ fide*, I do not know; but, judging from a print which Mr. Brown sends (and to this extent Mr. Brown has a pull over his critics), there is no doubt that good average results are to be had by means of its use; I say average results advisedly, for, after all, they are no better than can be got by the use of formulæ which are more in the beaten track, and which, if not brilliant or eccentric, are eminently useful and satisfactory.

I really think I am the only photographer who has not invented a developer, and the thing seems easy enough too; but, from the chemist's point of view, when some of these formulæ are brought in, it is difficult to tell sometimes whether one is "making up" a spring medicine, a German mineral water, a weed-destroyer, or even an artificial manure!—I am yours, &c., J. PIKE.

Nottingham.

MONS. JARCHY'S BABY SHOW.

To the EDITORS.

SIR,—In reply to the remarques appeared in the last week Number, I beg to state that if the whorty correspondent who complain of not carrying out my scheme of a Baby Show will be manly enough to sign his real name and adress in the capacity of a speaking voice of several complaining about me, I will be only too glad to satisfy him *in extenso*.

"Poltrons" only hyde their name, and to those I never reply.—I remain, Dear Sir, yours respectfully, A. L. JARCHY.

45, *Union-road, Rotherhithe, London, May* 4, 1896.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & Co., 2, *York-street, Covent Garden, London.*

BRIGHT STOPS.—STOPS. Thoroughly clean the metal, and then, after making them hot, plunge them in a weak solution of bichloride of platinum and wash.

DISCOLOURED PYRO SOLUTION.—BEGINNER. If the solution were made up as directed, and it works satisfactorily, the slight discolouration may be disregarded. Certainly the straw-colour tint of the solution will have no effect on the permanence of the negative.

SPECIMENS.—OPERATOR. We should not advise you to send specimens of your work to the party named. We have had complaints, more than once, from those who have done so, of their not being returned, or anything heard from the people, even after repeated inquiries.

CARBON TISSUE.—JOSEPH HYMAN asks what are the colours used in making carbon tissue?—They are numerous; indeed, any pigment may be used, provided it is unaffected by the bichromate, and that it itself has no action on the gelatine or other constituents of the tissue.

REGISTERED TITLE.—R. A. BLACK says: "I should esteem it a favour if you would kindly let me know if the word 'Photo-chromo' is a registered title for coloured photographs."—In reply: We cannot say whether the name is registered; in all probability, not, as it is a very common one.

GELATINE FOR MOUNTING.—C. ROGERSON. The trouble has been due to employing an unsuitable gelatine. Coignet's gold medal is a gelatine that sets very quickly, and you require one of an opposite character. Try Nelson's "No. 2 Soluble," or a soup gelatine. Either will get over the difficulty.

PHOTOGRAPHING IN EPPING FOREST.—B, PUNFORD writes: "Will you kindly inform me if permission is required to take views in Epping Forest? If so, where can it be obtained?"—In reply: Permission is required, and may be obtained of the Town Clerk to the Corporation of the City of London, Guildhall, E.C.

COLOURING ALBUMEN PRINTS.—CLARA. A very common way to make albumen prints "take" water colours is to lick the surface over with the tongue. Another plan is to wash them over with ox gall, as sold by the artist's colourmen, highly diluted with water. A camel's-hair pencil, charged with water and touched with the gall, is sufficient.

FOREIGN WORK ON PHOTOGRAPHY.—MAX SEIGEL. We are not at all surprised that you have failed to obtain the work in England, as foreign works, unless they are translated into English, would have no sale here. However, any foreign bookseller will obtain it for you. Better still, perhaps, ask one of your German friends to get it in Berlin, and post it on to you.

BLOOD ALBUMEN.—A. Z. (Surbiton) inquires who are the manufacturers of blood albumen, as he wants a few pounds for experiments?—There are numerous makers of it, but it is very doubtful if any of them will supply it in small quantities. It may be had from Skilbeck Brothers, Upper Thames-street, E.C., but whether in such small quantities as our correspondent requires we do not know.

ALBUMEN PAPER.—C. TURNER. We have never heard of that brand of paper here. If you require it, you will have to get it direct from America. Probably it is the same as one or other of the papers supplied here—made in Germany—under another name. A few, very few, German houses supply albumenised paper, which is vended in various parts of the world under scores of different names.

PUBLICATION PHOTOGRAPHS; ADDRESS.—F. D. We have no recollection of such an advertisement; but the best way is to submit a copy of the photograph to the papers, and state your fee if they reproduce it. If you join the Photographic Copyright Union, it will give you all the information on the business side of the question. The firm named ceased to exist between twenty and thirty years ago.

WET COLLODION.—REPRODUCER. Some operators, we know, prefer the common copperas of the oil shops to the protosulphate of iron of the chemist for their developing solution. The reason given is that the former is, generally, more or less oxidised, and is found to give cleaner and denser negatives. On the other hand, unless it is made stronger, it is not so energetic a developer as the protosulphate.

PASSPORTS.—R. WADE. Passports are not necessary for Holland, Belgium, or Germany; but it will be well to be provided with one. It is little or no trouble to obtain, and its cost is but nominal. It is rarely useful, but, when it is, is of great value. An English passport should always be in the possession of an English photographer if he is going to photograph on any of the frontiers, especially the Franco-German ones.

SAVING RESIDUES.—T. ROMER writes: "I am an amateur and use a hand camera, and consume two or three gross of plates a year of the usual quarter size, and, beyond taking a proof print or so, put my printing out. Do you think it would ease the cost of photography to me, a not over-well-off amateur, to save the residues?"—No; it would certainly not be worth while, even if silver were double the price it is.

PHOTOGRAPHIC MATERIAL.—T. S. HARGREAVES. Messrs. Marion & Co., or any of the large dealers, will supply what you require. We cannot give you the addresses of the actual manufacturers, and, if we could, we doubt very much if they would supply you direct. The manufacturers of this class of goods only supply dealers on a large scale, and not consumers, who, perhaps, only require a gross or two of any one size occasionally.

LENS FOR COPYING.—PROCESS asks: "Which is the best lens for copying, the rapid rectilinear or the old triplet? I have heard some who use them say that the triplet is the better of the two."—The triplet is an excellent lens for the purpose, and so is the other. Some prefer one and some the other. Each has its advantages. In actual practice, as we learn from those who use both forms, there seems to be not much to choose between them.

COPYING DAGUERREOTYPES.—S. & Co. There is no difficulty in copying Daguerreotypes if care be paid to the illumination of them at the time. Arrange the light so that the buffing or polishing of the plate does not show on the focussing screen. Also see there are no reflections in the studio that fall on the plate. It is a good plan to cover up the front of the camera with the focussing cloth to avoid reflections from the camera and its fittings.

STAINED NEGATIVE.—FRED. JONES writes: "I unfortunately left a plate in the hypo all night, which has turned the plate a reddish colour. I shall be pleased to know if there is a remedy for same."—If the hypo was freshly made, we should not expect any discolouration that would materially interfere with the printing quality of the negative. If the stain is great, try the effect of a clearing bath of alum and hydrochloric acid, or alum and citric acid.

X RAYS.—S. E. WRIGHT. A coil that will give a six-inch spark, with three cells of Grove's battery, will do quite well for experimenting with the Röntgen rays, and such an instrument would be *very* cheap for 2*l.*; but, before purchasing it, see that it will do what is claimed for it. When new, it might have done so, but the case may be different now. The price makes us a little doubtful. Nothing is more risky than buying a second-hand induction coil without trial.

ADDRESS WANTED.—C. WEAVER says: "I recently bought, with other goods, a portrait lens bearing the name of Bourquin & Co. The balsam of the front lens seems to have gone wrong. Can you tell me the address of the firm, that I may send it to them to be set right?"—The address used to be either in Berners-street or Newman-street, if we remember rightly; but the house must have ceased to exist nearly, or quite, thirty years ago. The lens will be of French make, however.

WATER SUPPLY.—BARREL says: "Some time ago I attached a small barrel to hold water to the one side of my dark room; the water brought in with an Indiarubber tube and tap. The barrel was tarred to stop leakage. Now, I find, when the water is drawn off, it smells so bad that it cannot be used. Will you kindly tell me what I can do to clear it? Is it owing to the top of the barrel not being open, or the tar outside going through?"—The only remedy is to frequently change the water and not let it stay long in the barrel.

BACKING ENAMELLED PRINTS.—ENAMEL asks: "Would you kindly inform me what sort of paper would be suitable and chemically pure for stiffening enamelled prints? I am at present using ordinary drawing-paper (white), but I fear the result on the prints. Is there a paper sold for the purpose? I use a great deal, enamelling nearly all the prints sent out."—The purest paper would be that specially prepared for photographic purposes, namely, that known as the "Saxe," of Steinbach, or the Rives' paper. Either of these may be relied upon.

TONING DIFFICULTY.—W. K. S. writes: "Will you kindly inform me where I am at fault in toning my prints? I use Ilford (pink) P.O.P., and a fresh bath each time made the day I require it (sulphocyanide ammonium, 30 grains; gold, 2 grains; water, 16 ounces). They generally tone all right, but after washing in running water and before fixing they turn to a nasty greenish colour and remain so."—Unfortunately we cannot say, except that it is something in the manipulation. If the prints were treated in the usual manner, they would not behave in the way stated. Of course, without seeing the manipulations carried out, we cannot say how our correspondent has got wrong.

RESTORING DAGUERREOTYPE.—R. W. writes: "One of my customers is going to bring me a Daguerreotype, which he highly values, to restore and copy. I know that they can be restored; will you please tell me how?"—The picture can be cleaned by treatment with cyanide of potassium; but, if, as we imagine from the query, our correspondent is not familiar with the work, he had better entrust it to the hands of one who is, and not attempt it himself. The restoration of a Daguerreotype is a very simple matter with those who are familiar with the process, but many highly prized portraits have been utterly ruined by those who are not. The method of cleaning has been dealt with over and over again in these pages.

SPOTTY PRINTS.—T. W. R. writes: "Enclosed please find four cabinet prints, which, you see, are covered with spots, although they have only been done from three to four months. The one marked with a X was only printed a month ago, and yet it is covered with spots. They are very small, as you see, but they seem to get bigger with time. I need scarcely tell you that there were no spots upon them when they were sent out. I am now having prints brought back almost daily on account of spots, and it is threatening to do my business a serious injury. My printer says, and as I have kept a careful eye upon him I believe him, he takes every care in the fixing and washing. What can be the cause?"—In our opinion the cause is not far to seek. It is the bronze powder with which the name, &c., is printed. If the mounts be carefully examined, it will be found that they are studded all over, back and front, with the bronze, hence the spots. Avoid bronze printed mounts in future.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1880. Vol. XLIII.—MAY 15, 1896.

Contents.

EX CATHEDRÂ.

The success of the Leeds meeting of the Photographic Convention of the United Kingdom seems assured, and we should not be surprised if, in point of interest and numbers, the gathering surpassed its predecessors. Two months intervene between now and the opening day, and no more fitting opportunity, therefore, could present itself for the consideration of matters affecting the Convention meeting of 1897—that is, next year. With regard to that meeting, the Council are without any invitations, and there exists some doubt as to where it is to be held. This is a point upon which it is desirable that some discussion should take place.

* * *

Belfast has already been suggested as a centre, and we believe the local photographic Society, presided over by that firm and enthusiastic conventioner, Mr. Alex. Tate, would welcome the gathering; but it is pointed out, as a possible objection, that Belfast, for the majority of the visitors, would be found an inconveniently long way off; moreover, it is urged that Ireland was visited so recently as two years ago, and that the time for a second visit has not yet come round.

Geographically speaking, Norwich seems marked out for the meeting; it is the centre of a district rich in features of archæological, historical, and scenic interest, and could supply a diversity of other attractions. The East Coast, so far, has not been visited by the Convention. Everything, therefore, favours Norwich, except the unfortunate circumstance that there is no photographic society there to take in hand the work of organization incidental to the visit of the Convention.

* * *

This last objection also holds good with reference to Southsea and the Isle of Wight, which have been suggested as meeting places; Manchester and Liverpool, however, have not yet been visited, and are centres of photographic activity, with large and flourishing societies. Oxford, Bristol, Exeter, have also been pointed at as supplying suitable meeting places, so that a wide choice is before the Convention.

* * *

Should the Council fail to receive an invitation for 1897 from a photographic society having its home in a suitable meeting place, the obvious plan will be to revert to the course of procedure adopted in the early days of the Convention's existence, and itself select a town to be visited. After all, it is probably not vital to the success of the meeting that a formal invitation from a local society should be received. The meeting place having been decided upon, we are confident that a small committee of resident photographers could easily be formed to take in hand the preliminary arrangements, and, with the experience of ten years to draw from, there would probably be no difficulty in getting up a suitable programme, and successfully carrying it out, without the assistance of a photographic society. We suggest these points for consideration between now and the time when a decision must be arrived at as to the Convention meeting of 1897.

* * *

Mr. John Nicol has undertaken the editorship of our contemporary, the *American Amateur Photographer*. The name of Mr. Nicol will be familiar to our older readers as a frequent contributor to these columns some years ago. More recently he edited the Chicago *Photo-Beacon*, in which his admirable articles and pointed comments were conspicuously welcome features.

THE members of the Royal Photographic Society would appear to be taking more interest than hitherto in the selection of Judges for the forthcoming Exhibition, the nomination paper just issued containing the names of a greater number of suggested Judges, we believe, than the papers issued during the last few years. It may be interesting to give the names of those nominated to adjudicate in the Art and Technical Sections:—*Art Section:* Thomas Bedding; J. S. Bergheim; F. P. Cembrano; W. L. Colls; W. E. Debenham; W. Downey; W. England; Colonel Gale; J. A. Hodges; B. W. Leader, A.R.A.; Colonel Noverre; Andrew Pringle; G. A. Storey, A.R.A.; J. B. B. Wellington; B. Gay Wilkinson; W. L. Wyllie, A.R.A. *Technical Section:* Captain W. de W. Abney, C.B., D.C.L., F.R.S.; T. Bolas, F.I.C., F.C.S.; A. Cowan; Chapman Jones, F.I.C., F.C.S.; Andrew Priugle, F.R.M.S.; J. W. Swan, M.A., F.R.S.; E. J. Wall; Leon Warnerke; Paul L. Waterlow; Horace Wilmer; Sir Henry Trueman Wood.

* * *

IT will be observed that three artists—Associates of the Royal Academy—were nominated. The inclusion of an artist among the Judges is, we think, a risky thing, for this course is rarely attended by wholly satisfactory results. With an artist present, the awards are apt to create considerable mystification in the photographic mind, as was the case last year and the year before, when certain photographs of an obviously poor quality were selected for the distinction of a medal. The names of the gentlemen selected by the members of the Society to act as Judges will be found on page 317.

PHOTOGRAPHIC ASSISTANTS AND THEIR GRIEVANCES.

OUR correspondence columns have ever been open in the interests of photographic operatives, and the letters that have appeared during the last few weeks disclose a deplorable state of affairs as existing in some photographic establishments, unless, indeed, the cases are considerably overdrawn. It must not, however, even for a moment, be assumed that assistants are, as a rule, harshly dealt with in large establishments, for we know as a fact that, in the majority of them, they are treated with the greatest consideration and kindness, particularly the females. The letters we have received refer, we are pleased to say, to only an insignificant number of firms that are said to do large businesses in the cheapest kind of portraiture. According to some letters, it seems that not only are the *employés* compelled to work long hours in confined and ill-ventilated rooms for little wages, but they are subjected to great degradation in the shape of "bullying," &c., by the principals, on the slightest pretext.

This is a state of things that should not be allowed to exist; but where is the remedy? That is a question more easily asked than answered. But, if the facts be as stated, that the girls have to work long hours in crowded and badly ventilated rooms, the Factory and Workshops Acts will give an immediate remedy for that. Indeed, if the thing exists as said, it shows great negligence on the part of the factory inspectors for the districts in which the establishments are situated. If formal complaint be made to those officials, they will have to see that the Act is complied with. It is said that the *employés* are afraid to complain for fear of the after-consequences to themselves; but any one, even if not employed in the place, can put the law in motion. A letter, which will be treated as confidential, directed to the office of the Factory Inspectors, London, S.W., is all that is necessary. We believe that even anonymous communications receive attention, if there is reason to surmise that the writers have withheld their names through fear or intimidation.

With regard to the operators, and those who do not come within the scope of the Factory Acts, a remedy for their grievances is not easy to suggest, because the photographic labour market is so much over-stocked, except perhaps with the highest class of workers. As an instance, quoting from one of the letters, the writer says: "They (the assistants) are content to put up with any form of treatment, for they know there are more recruits on the firm to snap up their places if they should kick." The letter also refers to the salary of twenty and twenty-five shillings a week being paid for operators. Now, this at once proves, in a very practical way, that the labour market is much over-stocked, or such a condition of things would not obtain. While it does, we fear there is no efficient way of altering it.

At the present time there is really very little to learn in photography, as compared with the wet-collodion days, to qualify any one for an appointment in a third or fourth-rate studio, and that is the root of the evil; in any profession or calling where there is but little learning required the supply of labour is sure to be in excess of the demand. As a remedy for assistants' wrongs, it is now suggested that an Assistants' Union be formed. A Trade Union of photographers, to regulate wages, hours of work, and other trade matters, has frequently been suggested; and attempts have, more than once, been made to form one, but they have ended in failure, chiefly owing to the apathy of the assistants themselves. Judging from past experience, there is not a very promising prospect of one being formed at present, unless the assistants show more enthusiasm in the matter than they have hitherto done.

One has only to look back at the Photographers' Benevolent Association, now practically extinct, for confirmation of our remarks. This Association was established some years ago to relieve photographers in distress, and to find them engagements when out of employment, and other benefits. Although the subscription was but half-a-crown a year, scarcely any assistants were members, and, when the Association was on the point of being wound up, a meeting of assistants was called, to make an effort to keep it going, and extend its usefulness. We think we are correct in saying that less than half a dozen attended the meeting, and an invitation to a second meeting met with no better result. With these facts before us, the prospect of forming a Trade Union is not very encouraging, and it is much to be regretted that there is so little general agreement amongst photographic assistants.

As we have remarked on former occasions when dealing with this subject, photography is unlike any of the mechanical trades; the rate of pay can never be regulated by a Union, as it will always be regulated by the individual artistic and photographic ability of the worker. Some operators, so one of the letters states, are paid a pound, or five-and-twenty shillings a week, and possibly that may be as much as they are worth, while others command a salary of two or three hundred a year. There is, however, no reason why a Union amongst assistants should not be formed, if not alone, in connexion with another already in existence, as suggested in a letter last week, and we heartily wish it every success. If formed, it would, if not put a

stop to, at least act as a check upon such "sweating" syatems as those detailed in the recent correspondence.

As we have said before, it is only in an exceedingly few photographic houses that the assistants are so inconsiderately treated as they are in those alluded to by our correspondents.

A Monument of Astronomical Photography.—Some conception of the magnitude of the astronomers' work done at the Cape Obaervatory will be obtained by a perusal of the address of Dr. Gill, H.M. Astronomer at the Cape, at the last ordinary meeting of the British Astronomical Association. He referred to the starting, a good many years ago, with the aid of the Royal Society, to photograph a certain part of the heavens—from declination 18°S. to the South Pole. Every star up to 9·3 magnitude he believed was included in his finished work. The result was a catalogue of about 480,000 stars. This would be published in three volumes of about 800 pages each. The first volume was already completed, the second was in the press, and the third was to be ready for the printera before the first was out of the press, so that in about two years the printed work would be in the hands of astronomers.

Photographic Plates as Coronal Light Recorders.—At the aame meeting, various plans were suggested for utilising photographic dry plates to measure the actual luminosity of the coronal light. One member suggested that a print be obtained by contact (on a dry plate) from a sort of aensitometer scale; it would be easy, he said, to take a number of printing frames and expose them to the coronal light, which he anticipated would be quite easy, seeing that, in experimenta he had made with a thin negative by the light of the moon, he had found forty-five seconds sufficient exposure. They would have to be exposed, he would consider, at the bottom of a box to keep off light from the horizon. Seeing, however, that Messrs. Hurter & Driffield's system gives an exact measure of the relative value of light and density of the developed plate, it would aeem a simpler plan to estimate the light power by that system applied to unprotected plates exposed to the corona at the bottom of a box.

Portrait Lenses *versus* Reflecting Telescopes for Astronomical Work.—Mr. Isaac Roberts, F.R.S., whose magnificent photographic results with the nebulæ are well known, haa been making a series of exact experiments to ascertain the relative value of theae two types of image recorders, and his verdict is dead against the photographic lens. He used a Dallmeyer 3½ in. aperture and 9·56 focus, and a 5 in. Taylor patent lens of 19·22 focus, and his own large reflector telescope, all under aimultaneous and similar conditiona of light and exposure, and similar plates and similar developers. His reflector gave, in one region, 3·52 times more stars than the Taylor lens, and 7·78 than the Dallmeyer; and, in another, the increaaed resulta from the reflector were about double this. Dr. Gill, however, thought the mode of comparison quite unfair to the photographic instruments, and believed that, for the results to be accepted, instruments of equal light-gathering power, *i.e.*, diameter, should have been used.

The New Astro-Photography.—We have on previous occasions referred to the remarkable resulta announced by Mr. D. Packer in photographing the aolar corona in full daylight through opaque acreens, and last week a letter from him appears in the *English Mechanic*, dealing with the same topic. He says: "The latest feature in this new research is an important and very surprising one. It has been found that if a sheet of metal, or even glass, is exposed for a few seconds to the focussed image of the sun, immediately transferred to the dark room, and placed in contact with a photographic plate or paper for several hours, on development, an image of the solar corona makes its appearance. To obtain a good result, it is necessary to treat the metallic or glass plate as if it had received a charge of electricity."

A New Method of Using the Röntgen Rays.—In a recently delivered paper to the Paris Academy of Sciences, M. M. L. Benoist and D. Hurmuzescu have made a series of experiments from which they draw certain general conclusiona as to the mode of action of, and how to work with, the Röntgen rays: "The results which we have just stated seem to us to indicate in what direction future researches must be conducted in order to obtain preparations more sensitive to the X rays in photography than plates of silver gelatino-bromide. The salts of platinum, being more absorbent, will, doubtless, be more advantageous, which we propose to verify." It would thus appear to be worth while trying what the effect of the Röntgen raya would be upon platinotype paper. It is true that this paper is many hundred timea less sensitive to ordinary light than a bromide plate; yet, if these experimenters' conclusions be verified, it is quite possible that a practicable mode of working might be the result of the trial.

Diffraction of Röntgen Rays.—MM. L. Calmette & G. J. Huillier have submitted to the Academy some photographs obtained by passing the rays through through a slit in a metal screen, placed so that the rays could pass through it and on to a second metal screen, in which is pierced a slit with a thin metallic rod across it. After a description of their mode of working, and of the results they obtain by it, they sum up by saying: "If we compare these results with those obtained by light in the same conditions, the slit being relatively wide and the intensity weak, it aeems difficult not to ascribe them to diffraction." The negatives, however, are not aufficiently sharp to enable them to determine the wave-length with precision.

JOTTINGS.

EIGHT hundred and eighty millimetres of liquor ammoniæ, apparently recommended by Mr. T. O. Mawson on page 294, as a constituent of the bichromate aensitising bath for carbon tiasue, implies, on the face of it, that the volatile liquid referred to is aometimes quantitatively gauged by French linear measure, a thing which, to quote the Euclidian phrase, ia absurd. Second thoughts induce me to auppose that Mr. Mawaon intended to mix up ounces with cubic centimetres, but wrote millimetres instead. Still, thirty ounces of strong ammonia would obviously be too large a quantity for the bath referred to, so that the probabilities are that a smaller proportion of liquor ammoniæ ·880 was meant to be given, and that a typographical error is responsible for the confusion. Perhaps Mr. Mawson will kindly oblige with the necessary correction.

Little things, they aay, amuse little minds. But for this merciful dispensation, aome people would find life impossible to live. Among such I, of course, will not class Mr. S. Herbert Fry, who, under the *nom-de-guerre* of "Major Kone," relieves the monotony of his photographic enlarging labours by the monthly coutribution to a contemporary of a number of paragraphs which, if they are not consistently characterised by good taste and accuracy, rightly demand every indulgence in the way of criticism, by reason of the author's obvious ignorance of the nice art of differentiating, for publication purposes, between backstairs tittle-tattle and matters of legitimate public interest and comment.

Mr. Fry, however, atones for these inevitable deficiencies by the generosity with which he places his peculiar knowledge of photographic matters at the disposal of the all-too-limited public to whom he appeals. In contradistinction to the class of individual pointed at in the first line of the preceding paragraph, there are numbers of people who do not, or cannot, allow their minds to dwell on trifles. The Editor of this journal is evidently one, and he is therefore politely chided by Mr. Fry for being "ignorant" and "slipshod." The gravity of his offence is fully proportionate to the sweetness of the language adopted by Mr. Fry, for—will it be believed?—he was actually unaware that gelatino-chloride papers, in the many sizes to which they are cut, included the size 5½×4! Mr. Fry must be surprised at his own moderation.

There are some persons who might accuse Mr. Fry of giving way to that small weakness, so common among journalistic novices, of Editor-baiting, and he shows great courage in risking the accusation. But his long and intimate association with all connected with this JOURNAL clearly prove that he is not animated by any such juvenile motive. There are reasons, known to Mr. Fry, which would force any one familiar with them to be satisfied that his only object was to add to the sum of our photographic knowledge, otherwise he would scarcely expose himself to certain obvious retorts which a malevolently inclined individual might be disposed to fling at him in reply to his implied boast of knowing so much about the photographic trade and photographic paper-making. And then that unfortunate term "slipshod"—to how many things besides photographic editing (such as photographic trading), can it be applied, and with far more point and effect!

The financial position of the Camera Club Company is said to be, just now, not of the healthiest, and I suppose it was with the view of improving it that the suggestion was made to employ waitresses at the Club, who might, as occasion arose, act as models for those members of the Club who desired to go in for a little practical photography now and then. The suggestion, it appears, was rejected. It does not appear that the waitresses were expected to be willing, and qualified, to pose for "the altogether;" probably not, otherwise the suggestion might have been adopted, and a large influx of new members have resulted.

Undismayed by the imminent alarums and excursions of the Club Company meeting, however, the Conference appears to have passed off with great success, the reports supplying some unusually good and instructive reading. At the dinner Captain Abney chaffed the painters who are exhibiting at the Royal Academy for making much (unacknowledged) use of photography. The *Pall Mall Gazette* and Cassell's reproductions of the Royal Academy and other pictures are before me as I write, so also is the Catalogue of the Royal Photographic Society's last Exhibition. The reproductions of many of the Royal photographs—particularly the landscapes—make these out to be every whit as "pictorial" and "artistic" as do the reproductions of the Academy exhibits these latter, and the same holds good with regard to many portraits and figure studies. It is difficult, in fact, to say whether the originals are paintings or photographs. Have, then, photographers so much to learn from the painters, after all? or is it, as Captain Abney seems to hint, that the painters are not above imitating or copying from photographs?

The remarks on pictorial photographic portraiture (p. 295) made by Mr. F. M. Sutcliffe deserve to be pondered by every professional photographer who is ambitious to improve his work and exalt his calling. They tell him, in brief, how to become a genius; for Mr. Sutcliffe's remarks are, on the whole, a plea for taking pains—taking pains to avoid what he brusquely terms the "rotten foundations made on lies such as retouching, imitative accessories, sham landscapes, trees and plants." He also pleads for simplicity of treatment, subject, dress, background; letting the sitter alone; and—by-and-by—one sitter a day! I can forgive Mr. Sutcliffe this last and only real bit of extravagance in an excellent address, which a photographer should hang up in his room and study, for, far-fetched and impossible as some of Sutcliffe's ideas may appear to the sordid sweater, who by means of cheap labour supplies the common herd with *cartes* and cabinets at phenomenally low prices, the thoughtful, aspiring man must discern much in them that points the way to artistic and financial success in his profession.

Reading between the lines of the correspondence on the subject of "Assistants and their Grievances," it is not difficult to believe that, even allowing for some degree of exaggeration, which is pardonable in men and women smarting under tyranny and injustice, a vast amount of sweating still goes on among certain houses that are noted for the cheapness of their photographic productions. It is easy to sympathise with the poor wretches of men and women who have to submit to be ground down in wages; to work intolerably long hours under unfavourable conditions, and in other respects be treated simply as pieces of machinery for the extraction of profits at cheap prices; but it is far more difficult to offer any useful suggestions for helping them out of their troubles. An Assistants' Union would seem to be urgently called for—but who would join it? Not those who are satisfied with their position: so, whence would come the power of a Union composed of men and women with only a week between them and starvation? I hope, however, the correspondence on the subject in these pages will not be allowed to drop. By keeping the attention of the photographic world concentrated upon their grievances, by terrifying the sweating firms with the fear of exposure, much remedial good may ultimately be done by the victims themselves.

M. Jarchy, photographer, of Union-road, Rotherhithe, is like another great man, Mr. C. J. Rhodes; he does not care to face the music. Last September, M. Jarchy stated in print that he intended to hold a show of babies whose portraits he had previously taken *free*, and to offer three prizes, two medals and an oil portrait. Eight months have passed, and a resident in the South of London invites M. Jarchy to state why the Exhibition has not been held. M. Jarchy coyly declines on the ground that the inquirer withholds his name. Well and good; but the Editor of this JOURNAL, on p. 273, associates himself with the invitation, possibly so to have no room left for any refined scruples as to anonymity. So come, M. Jarchy, for the credit and glory of the noble industry of free portraiture, conquer your modesty, and tell us why the baby show was not held; or, if it is to be held, when? But don't call me a "poltron," please, or I may get angry with you.

COSMOS.

HALF-TONE SCREENS BY PHOTOGRAPHY.

II.

HAVING prepared a stock of dry plates, the next point is to prepare for making the reproductions, and here the beginner at that class of work must expect to meet with some disappointments, not only in connexion with the photographic, but also the mechanical, perfection of his work. It is very far from easy, except in theory, to obtain perfection of result in the comparatively easy work of reproducing line engravings, but, when we come to the much finer half-tone rulings the difficulties are vastly increased. In consequence of the fineness of the work, it is absolutely impossible to to watch the process of development in order to judge of density and clearness; this part of the work must be done entirely by time development with a standard exposure and developer, which, of course, have to be settled by practical trial.

Then, again, the mechanical and optical difficulties will be greater than would at first sight seem possible, and it will surprise most operators to find how difficult it really is to secure an absolutely faultless film, for the most minute imperfections that would pass entirely unnoticed in an ordinary landscape or portrait or even line negative will become painfully apparent in a "screen." And it will, perhaps, prove a revelation to many, despite the great perfection to which modern lenses have been brought, how difficult it is to secure equality of definition, and freedom from distortion, especially when the original has to be either reduced or enlarged; though, when the reproduction is of the same dimensions, *i.e.*, the same number of lines to the inch, the influence of the lens can be eliminated.

Under these latter conditions, instead of erecting the screen and copying it as one would an engraving or transparency, I prefer to place it in close contact with the sensitive plate, just as it would be used in making an ordinary half-tone negative. In fact, what is required is simply a dot negative, in which the dots are all of equal size, and this is secured by exposing to a plain white surface instead of to a half-tone picture. In this operation, while we are relieved of all care or trouble in the matter of gradations, we have to concern ourselves with the shape of dot and sharpness, and to arrange the screen distance and camera extension, as well as size and shape of stop accordingly.

Assuming that a cross-line reproduction as nearly as possible resembling the original in point of sharpness, but differing in the ratio

between black and white, is wanted, the way to proceed is as follows: The "stop" will have to be square, as the shape of the dot depends on that, and in order to secure the greatest sharpness, the distance between screen and plate should be as close as possible consistent with the securing of the pinhole lens action of the screen, which is essential in any variation of the size of dot. I speak of the size and shape of stop; but whether this is used with or without a lens does not seem to be very material, for a plain aperture in one end of a long box, if properly proportioned to the length of the box or camera extension, appears to act just as well as if the same aperture were used as a stop in conjunction with a lens.

The essential points to be observed are the adjustment of screen distance and camera extension to produce the alteration in size of dot that is required; but this, of course, will have to be arranged in connexion with a standard exposure and development, as before stated. Let it first be ascertained what exposure and what length of application of a given developer will give the necessary depth of deposit. Then, knowing the ruling of the original screen, and the extent to which it is desired to thicken the lines, or, in other words, how much smaller we want to make the dots than the clear apertures in the screen, it is an easy matter to roughly calculate by the rules of conjugate foci the relative positions of plate, screen, and stop for any size of the latter. Practically, the size of dot, with the standard exposure, will bear the same relation to the size of stop used, that the distance of the screen from the plate does to the length of tube or camera extension. But this will necessarily vary if the exposure be increased, the dot becoming larger, as well as losing sharpness; in fact, the whole business depends upon a very strict adherence to fixed conditions.

It is impossible, in the space at my command, to do more than indicate the lines on which to commence work, but any one accustomed to screen work will be able, in a very short time, to fix up things to answer his requirements, and those comparatively new at the work will learn more in half an hour behind the camera than by reading pages of description. In fact, the theory is plain enough, and it is only in the practical carrying of it out that the difficulties appear, and these can only be mastered by actual experience.

If a round dot screen or vignetted dots be required, a circular stop will have to be substituted for the square one, and, to secure the "softening," the screen distance must be slightly increased, or, better still, two or more exposures, carefully calculated, should be given, with stops of varying size, also calculated to give a dot decreasing in density in regular zones as the edge is approached. Here, again, users of the screen will know how to act.

The first result of this treatment will be a reverse of the ordinary screen, in fact, a series of lines of dots divided by transparent lines, a positive—in fact, from which a cross-line screen can be made by contact printing. But, as each additional exposure introduces fresh chances of defective plates, I prefer to arrive at the final result by the method of reversal with nitric acid or iron alum. This is quite easy under the circumstances of standard exposure and time development, and only necessitates a perfectly even film to commence with. Mottled or irregular films are, however, quite out of the question where reversal in this manner is to be effected, and, if it is not possible to secure the necessary uniformity, it will be far better to resort to the double operation.

In the case of vignetted screens in graduated dots the films may be stripped from the glass by any of the well-known methods in order to permit of the employment of the screens in printing from ordinary negatives or transparencies, an application of the vignette screen that is open to considerable development.

W. B. Bolton.

PHOTOGRAPHY AT THE NATIONAL GALLERY.

Another View of the Question.

This, like most questions, has at least two, and possibly many more than two, sides. One side has already been very ably put before the readers of The British Journal of Photography (page 290). The counsel for the defence has made the best that could be made for what we may call the conservative — or "we-are-all-right-as-we-are" side. But, alas for the perversity of human nature, the article referred to has not carried complete conviction to the present writer. Consequently, to say that the defence failed is only equivalent to saying that the counsel did the best possible with a very bad case. Who can make good bricks without straw?

It is a curious thing that we English folk are never weary of vaunting our freedom. Yet who can deny that we are bound to an interesting assortment of fetishes? One of them we politely term "vested interest." This is the deity which prevents slums being pulled down, roads widened, pure water supplied in abundance, and many public nuisances or inconveniences being removed: "Vested interests" float over the place, millions of people are awe-struck, and terrified into permitting the nuisance to continue.

Of course, the idea of any jealousy, or possibly rivalry, between the amateur and professional photographer is "quite too" absurd; for every one knows that the amateur is only an amateur, and therefore of no real or serious account. Still, it would be better not to alter the present condition of things; it might interfere, &c.

Let us examine, *seriatim*, the heads in the defendants' brief.

"The pictures are the property of the nation." True; but, as the nation is not composed entirely of *professional* photographers, it seems to follow that the amateur has equal rights with the professional. "The Trustees are their custodians." True again; but their function is stewardship rather than ownership, and hence it is part of their duty to see that the pictures are put to the best and widest use. "They are interested in the furtherance of art and its' study." From this it is argued that professionals are permitted to photograph the pictures because they will publish the copies. This, however, is not altogether proven. It may be granted that some, perhaps most, of the pictures are copied with a view to being sold generally. At the same time, it is not at all out of the question that some of the copies have been made by special request, and that one or two copies only were distributed. If a private person were to commission one of the authorised firms to copy some little-known *un*popular picture, he would expect to pay a substantial fee for the work, knowing that the professional worker might never sell a second copy of that particular subject. In such a case this would be of no great advantage to the nation at large. "The Trustees have in mind that the work should be well done or not at all." This is a neat way of saying that, if it has to be well done, it must be by the professional; in other words, amateurs are duffers at this kind of work. It is curious to notice that there are instances among living painters of repute who have actually been ignorant enough to prefer the rendering of their own paintings by the amateur to that of the professional.

Next it is urged that the amateur "simply photographs a picture for his own amusement," and "that, beyond his immediate circle, no one sees the result." This may or may not be the case, but it certainly is not the entire case; for suppose, if possible, an amateur who took his photography seriously, who made a real study of pictures, and did not treat the whole thing as amusement. Then, again, we might suppose this misguided amateur sending his results to a photographic Exhibition, where they might be seen by a considerable number of people, and meet with quite as much attention as a professional-made copy—one of many in a stock book or shop window.

"During the time the amateur would be at work he would be monopolising the picture from the public." True, but so would the professional. But why not let the photographers go into the galleries an hour or two earlier than the general public? As to monopolising the picture from the public, the time taken to photograph a picture, say a couple of hours, is as nothing compared to the time taken by art students copying. This may extend over months.

Next we have the argument "that the reproduction of pictures involving an immense amount of time, such as the professional is rarely able or willing to give, it may be fairly assumed that the amateur will monopolise the picture for a much longer time than does the professional. If that be the case, it is a strong argument in favour of the Trustees' refusal." Very ingenious. But bearing in mind that the Trustees recognise the importance of having the work well done, it would seem not impossible that an enthusiastic amateur who would not mind trying two or three times the same picture *might* get quite as good results as a professional who is neither able nor willing to give so much time to the work.

Then, it is urged that the camera man would add to the crowd on students' days. This is a question of degree, *i.e.*, depending upon the relative numbers of the two parties; but what are the reasonable probabilities? Suppose photography were restricted to the two students' days, and that we had, on an average, one camera in each room, how far would this one person add inconvenience?

The counsel, like a wise man, kept his trump card for the last trick This was the question of risk due to moving and unglazing. No one can

deny the risk. The writer would be the last to minimise this most important point, and fully recognises the importance also of reducing this to a minimum. At the same time it is only fair to point out that, if this risk is encountered, it seems hardly just that it should be wholly and solely for the benefit of the professional to the exclusion of the amateur.

Nor must we forget that the great part of the risk could be eliminated (*re* the glazing and unglazing) by a suitable lens hood, with a light frame for curtains, &c., to cut off reflections. Furthermore, it would be no serious matter to combine a camera stand of such a nature that a great many of the pictures could be photographed *in situ*, so that, so far as moving the pictures, there would be no risk at all.

It is, of course, quite possible to imagine an amateur, who is a duffer, who spends hours and pounds and produces only ghostly smudges, and at the same time to conjure up a philanthropic professional spending his skill, time, and money on copying pictures with the sole motive of bringing the National Gallery treasures into every home—*giving* his services, &c., to the lovers of art generally. At the same time, it is quite as easy to imagine our professional friend also a man of business, who deals with the photography of pictures exactly as the reproduction of maps, plans, &c., *i.e.*, entirely as a matter of business that will pay a reasonable return, and at the same time to suppose the existence of a capable and enthusiastic amateur, who is willing to devote his abilities, time, and money to the furtherance of reproducing and popularising the great art treasures of the nation.

It has been suggested that there is an impassable, mighty gulf separating the amateur painter and amateur photographer; but, after all does not this resolve itself simply into a difference of methods, a difference of degree, not kind? Both may be art *students* in the best sense of the term, the only difference between them being comparable to the difference between the painter and etcher or engraver.

At any rate, why not give the suggestion a trial? As a matter of fact, the number of amateurs at all likely to take up this particular line of work—difficult, costly, demanding skill, patience, and *taste*—is really so small, that the question of crowding is practically out of court. At the same time, the very fact of the difficulties being great, and the number of workers consequently being small, is in itself a most cogent reason why every reasonable facility should be offered to the photo-student.

F. C. Lambert.

INTENSIFICATION WITH BROMIDE OF COPPER AND NITRATE OF SILVER.

[Photographisches Archiv.]

A gelatine negative can be intensified to an exceptional degree if bleached in a solution of bromide of copper, for instance:—

100	grammes of	water,
20	,,	sulphate of copper,
20	,,	bromide of potassium,

and afterwards treated with a 10 per cent. solution of nitrate of silver.

This valuable process is, however, much neglected owing to the frequency of failure. Only the recognition of the cause of these mistakes can lead to a safe method of working. I have already drawn attention to several of these errors.

If, after bleaching, the washing is too prolonged, there will be no intensification when the plate is treated with nitrate of silver (*Archiv.*, 1894, p. 337). It must be remembered that the bleached image does not consist of pure bromide of silver, but contains bromide of copper in conjunction with the silver. The intensification is solely conditional upon this bromide of copper.* But the bromide of copper is easily washed out,† consequently the intensification does not occur.

If, after bleaching, the washing had been too short, the intensification, in this case also, could not have taken place. The film of gelatine would then have on its surface a protecting layer of bromide of silver, because the bromide of copper left behind unites with the nitrate of silver, and forms bromide of silver. Only after several applications, or strengthening of the nitrate of silver solution, will intensification take place.

* Because it reduces the nitrate of silver to metal. Nevertheless, the exceptional intensification is not thus entirely explained. According to usual chemical theory the bromide of copper can only reduce so much silver from the nitrate as was primarily contained in the negative. It is much more probable that the adjacent bromide of silver is converted into metal. In a theory of development, which I published some time ago (*Archiv.*, 1894, p. 305), the nascent metal unites with bromide of silver, but even this would only explain the formation of the latter, and not the metal.

† Carey Lea has shown (*American Journal of Science*, 1887, xxxiv. p. 384) that the silver haloids enter into closer combination with the haloids of iron, nickel, cobalt, manganese, and gold, so that the latter cannot be removed by washing. This disposition, however, is not noticeable with the salts of copper.

These occurrences, which usually appear as failures, may, however, be utilised for practical purposes. We propose to discuss them. I also desire to indicate some other processes that may lead to failure.

1st. A badly fogged, finished negative was half plunged into a solution of sulphate of copper and bromide of potassium, until the immersed half was thoroughly bleached. After washing for three hours in many changes of water, it was entirely covered for one minute with the solution of bromide of copper, and the other half bleached also. The entire plate was then rinsed in water for a few minutes, and placed in a solution of nitrate of silver. It intensified. The half which had only been treated once with the bromide of copper, intensified as much as the other, although the bleaching had only commenced. It also showed a strong deposit of fog. On the other hand, the half which had been treated twice with bromide of copper had almost clear glass in the shadows.

This phenomenon, which at first seems remarkable, can be easily explained, because the half that had first been dipped in the solution of bromide of copper had been washed for a much longer time after bleaching. In this way the clearest shadows and the veil, which lay over the whole plate, had lost their capacity for intensification. (The bromide of copper had been washed from those parts, and therefore the reduction of silver only occurred in the denser portions.)

The value of this process is very evident. If it is intended to intensify an over-exposed or otherwise veiled plate, wash it for some time after bleaching with bromide of copper. An under-exposed plate, in which it is necessary to bring up detail rather than greater contrast, should be washed but very little.

2. For the same reason, under similar conditions, a greater degree of intensification may be attained by rapid bleaching with a more concentrated solution of bromide of copper than with a weaker one. In the latter case part of the bromide of copper dissolves.

3. If the negative, after bleaching with bromide of copper, and short washing, is exposed to sunlight, it rapidly assumes a red-brown colour, and there is no appreciable intensification.

If the plate is now kept for half a day in a dark place, the colour disappears entirely. When experimenting some time ago, in connexion with the sensitiveness of copper salts to light, I had a similar experience. Paper prepared with chloride of copper was exposed and then treated with nitrate of silver. A remarkably intense image was obtained. (Here also the strong action of a cuprous salt upon nitrate of silver is apparent, as in the case of intensification with silver.) After keeping the picture a few weeks, I found upon inspection that the half-tones had faded and become an objectionable yellow colour. After a further length of time the entire image faded. (See also a paper by Ley, *Archiv*, 1896, p. 98.)

In both cases the cause was the same. Either there was unreduced cuprous salt in the film, or the cuprous salt absorbed oxygen from the air and passed into the cupric state. The latter then passed on a portion of its bromine or chlorine to the metallic silver and bleached it.

(Similarly the occurrence, which has been noticed before, of an exposed oxalate of iron paper, losing its power of development, after being kept for some time in the dark: the ferrous salt passes into the ferric state—see *Photographisches Archiv*, 1894, p. 321. I am making experiments to ascertain, if possibly the iron salt left behind in Kallitypes, or the addition of uranium and copper salts to collodion emulsion recently recommended by Valenta, operates prejudicially upon the permanence of prints.)

4. After intensification in the silver bath, the negative must be thoroughly washed, so that the remaining silver nitrate may not fog the plate when exposed in the printing frame. It is preferable, in all cases, to again fix with hyposulphite of soda. But, in so doing, great care should be taken. If the plate has been insufficiently washed, the intense black colour will entirely disappear. The salt of copper remaining in the film combines with the hyposulphite of soda, and forms a powerful reducing agent.

R. E. Liesegang.

VOIGTLÄNDER'S IMPROVEMENTS IN PHOTOGRAPHIC LENSES.

Messrs. Voigtlander & Kaempfer, of Brunswick, state that their invention relates to photographic objectives which consist of three lenses cemented together, or of two such systems of lenses.

Its object is to obtain a correction of the spherical aberration or an increase in the sharpness, which is rendered much more perfect than that of the objectives hitherto known, consisting of lenses cemented together.

And, in order to obtain the object in view, the invention consists in a photographic objective, which is composed of three meniscuses cemented together, viz. of two positive and one negative meniscus, the positive one

being between the other positive and the negative meniscus, both the last-named meniscuses having a greater refractive power than the intermediate or enclosed meniscus.

Such a system of lenses can be combined with a second equal, symmetrically or oppositely placed, system, or with a second unequal system, for the purpose of forming a double objective.

A double objective consisting of two equal systems of lenses, the one of which being symmetrical in relation to the other *i.e.* being the mirror image of the latter, produces also sharper images than the double objectives hitherto known.

By replacing in this double objective the one system of lenses by another, consisting of a double convex lens, a double concave lens and an intermediate positive meniscus, which latter has less refractive power than both the outer lenses, the advantage is obtained, that this double objective unites in itself the advantages or preferences of each of the two unequal systems of lenses. The system of lenses in which both the outer lenses

FIG. 1.

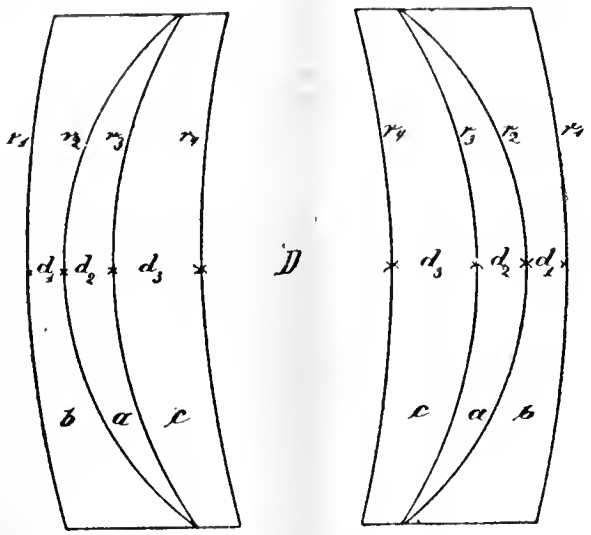

FIG. 2.

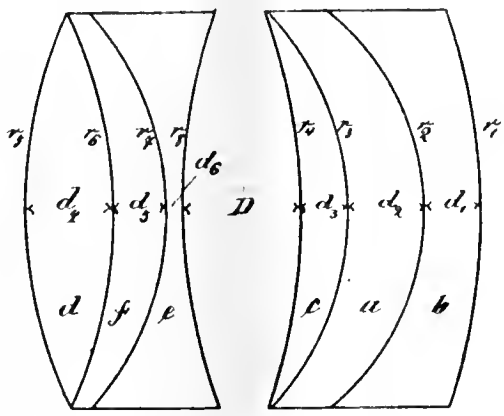

are respectively double convex and double concave allows a much more perfect correction of the astigmatism, whereas the other system, in which the outer lenses are meniscuses, does not allow this perfect avoidance or suppression of the astigmatism, but allows, as above mentioned, a much more perfect correction of the spherical aberration.

In the accompanying drawing

Fig. 1 is a double objective, which is composed, according to this invention, of two equal, symmetrically placed systems of lenses; and

Fig. 2 is a double objective, composed of two unequal systems of lenses.

In fig. 1, left-hand side, *a* is the intermediate positive meniscus, *b* the one outer negative meniscus, and c the other outer positive meniscus. The meniscuses, *b* and *c*, have higher refractive power than the middle meniscus, *a*.

In fig. 1, right-hand side, an equal but symmetrical system of lenses is represented.

The component parts of the objective shown in fig. 1 by way of example are as follows, if the focal distance is 150 $^{m}/_{m}$ and the aperture is 28 mm.

Radii of curvature.	Thicknesses of glass.	Distance between both the systems.
$r_1 = 49_{1}4$ $^{m}/_{m}$	$d_1 = 2$ $^{m}/_{m}$	$D = 10$ $^{m}/_{m}$
$r_2 = 16_{1}7$,,	$d_2 = 2_{1}7$,,	
$r_3 = 21_{1}95$,,	$d_3 = 4_{1}6$,,	
$r_4 = 62_{1}2$,,		

The refractive indices n are with relation to the Fraunhofer (Wollaston) lines D and F

for the lens *b* . . . . $n_D = 1_{1}5682$; $n_F = 1_{1}57637$
,, ,, ,, *a* . . . . $n_D = 1_{1}5262$; $n_F = 1_{1}53347$
,, ,, ,, *c* . . . . $n_D = 1_{1}6112$; $n_F = 1_{1}61873$

In the double objective, shown in fig. 2, the back or hind system of lenses (right-hand side) consists of three meniscuses, *a*, *b*, and *c*, whereas the fore system (left-hand side) is composed of a double convex lens, *d*, a double concave lens, *e*, and an intermediate positive meniscus *f*, which has less refractive power than the outer lenses.

The component parts of the objective shown in fig 2, by way of example, are as follows, if the focal distance is 510 $^{m}/_{m}$ and the ratio of the said distance to the aperture is 1 : $6_{1}3$.

Front system.			Rear system.	
$r_5 = 143$ $^{m}/_{m}$			$r_4 = 156_{1}92$	
$r_6 = 105$,,	$d_4 = 18$ $^{m}/_{m}$		$r_3 = 61_{1}806$	$d_3 = 11_{1}4$
$r_7 = 58_{1}4$,,	$d_5 = 10_{1}5$,,		$r_2 = 51_{1}366$	$d_2 = 14_{1}6$
$r_8 = 151_{1}8$,,	$d_6 = 4_{1}4$,,		$r_1 = 135_{1}49$	$d_1 = 13.$
		D = 24 $^{m}/_{m}$.		

The refractive indices are for the lens—

d and *c* . . . . . $n_D = 1_{1}6065$; $n_F = 1_{1}61404$
f . . . . . $n_D = 1_{1}5367$; $n_F = 1_{1}5441$
e . . . . . $n_D = 1_{1}5624$; $n_F = 1_{1}57022$
a . . . . . $n_D = 1_{1}5149$; $n_F = 1_{1}52156$
b . . . . . $n_D = 1_{1}5687$; $n_F = 1_{1}57686.$

The patentees' claims are for :—

1. In a photographic objective the combination of three meniscuses cemented together, the intermediate and one outer one of which are positive, whereas the other outer meniscus is negative, both the outer ones having greater refractive power, than the middle one.

2. In a photographic objective the combination of two equal symmetrically arranged systems of lenses, each consisting of three meniscuses cemented together, the intermediate and one outer one of which are positive, whereas the other outer meniscus is negative, both the outer ones having greater refractive power than the middle one.

3. In a photographic objective, the combination of a system of lenses, consisting of three meniscuses cemented together, the intermediate and one outer of which are positive, whereas the other outer meniscus is negative, both the outer ones having greater refractive power than the intermediate one, with another system of lenses, consisting of a double convex lens, a double concave lens, and an intermediate positive meniscus cemented together, the latter having less refractive power than both the outer lenses.

SOME WORK OF THE GLASS INSTITUTE AT JENA.

At a recent meeting of a scientific club at Hamburg, a number of statements were made regarding the work of Dr. Schott's experimental Glass Institute at Jena. This Institute is under the patronage of the Prussian Government, and its purpose is the carrying out of scientific and practical experiments in glass. That it has been fully successful in both is certain. The reputation of the optical and chemical glass made here, and the value of the additions which Dr. Schott and his associates have made to the literature of glass, give this Institute a unique position in the scientific and the commercial world. The success of the glass made here, says the *Pottery Gazette*, is to be attributed, first, to the fact that the number of the elements which may enter into glass as its principal constituents was greatly increased. It was found to be possible to introduce boric and phosphoric acids in place of silica in amounts up to 70·5 per cent., and to make good, durable glass, although the introduction of new bases was also necessary in using these acids. In place of the five elements used for so long a time, the experiments have led to the use of no less than twenty-eight, which can be contained in glass in quantities up to ten per cent. at least. The experiments have been almost entirely with optical and chemical glass, the endeavours being to find the very best glass for the purpose desired, and, at the same time, to establish the connexion between its properties and its composition. Samples of glass made in Jena have been tested by a number of eminent scientists to ascertain the coefficient of expansion. The extremes of the cubical co-

efficient of expansion have been thus found to be 0·00001097–0·00003369. Dr. Schott has, however, made glass with an infinitesimally small coefficient, and, on the other hand, glass whose coefficient is about that of wrought iron. Up to this time the linear coefficient had been put at 0·00000883. It has also been shown that there is a relation between the coefficient of expansion and the kind of materials in the glass, though the proportions of the same do not always exert a great influence. A large percentage of borax in the glass greatly lowers the coefficient of expansion. The great difference in the coefficients of various kinds of glass has been used by Dr. Schott to good advantage in the manufacture of his chemical glass and gauges, and also for thermometers. The glass tubes for the latter purposes are made of two layers of glass, one outside of the other, and these layers are of glass having different coefficients of expansion, that having the smallest coefficient being on the outside. There is a tension, then, away from the point where the two layers join, and, if the glass be suddenly heated, it will be far less liable to burst than a tube made of ordinary glass. For the manufacture of gauges a similar glass is used, only in this case the glass having the smaller coefficient is placed on the inside, and that having the greater on the outside, as the force to be counteracted in this case is not heat, but pressure. In addition, the glass used for the inside of such tubes must be of a composition that will resist water and steam under pressure and at comparatively high temperatures. These gauges are used in the German navy.

The resistance of the Jena glass to sudden changes of temperature is no less noteworthy. It may be heated to a temperature of 300°–400° Fahr., and then plunged into cold water without cracking.

Another specialty of the Jena Institute has been thermometer glass. After laborious experiments, Dr. Schott brought out a glass that is the most satisfactory for this purpose of any yet made, especially with regard to giving a thermometer with a zero point that does not change. His boro-silicate glass, the latest he has brought out, is about the ideal of thermometer glass.

Other ware, principally for chemical use, is made in large quantities here, such as combustion tubes, beakers, and bottles of highest standard of quality.

PHOTOGRAPHY WITH THE BICHROMATE SALTS.*

The concluding lecture of the series upon this subject, organized by the Affiliation of Photographic Societies, was delivered on Friday last, when Mr. W. T. Wilkinson dealt with *Process-work Applications of the Bichromate Salts*. He began by discussing the question as to which of the salts was most suitable for the production of a printing surface, and pointed out that, although bichromate of soda was sometimes recommended, it was almost certain to end in failure, on account of its hygroscopic nature; the potassium salt was most generally adopted, particularly in processes where gelatine formed the ink-bearing surface, and where it was not necessary to dissolve away the parts not acted upon by light; while bichromate of ammonium was best used with colloids soluble in cold water and which had to be dissolved to form the whites, as in photo-zincography. For photo-litho transfers in half-tone nothing equalled the Pretsch process, for which the following formula was given:—

A.

Kreutz's soft gelatine	50 grammes.
Clarified fish glue	15 ,,
Water	200 c. c.

In mixing, first soak the gelatine in the cold water and melt; then add the glue, stirring until it also is dissolved.

B.

Ammonium bichromate	4 grammes.
Water	100 c. c.

C.

Silver nitrate	2 grammes.
Water	100 c. c.

D.

Calcium chloride (crystals)	1 gramme.
Water	20 c. c.

To No. 1 add No. 2, stirring vigorously; next, still stirring, add No. 3; then add sufficient of No. 4 to just discharge the red colour (due to the formation of chromate of silver) and to turn the mixture white; and, finally, stir in eight drops of acetic acid and ten drops of glycerine. After straining through muslin, the solution is to be coated on collotype plates, previously prepared with beer and silicate, allowing six minims for each square inch of surface, and the plates can then be dried at a temperature not exceeding 130° Fahr. When dry, the plate is exposed under a reversed negative until all details can be seen on the back of the plate, when it must be plunged into a warm saturated solution of borax, washed in clean cold water for three or four hours, and dried and etched. Printing is performed as from an ordinary collotype plate, using transfer ink mixed with collotype printing ink, and pulling the transfers upon a good, well-rolled Scotch transfer paper a little hard from age, and they must be put down upon extra smooth stones in the usual way. For photo-zincography and for printing on the metal, Mr. Wilkinson recommended bichromated albumen, the ammonium salt being preferred as sensitiser. For half-tone the same was largely used, but better results were obtained with fish glue, or gum senegal and albumen, the image being subsequently carbonised in order to confer acid-resisting powers. The lecturer next traced the history of Fox Talbot's photo-engraving process, and expressed his opinion that the finest results in photogravure were secured by first coating the metal with a solution of bichromated fish glue, drying, exposing under a single ruled screen of from 200 to 300 lines to the inch, developing in cold water coloured with aniline, and washing, and drying, and burning in. On this ground a carbon negative print could be mounted and developed, or a thin film of gelatine could be spread over it. Other methods of photogravure were also described, and the fact was emphasised that each of the processes which had formed the subjects of the course of lectures required its own particular class of negative, and that the negative must be made for the process, and not the process made to fit the negative. Mr. Wilkinson passed round for examination some examples of three-colour collotype, and specimens of calico and velvet, printed and embossed by means of rollers, upon which the patterns were produced by photographic means. He said the latter process was an entirely new application of photography with the bichromate salts, but he gave no details of it except that photo-lithographic transfers were transferred to the rollers and then etched, the ink acting as a resist. By this means the production of rollers for calico-printing, velvet-embossing, the production of Lincrusta Walton and similar materials could be carried out much more rapidly and cheaply than by ordinary methods. He had been working at the process for the last two years, and this was the first occasion upon which it had been publicly referred to.

A vote of thanks was accorded to Mr. Wilkinson for his lecture, and the Chairman, Mr. W. Thomas (the Chairman of the Affiliation Delegates) made some remarks with reference to recent adverse criticisms of the Affiliation scheme in a certain photographic journal, which had described the Affiliation as a corpse. Mr. Thomas, at some length, detailed the work which had been achieved since the inception of the scheme, including the courses of lectures on photogravure, colour photography, the science of development, and the present series, and also the meetings of Judges for formulating regulations as to Exhibitions, and the conference of secretaries of the affiliated societies. He vigorously defended the Affiliation against the "sniggering attacks" of certain papers, and urged the delegates to continue to work steadily and strenuously at the objects in view.

* Concluded from page 295.

THE AFFILIATION OF PHOTOGRAPHIC SOCIETIES.

[London and Provincial Photographic Association.]

The fourth year's work of the Affiliation Committee having closed, I feel it my duty, as one of your delegates, to make a report of what has been done, and give my opinion of the future of this Committee. It has been given a fair chance of securing a position in the photographic life of the country, and, as application has been made for the renewal of our subscription, before asking you to vote, I feel compelled to take your opinion upon the probability of any further useful work commensurate with the expense incurred.

After the formation of the Committee, a lecture was given by Professor Meldola, in which he referred to the work that might be undertaken by the Royal Photographic Society through this channel, and he recommended a Technical Institute as the goal of our efforts. It will also be remembered that, after the abortive scheme of Mr. Biden, the Royal Photographic Society placed itself at the head of this scheme of Affiliation, sketched a programme, and invited the attendance of delegates from the other photographic societies to discuss the matter and carry it into effect.

I was sent as one of your representatives, and must say that, after the first meeting, I had considerable doubt of the success of the movement, as the parent Society seemed far too anxious to retain absolute control over the Committee. At the same time it was very sparing of its liberality in the financial arrangements. It insisted on the right of veto in any work we might undertake, and asked for half the subscriptions for secretarial expenses and use of rooms. But, though the parent Society claims so large a right in the management, and has three delegates, it makes no contribution to the funds. It stipulated for all the power of a parent, but repudiated its duty of support. In fact, we were given to understand that we must provide for our own maintenance. Such were the conditions of our start in life, and it is not surprising that we have failed to reach manhood. We made a bold struggle for existence, and I look upon the first two years of our work as fairly prosperous, considering the disadvantages under which we laboured. In those two years we gave two courses of lectures, the subjects being *Photogravure* and *Colour Photography*. We made several collections of lantern slides, which have had considerable circulation, we tackled the knotty question of judging at photographic Exhibitions, and some lectures were given gratuitously by our old friend, Mr. W. E. Debenham, before some of the affiliated societies. The lectures on *Photogravure*, by Mr. Denison, of Leeds, are deserving of special mention, as they were the first of the kind, and gave a decided impulse to the process in this country. Meanwhile, the weaknesses of the scheme had made themselves felt. We were delegates

from societies scattered throughout the country—even India was represented—but at what points were our interests in common? Our funds were far too small to permit even the thought of founding a Technical Institute or school. We were all anxious to secure material for the programmes of our individual societies, but for this purpose also our means were too limited, and we could not afford to send out lecturers. Other questions, such as securing greater facilities for railway travelling, were considered; but, with regard to the railway companies, I must say that the half-hearted manner in which the request was made rendered the prospect of failure almost certain. Had there been an honorary secretary with some enthusiasm for the work, petitions might have been presented from the societies throughout the country, members of Parliament might have been approached, and, though it is easy to make unwarranted assumptions, I think some minor concessions would have been obtained, if even a full measure of success was impossible.

During the last two years the difficulties of our position have been so apparent that little else has been undertaken other than the annual lectures; but, throughout the whole of these four years, what help have we had from the parent Society in accomplishing useful work of importance, or in attempting to realise Professor Meldola's idea?

I think I may say that the assistance has been merely nominal until this year, when the room of the Society was placed at our disposal for the lectures on the bichromate salts. It may savour of ingratitude, but I venture to say that this service has been of very little use. Situate at the west end of the town, the room is of no practical value for such a course of lectures. It is out of convenient reach for most of the London societies, and I would strongly advise, in the event of future lectures, that a room in the City be selected. That these lectures should now be the only useful work of the Affiliation Committee is strong evidence in favour of Professor Meldola's idea that a Technical Institute should have been the aim of the parent Society.

And now as to the future. I think these lectures, if they are to be continued, can be as well carried on by the parent Society alone, and I would therefore recommend that this Society withdraw from Affiliation. I see no adequate result for the money spent by the Committee, and I am strongly of opinion that the Committee should be now dissolved. If other societies will follow in the steps of the London and Provincial, the Royal Photographic Society will have to reorganize the scheme, carry on the work alone, or abandon it altogether. We shall then ascertain if it has any real interest in organizing the photographic societies throughout the country for a common purpose, whether it desires to be the centre from which a Photographic Institute may spring, or whether it will follow in the footsteps of some other learned societies and retire to the respectability and somnolence of a west-end square.

If the Royal Photographic Society desires to increase its power and influence, it will keep in touch with the best and largest of the photographic societies throughout the country. As a means to such an end, I would suggest that, in place of the Affiliation Committee, the Royal Photographic Society should offer membership to one or two delegates from each approved society on the same terms of subscription as to the Affiliation Committee. It is as much as most of the societies can afford for such a purpose. A scheme on these or similar lines would gradually centre activity in photographic matters in the Royal Photographic Society. Should any subject of general interest then arise, or should common action be necessary, these members would feel it their duty to ask the co-operation of those societies they represented. In this way there would be constant means of communication and community of interest, and the best blood of the societies would be drawn to the parent Society, and it might then reach the position of an influential body reflecting the opinions and aspirations of photographers throughout the country. A royal charter may be of considerable financial value, but the letters F.R.P.S. will be a mere empty appendage unless the Society attains a commanding position.

P. Everitt.

A SYNOPSIS OF THE PROGRESS IN THE NEW RADIATION.

[Photographic Club.]

When your Secretary some two weeks ago kindly asked me to give you an evening's discourse on the new radiation, I felt some diffidence in bringing before you again a subject which had been so ably and fully demonstrated to you but a short while back by our co-member, Mr. H. Snowden Ward, and which has since been mentioned, *ad nauseam*, in the professional and lay press. But, on second consideration, I decided that it might, after all, prove interesting, and perhaps useful, to the members, or at least to those who follow the development of this new branch of our science or art (?), to have a synopsis of the progress made since the first announcement of the discovery by Professor Röntgen.

It must have struck even the casual observer that the literature which the new discovery has called into existence is unparalleled in the annals of scientific evolution, taking into consideration the very short time of its existence, and to the careful and interested observer the mass of facts brought to light is bewildering, more especially since many of these facts, or at least reports, are so diversified, contradictory, vague, and irrelevant. As a matter of fact, the subject is so very abstract and of such intense theoretical and practical interest, that a systematic and exhaustive classification of the various rediscoveries and observations would be by no means an easy task, and at some later date would be well worth the attention of our great scientists. What I can do this evening is simply to consider the whole subject of X ray photography, or shadography, or radiography, or whatever else you may please to call it, from five distinct points: (1) The question of priority of discovery; (2) the advances made in its explanation; (3) the improvements effected in the means of working; (4) the practical results obtained; and (5) its inherent possibilities.

Taking first the question of priority, it would have seemed almost ridiculous to pause for a moment to discuss this point when the discovery was first announced. But since then a host of disappointed, and up to now more or less obscure, amateur experimenters has suddenly sprung into temporary existence, who claim priority, and I do not think it advisable to waste your time in enumerating them; but I should like to express my surprise that one of our leading electrical periodicals, in a recent interview with Mr. H. Jackson, of King's College, has thought fit to pose this gentleman as having anticipated all Professor Röntgen's work. There is no doubt that the chain of scientific progress which has made Röntgen's discovery possible has been chiefly made in England, if I may be allowed to use a very hackneyed expression. The splendid researches of Clerk-Maxwell, Lord Kelvin, Professor Crookes, and Professor Lodge have decidedly been most important links, without which this latest addition to the science of electro-optics would never have been made; but the subsequent work of Hertz, Lenard, and Röntgen is unique, and ought not to be made the subject of international jealousy. Science is the inheritance of mankind, and its furtherance the duty of the human race irrespective of nationality.

It is certainly no mere chance that great discoveries are so very often made almost simultaneously by some kind of mental telegraphy, and spectrum analysis, the discovery of the mechanical equivalent of heat, the telephone, &c., furnish points in question; but the credit of every discovery must be given to the man who is the first to publish and scientifically investigate it.

It is not so easy to dispose of the second point. There are at least a dozen different theories brought forward to account for the properties of the new radiation, and some of these theories, in order to sustain their useless existence, have to depend upon most unscientific assumptions.

Briefly stated, there are at present three *reasonable* main directions along which the explanation of the new rays may be expected. First, there is the theory that these radiations are the long-looked-for longitudinal vibrations of "ether," and this theory has the weighty support of Lord Kelvin and Professor Röntgen himself. The second theory (which represents the majority of English scientific opinion) is that the X rays are transverse vibrations, similar to ultra-violet waves of minute wave-length; and the third regards the action of the rays as some mechanical manifestation of a stream of material particles propelled with tremendous force, somewhat similar to a refined sandblast.

It would carry me too far to attempt a review of the *pros* and *cons* of these three theories, and, being exclusively of an electrical nature, it would certainly not come within the scope of this Club, so we will pass on to the more practical third point under consideration, namely, the improved means of working with the X rays; and here it may safely be stated that the most important progress is due to the experiments of English investigators.

When, shortly after the publication of Professor Röntgen's paper, some few experimenters who were fortunate enough to possess the necessary apparatus took up the work, they were obliged, owing to the meagre working instructions given by Professor Röntgen, to find out the best practical conditions, and naturally they started with Crookes' tubes, which they happened to possess, and which were, as it turned out afterwards, most unsuitable. In order to improve upon their results, they tried more powerful apparatus, higher electrical vibration frequencies, and the like, and so we find Mr. Campbell Swinton at first emphasising the necessity of using so-called "Tesla" currents. Perhaps few of you realise the difficulties and inconvenience of this otherwise most interesting and promising Tesla apparatus; but suffice it to say that it requires very skilled electrical manipulation, that it is a complicated arrangement, and that special tubes are required. In addition, the noise it makes is sufficient to shake all but very hardened nerves. (I have here a very small sample of this noise, which I hope you will appreciate.)

The chief characteristic of a "Tesla" coil, as compared with an ordinary "Rhumkorff" coil, lies in the fact that, whereas the latter, by means of its electro magnetic interrupter, only breaks the current about 150 to 250 times per second, the "Tesla" coil is worked with oscillating currents surging to and fro several million times per second, which high rate is attained by the use of a condenser or Leyden jar spark gap; and it is this latter which causes the above-mentioned objectionable noise.

Very soon, however, it was found that equally good results could be obtained by using the ordinary induction coil alone, and so we find very few experimenters using the "Tesla" arrangement to-day, although Tesla himself has naturally been working with his apparatus and obtained excellent results, particularly as far as penetrative power is concerned. (He obtains shadowgraphs at forty feet distance.)

As regards the size of the induction coils used, the length of the spark very soon reaches a limit in radiography, very long sparks being un

pleasant things to work with, and also apt to injure the tubes. A six-inch or eight-inch spark is sufficient for any case, and little is gained by increasing it.

The most important item, however, is the vacuum tube, and it is here that most important advances have been made.

It was at first generally assumed that any vacuum tube of very high exhaustion was suitable for the work, and so there exist a number of various shapes, &c., which, although of very good quality as regards exhaustion, necessitated what we now consider long exposures (say, twenty-five minutes for a hand), and which also failed to give the desired definition of the images. As long as a tube showed the characteristic apple-green fluorescence, it passed as suitable. Of course, as in the case of ordinary light, the more the source of the radiation approaches the size of a point, the sharper would the shadows be, and this condition was far from being fulfilled in the early tubes, the fluorescent patch on the glass from which the X rays were supposed to emanate being about one to two square inches in area, and so causing indistinct images.

A really important step forward in the construction of the tubes was made when it became generally acknowledged that the place or point from which the X rays start is always that portion of the tube where the cathode rays (that is, the stream of electrified particles shot off from the negative pole) strike against a solid substance. In the case of the older tubes with flat cathode discs, the cathode rays were a cylindrical bundle which was intersected by the tube wall, and so produced the X rays from a round area. (Demonstrated.) On making the cathode a concave disc, the cathode rays are given out as a cone-shaped bundle, and if we place a solid substance in or near the centre of curvature of this disc, or, in other words, in its focus, we have the X rays starting from this focus point, and thus get what we want, namely, definition. The solid in the focus is mostly a plane piece of platinum, as it will allow no X rays to pass through, it being very opaque to them, but will reflect them or send them all outwards on to the object to be radiographed. This tube, which is said to have been elaborated by Mr. Herbert Jackson, of King's College, is, in fact, a tube which has been used by Professor Crookes in 1877, although for different purposes. We also know now that the green fluorescence is not essential to the presence of X rays, but is a secondary phenomenon, so that a tube may work very well, even if it remains almost dark.

Another point lately recognised is that the vacuum of a tube increases after prolonged use, so that it requires higher electrical pressure (a longer spark) to send the electric discharge through it. It is assumed that the metal electrodes inside the tube absorb some of the remaining oxygen in the tube, and, in order to bring the vacuum again to the proper degree, the tube will have to be put on the mercury pump again, or, for temporary repair, it may be warmed, in order to liberate the air which is condensed or adhering on the inner walls.

The various attempts made to replace the glass walls of the tube, which are rather opaque to the X rays, by aluminium, are not practicable yet, and introduce a lot of mechanical and electrical difficulties without corresponding gain.

The last, but not least, important requirement for the production of photographic records of these shadows is the plate. It was at first assumed that, as the new radiation was most likely very different from light, the speed of the plate was of no importance; but I think every one who has tried his hand at the new game will find that a very rapid plate, and one which is rich in silver or thickly coated, will give the best results.

In this connexion I venture to suggest the value of intensification in order to increase the contrasts; and it has been my invariable practice, when developing radiograms, to underdevelop the plates with hydroquinone (giving chalky negatives), and to strongly intensify them after.

In confirmation of my remarks in the preceding paragraph regarding the speed of plate required, I can only refer to an experiment I made some few days ago, when I had to increase the exposure of a certain object to *treble the amount*. All other conditions remained unaltered, but I was using a somewhat slower plate.

I personally do not think that very much can be done to improve upon or adapt the present plates for X ray work, unless we coat them more heavily, and perhaps embody certain substances like fluor spar with the emulsion. This is likely to do away with some of the definition.

Of the various attempts to decrease the exposure necessary for shadowgraphs, very few of those that have been suggested have survived. We hear now little or nothing about the effect of warming the plate or steeping it in chloride of iron or sulphate of quinine, &c., or taking eosine orthochromatic plates.

A series of most promising experiments, however, that have lately been carried on at the University of Jena should be mentioned here, as they are likely to prove a step in the right direction. It has been often suggested to increase the X ray action by placing a fluorescent screen, such as I shall describe later on, in contact with the film; but this rather tends to scatter and diffuse the light, and, as Professor Oliver Lodge points out, "this would be a poor exchange for the straightforward penetrating power of the X rays, and may be a step backward."

If, however, fluor spar in plates or in the crushed state be brought into contact with the sensitive film, a new kind of rays, likewise invisible, not fluorescing, are produced, which, acting back on the film, increase its sensitiveness to X rays about one hundred times, so that a few seconds' exposure will produce the same results as do now two minutes; but this process is far from complete, and much remains to be done.

There will be most naturally a certain granular or marbled appearance of the plate after development, but I scarcely think this matters much, as it does not interfere with the proper diagnosis of fractures and dislocations, &c., and even the location of needle fragments, &c., will be possible.

As regards the practical results obtained, they have, up to the present, been chiefly of benefit to the medical profession, or, more strictly speaking, to the surgeons. There are a few isolated cases of technical and industrial applications, but they are few and far between.

The surgeons, however, have certainly every reason to congratulate themselves on this latest acquisition.

The number of bullets, fragments of bones and needles, found in the extremities and body is remarkable, and make us wonder how the world got along before Röntgen's discovery. The X rays have been showing us foreign bodies accidentally swallowed or lodging in the pharynx or gullet; they have shown us the blunders made by surgeons in setting fractured bones, &c., and they have also somewhat modified the views held even by eminent physicians as to the position of certain bones in the body.

I have here, through the courtesy of Mr. Vasey, of the *Lancet*, some specimens of the most remarkable cases which have come under his notice, and which I shall pass round. They are rough proofs only, as the negatives have been mislaid. In addition, I pass round some of my own results, and later on will show some slides. But these results, perfect as they are, do not suffice, and the question I am almost daily asked by doctors and others interested in the process of radiography is, Will it be possible to photographically record, or even to see by means of the screen, the internal non-calcinous or non-osseous parts of the body, such as heart, lungs, kidneys, &c., and also such highly inconvenient formations as gallstones, tumours, &c.? And the answer to this question, which is in the affirmative, brings me to our next and last point, the possibilities inherent to radiography.

It has of late very often been stated that the electrician has done for the new process as much as his science or art will permit, and that it is now for the photographer to further improve and perfect it, a prospect which would be very cheering, as it would add another very lucrative field to the operations of the professional. Well, I am afraid that I cannot quite see matters in this light, and for the following reasons:—

It has recently been found that what we are wont to call X rays are in reality a bundle of X, Y, Z, and ever so many more mysterious and unknown rays, which have all different properties—in other words, that the X radiation is heterogeneous (similar to a bundle of light rays of various colours, which would affect an ordinary plate to a different degree).

Some of these rays, let us say the X rays, do not penetrate bones and metals, and so produce the shadow pictures with which we are now familiar. As all our results are so far alike, save for details, we must assume that these X rays are largely preponderating. It is, however, possible to place the Crookes' tube into such an electrical condition that these bone shadows do not appear, which shows that, under certain circumstances, Y or Z rays are in abundance, and of X rays there are but few. It is by no means improbable that in this difference of penetrative power we may look for the ultimate solution of the problem to make the whole internal mechanism of the body visible. The conditions governing this different emissivity of the tube are entirely of an electrical nature, and it will be an electrician, and not a photographer, who will devise means of filtering or sifting these rays, and making their separate application possible.

To put it in photographic analogy: We want to find and reproduce the three primary colours, or any number of primary rays, whose aggregation at present we designate as X rays. Of course, the photographer will find a new field of activity through the new process; I have no doubt that every infirmary or hospital will in future require its photographic assistant, not only for the New Photography, but also for the ordinary photographic registration of cases for reference purposes, a thing that certainly ought to prove very valuable for clinical and educational purposes.

But even here the poor photographer meets already with a competitor in the shape of the fluorescent screen, or cryptoscope, or fluoroscope, a most simple piece of apparatus, which, however, has had the distinction of being invented four or five times during the last three months.

Those who followed the first scientific reports of Professor Röntgen's original discovery will remember that it was this very screen which led Professor Röntgen to his remarkable discovery, since he accidentally observed fluorescence where he did not expect it. A month after, we read most startling newspaper accounts of Professor Salveoni's discovery of the cryptoscope to make the X rays visible, we heard of various English experimenters improving upon it, and not long ago Edison himself was magnanimous enough (for the first time in his life, as he himself acknowledges) to give to the world his fluoroscope free of patents, &c. Well, all these full-sounding names denote the same thing, which I propose showing you to-night if my tube works well enough.

The screen is simply a piece of paper coated with some salt, which, under the action of the X rays, becomes fluorescent. If we interpose an object between the source of the X rays, that is, the tube and the screen,

we will get a shadow or non-fluorescent spot on the screen wherever the X rays cannot penetrate the object. It is, in fact, the same as if you take a candle in a dark room and hold between it and a ground glass an object which is partly opaque and partly transparent, you get a shadow picture on the ground glass. The lantern slide will make this clear.

The various screens, of which I have a selection here, differ only in the nature of the fluorescent salts.

There are about seventy-two such salts known, which are more or less suitable, but at present three are chiefly used, viz., the original platinocyanide of barium, the platinocyanide of potassium suggested by Mr. Herbert Jackson, of King's College, and the cheaper calcium tungstate recommended by Edison. The preparation of the salts and the spreading on the screen is a matter of some difficulty, and the screens are at present rather expensive. I shall now try and show its detective powers to the members in small batches, as it is necessary to come very close to the screen. Before doing so, however, I should like to end this discourse by pointing out that Professor Röntgen certainly deserves all the more credit for his discovery, because he at once made it public without in any way trying to secure pecuniary advantages from it. He thus enabled the scientific workers of all countries to take it up and to bring it to a pitch of comparative perfection within such a short time as, of course, would not have been possible had a single man, however prominent and skilled, tried to elaborate and improve it.

It would be rash at present to attempt to predict the outcome of the experimenting going on now, but it is certain to bring us an appreciable step nearer to the ultimate solution of the nature and composition of all matter and the fundamental law governing all existence.

Further donations are most earnestly requested, and will be thankfully acknowledged by

Fredk. H. Varley, 82, *Newington Green-road, London, N.*

Our Editorial Table.

Marion's Adhesive Film-holder.

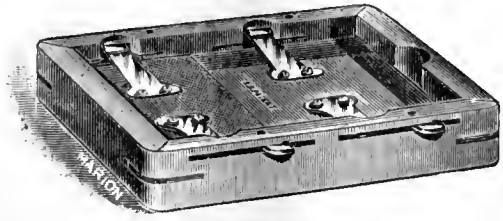
Marion & Co., Soho-square, W.

Users of cut films, among whom we not infrequently count ourselves, will welcome these film-holders which consist of thin sheets of ebonite, coated with a substance that retains its adhesive properties unimpaired for many months. The films readily adhere, and are as readily detachable.

A New Printing Frame.

Marion & Co., Soho-square, W.

The advantages claimed for this printing frame are that it is neat; occupies a small space; that the fixing of the back in position is done by means of a downward movement only, thus obviating any possibility of displacing the print, and that evenness of pressure over the whole of the plate and quickness of working are also obtained.



The back of the printing frame is released by four small spring catches shown in the illustration, and the back itself, being unequally divided, allows of rather more than half the print being examined when occasion demands. It is a capital frame, and, especially for securing perfection of contact in printing, a point not always assured with ordinary printing frames, should be found very useful.

The Wellington Film Varnish.

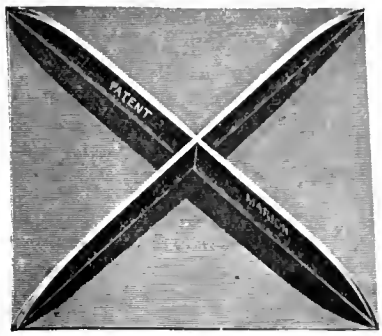
Wellington & Ward, Elstree, Herts.

An excellent varnish for films is being sent out by Messrs. Wellington & Ward. It requires no heating. For use, sufficient varnish is poured into a flat porcelain dish, and a single film immersed therein. It should then be raised by very slowly lifting from the solution, and pinned up by one corner to dry. The varnish is primarily intended for use with the Wellington film, to which we have already referred.

Marion's "Plate Separator."

Marion & Co., Soho-square, W.

This is a simple contrivance, designed to prevent plates damaging one another when two or more are being developed in the same dish. The corner of the plate is placed in the corner of the separator, which is apparently made of celluloid, and cannot then slip over its neighbour and damage the film. To the hand-camera worker,



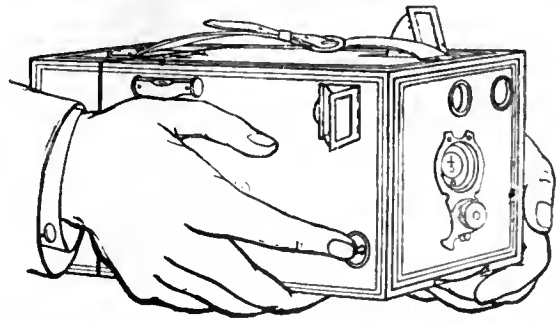
especially, with numbers of plates to develop, and to photographers generally, these handy little separators should be a comfort in working.

They may be obtained to accommodate two or four plates; the illustration shows one made to take the larger number.

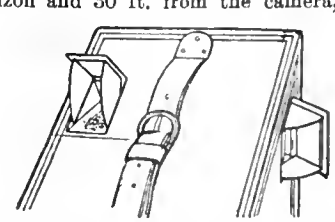
The No. 3 (5×4) Frena.

R. & J. Beck, 68, Cornhill.

Messrs. Beck are introducing a 5 × 4 Frena which is slightly more bulky, and somewhat heavier, than the quarter-plate size, but is in other respects very much on the same model. The following is a description of the instrument:—The finders are decidedly larger, and the Frena magnifiers for photographing near objects are an integral portion of the camera. Below the front board of the camera is a revolving disc of ebonite, which has five cells and one blank space; four of these cells carry the four Frena magnifiers, and one of them



is an empty aperture. The edge of the blank magnifier disc projects slightly from the bottom of the front board of the Frena, and by this edge it may be revolved so that each of the cells may be respectively brought in front of the lens. To close the camera, the blank space of ebonite is brought in front of the lens. By revolving it until the first click is felt, the empty cell is brought into position, and the lens of the camera is opened; when this it done, it will be noticed that the uncovered edge of the disc at the bottom of the camera has engraved upon it "distance to 30 ft.," indicating that the camera as used in this state will give sharply defined pictures of all objects between the horizon and 30 ft. from the camera, with the normal



aperture of the lens *f*-11. Upon revolving the disc to the next click, the first Frena magnifier is brought into position, and the engraving on the exposed edge of the disc reads 30 ft. to 12 ft.: objects situated at this distance from the front of the camera will now be in focus.

The second magnifier gives objects sharp between 12 ft. and 6½ ft.; the third magnifier, those between 5½ ft. and 4½ ft.; and the fourth, those between 4 ft. and 3½ ft. Thus the camera can be set to the right focus, according to the objects which it is required to photograph, by the revolution of this ebonite disc, which also by a further revolution closes the camera entirely.

It will be seen from the description that a high degree of adaptability to the varied requirements of the hand-camera worker has been attained with the No. 3 Frena, which we have no doubt will be much appreciated.

Tyree's Litmus Pencil.

Thos. Christy & Co., 25, Lime-street, E.C.

This convenient tester has the appearance of an ordinary pencil, in which chemically pure blue and red litmus are inserted. It is stated to be characterised by such extreme sensibility that it will detect one part in a hundred thousand (100,000), whereas litmus paper can only detect one part in fourteen hundred (1400). For use it is directed to sharpen the ends as one would any ordinary lead

pencil, mark on a strip of white paper and insert the paper in the specimen to be tested. If the blue changes to red, acid exists; if the red turns blue, alkali is discovered. The ends should be dampened when in use. It is a handy and economic device, which all those who have to do with chemical reactions will appreciate.

The Sylvio Paper.

Wellington & Ward, Elstree, Herts.

Messrs. Wellington & Ward send us samples of their most recent make of the "Sylvio" gelatino-chloride paper, of which it is only just to say that its continued excellence and carefulness of manufacture entitle it to a front place among print-out papers. We note that the phosphate toning bath is recommended. This, a favourite bath with ourselves, gives tones of a peculiarly rich plum-coloured hue. Here is the formula for those who are disposed to try it:—

Phosphate of soda	40 grains.
Gold chloride	2 „
Water	16 ounces.

The bath should be used as soon as it is mixed.

The Perfect Developing Dish.

Marion & Co., Soho-square.

This dish is constructed with a well into which the plate fits exactly, the depth coinciding with the average thickness of plates in general use. Around the sides of the well is a narrow rabbet, the top of which is flush with the top, or film side, of the plate. At one end of the rabbet is a semicircular depression to facilitate the easy removal of the developed plate.

Among the advantages claimed by the foregoing arrangement are these:—

An easy uninterrupted flow of the developing solution, economy of solution, evenness of development. The Perfect developing dish has evidently been devised by one keenly alive to niceties of convenience in handling plates during development. It embodies some happy ideas.

Received: *Fallowfield's Remembrancer* for May. Replete with particulars of the newest introductions upon the photographic market, a perusal of Mr. Fallowfield's ever-welcome *Remembrancer* is calculated to be a source of pleasure and profit to the photographer.

News and Notes.

Royal Photographic Society. — Photo-mechanical Meeting, Tuesday, May 19, at 12, Hanover-square, at eight p.m. *Photo-mechanical Methods in Austria*, by Ignatz Herbst.

The Photographic Club.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, May 20. Mr. R. Child Bayley will read a paper entitled *Photographic Societies and Photographic Art*. Visitors will be welcome.

Mr. Edison is reported to have said to a press representative that he discovers "a great many things that I would be glad to give to the public for nothing, but I dare not. I have to patent these things to save myself from defending law suits. There are a lot of sharks in this world who are continually on the look-out for new things, and, when one of them hears of something new, he bustles to the Patent Office to see if it is patented. If it is not, he claims it as an original discovery, and files his claim." Then, it appears, law suits follow, and all this in spite of the fact that the United States maintains a large staff of examiners in the Patent Office.

Derby Corporation Exhibition of Photographs.—This Exhibition, to be held in the Art Gallery, Derby, will open about July 1, and remain open ten weeks, and works will be received at the Art Gallery on Monday, Tuesday, and Wednesday, June 22, 23, and 24. The Committee will award gold, silver, and bronze medals for the best works exhibited in the various classes. Jurors will be appointed to make the awards, and the Committee reserve to themselves the right to withhold any of the medals offered if, in the opinion of the Jurors, there are no works of sufficient merit in any class to warrant their being given. In connexion with this Exhibition there will be a display of works produced by processes dependent upon and akin to photography. All works must be sent, carriage paid, addressed to Mr. W. Crowther, Art Gallery, Derby, of whom entry forms and all further particulars may be obtained. The following medals will be awarded:—Two gold medals, one for portraits, groups, or *genre* pictures; one for landscapes, architecture, or any subject not coming under the above classification. Silver and bronze medals in each of the following classes: C, Landscape, Seascape, or series of; A, *Genre* or Figure Pictures, or series of; D, Architecture (interior and exterior), or series of; B, Portrait, or series of (not more than six frames); E, Instantaneous Pictures, or any other Pictures of special merit not included in the above classes, according to the discretion of the Judges. The Exhibition will not include lantern slides.

The Sixth Annual Exhibition of the Wolverhampton Photographic Society was held on Tuesday evening, May 5, in the Assembly-room of the Wolverhampton Blind Institute, Victoria-street, a large company being present. The Exhibition was regarded as satisfactory, the number of photographs exhibited numbering 138, besides nearly fifty photographic lantern slides. The standard of excellence observed in former years was fully maintained. The Exhibition was divided into six sections, and certificates of merit were awarded to the best productions in each section, the Judges being Dr. Hall-Edwards and Mr. E. C. Middleton, of Birmingham. In the section devoted to Landscapes and Seascapes, certificates were awarded to Mr. H. E. Perry, for the photograph *Waiting;* to Mr. J. Gale, for *The Evening Hour;* and Mr. G. Hanmer, for *A Lane at Chesterton*. In the Architecture Section, awards were secured by Mr. J. Gale, for *Stokesay Castle;* Mr. H. E. Perry, for *Newark Castle;* and Mr. J. Stokes for a view in Aston Hall. Mr. H. E. Perry was successful in the Hand-camera Section with two views, *Inward and Outward Bound* and *Norfolk Natives;* in the Enlargements Section, with a view of *The Angel Choir* of Lincoln Cathedral; and in the section devoted to Animal and Flower Photographs, with the picture *Animal Courtesy*. In the course of the evening the lantern slides were illuminated and shown upon the screen, Mr. Gale acting as lanternist. After the Exhibition, awards were made to Mr. J. Gale and Mr. H. Holcroft, each for a set of three views. At the close a vote of thanks was accorded the Judges on the motion of Mr. H. E. Perry, seconded by Mr. H. Holcroft. In reply, Dr. Edwards said that the lantern photographs were exceptionally good, and might be exhibited with success anywhere.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
18.....	North Middlesex	*Intensification and Reduction.* W. Taylor.
18.....	South London	*Successful Portraiture.* Nahum Luboshez.
19.....	Birmingham Photo. Society ..	*The Choice of a Subject.* W. S. Herton.
19.....	Brixton and Clapham	Ordinary Meeting.
19.....	Gospel Oak	*Composition.* C. Stone.
19.....	Hackney	*A Chat about Advantages of Carbon for Making Enlargements.* J. A. Sinclair.
19.....	Leeds Photo. Society	*Platinum Printing.* T. W. Thornton.
19.....	North Surrey	Hints on What to Do and What Not to Do in the Field during the Holidays.
19.....	Royal Photographic Society ...	*Photo-mechanical Methods in Austria.* Ignatz Herbst.
20.....	Borough Polytechnic	*Photo Chemistry.* J. D. Evans.
20.....	Croydon Camera Club	*A Talk about Successful Portraiture and Bromide Papers.* Mr. Luboshez.
20.....	Photographic Club	*Photographic Societies and Photographic Art.* R. Child Bayley.
21.....	Ashton-under-Lyne.....	General Meeting to Receive Reports of the Rambles and to Compare Results.
21.....	West Surrey	*Clouds and Cloud Negatives.* G. H. James.
23.....	Borough Polytechnic	Excursion: Richmond Park.
23-25	South London	Excursion: Brockenhurst and New Forest District. Leaders, C. H. Oakden and A. E. Allen.

ROYAL PHOTOGRAPHIC SOCIETY.

May 12.—Ordinary Meeting,—the Earl of Crawford, K.T. (Vice-President), in the chair.

Election of Judges.

The Hon. Secretary announced that the following gentlemen had been elected to act as Judges at the forthcoming Exhibition, viz., *Art:* Mr. F. P.

Cembrano; Colonel Gale; Mr. B. W. Leader, A.R.A.; Mr. G. A. Storey, A.R.A.; and Mr. W. L. Wyllie, A.R.A. *Technical:* Captain W. de W. Abney, C.B., R.E., &c.; Mr. Chapman Jones, F.I.C., F.C.S.; and Mr. Andrew Pringle, F.R.M.S.

Mr. J. B. B. WELLINGTON read a paper upon the subject of his

NEW STRIPPING FILM,

demonstrating the operation of stripping, and exhibiting specimens of the film in the various stages of manipulation, which were fully described in our issue of May 1, page 284.

Mr. ALFRED WATKINS read some notes on

THE PYRO-DEVELOPED IMAGE.

Starting with the fact that a pyro-developed image is warmer in colour than that produced by other developers, and that the colour is dependent to a considerable extent upon the presence or absence of sodium sulphite in the developer, he said that, when all the silver was removed from such a negative, a yellow-brown image was left, varying in intensity with the gradations of the exposure, indicating that the stain was not caused by any action of the reducing agent. Comparative experiments in pyro development, with and without sulphite, the results of which were illustrated by means of lantern slides, showed that an equal intensity of the no-sulphite negative contained less silver and more pyro image than the negative developed with sulphite, and that the yellow image seemed to follow the same law as the silver image in respect of the relation between intensity, exposure, and development. When negatives developed with hydroquinone, rodinal, amidol, ferrous oxalate, eikonogen, or metol, were reduced with cupric bromide and hype, clear gelatine only was left, but pyro metol gave the characteristic yellow image, which was exceedingly permanent, for unsuccessful attempts had been made to reduce it by means of acid alum, thiocarbamide, and other agents. Another slide showed that the black silver image obtained by development with metol, superposed upon the yellow pyro image, reproduced the character of the original pyro-developed negative, pointing to the conclusion that the latter was formed of two constituents, the black silver deposit and the yellow pyro image. The presence of free bromine and pyro seemed necessary to the formation of the latter, and, when sufficient sulphite was present in the developer to absorb the bromine as liberated, it was not formed. With most printing papers, the yellow image appeared to give softer gradations than a black image of equal intensity in the high lights. Mr. Watkins thought the slight yellow stain, caused in the film by development with pyro, was quite distinct from the yellow image before referred to; it was to some extent removable by clearing agents, and was deposited on exposed and unexposed parts alike. He had found that long washing before fixing was a cause rather than a preventive, of this yellow stain. The gradations of the yellow image could not be accurately estimated by the shadow photometer, as used in the Hurter & Driffield system, and he thought that negatives developed to give the black silver image only would be best suited for determining the H. & D. numbers of plates.

Mr. J. SPILLER said that, the larger the quantity of alkali present in a pyro developer, the less was the tendency to stain. It was easy to remove the stain by washing with an alkali, and by treating a deeply stained pyro-developed negative with a solution of washing soda, he had completely changed its character, for it was rendered as transparent and steely as one developed with metol or eikonogen.

After some discussion,

Mr. H. SNOWDEN WARD read a paper on

DRY PLATES FOR RADIOGRAPHY,

detailing experiments with seventeen varieties of plates, the duration of the exposures varying from one to four minutes with a two to three-inch spark, development being by means of a standard ferrous-oxalate developer at 60° Fahr. With regard to the correspondence between light sensitiveness and X ray sensitiveness, it appeared that plates fairly sensitive to daylight were needed for radiography, but some curious observations were made; for instance, a plate which read about 130 H. & D. gave immensely better results than plates by the same makers reading 158 and 331. A plate specially prepared for radiography gave a very dense deposit of silver all over, even under a safety strip of copper and lead. Dr. Hesekiel had exposed a dry plate beneath a packet of a dozen sheets of bromide paper, obtaining good images alike on plate and papers, which seemed to suggest that speed would be increased in direct proportion to thickness of coating. Experiments with one make of plate confirmed this idea: but, with a different plate, the result was quite opposite, though this was probably due to an error on the part of the plate-maker with regard to the double coating. Soaking the plates in solutions of fluorescent salts tended rather to loss of sensitiveness than to increase of speed, and celluloid apparently had no advantage over glass as a support for the sensitive film. The results of a large series of tests were shown by means of tables of comparative readings, indicating, among other points, that, with a suitable film, increase of thickness was a decided advantage, and that the amount of silver present was an important factor.

In reply to questions, Mr. Ward gave some details as to the precautions taken in his experiments to ensure accuracy of result, and the meeting concluded with the passing of a vote of thanks to him, similar compliments having already been paid to Messrs. Wellington and Watkins.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 7.—Mr. A. L. Henderson in the chair.

The HON. SECRETARY had been going into the question of the effect of colour in the glass of which lenses are made at the present time. There were some rather yellowish-coloured glasses used in lenses now, and he thought they might have very material influence on the rapidity of these lenses. As a rough, but imperfect, test, he took five different lenses, and placed them upon a piece of printing-out paper in the shadow of a wall for about twenty minutes. The lenses included a Goerz, a Steinheil aplanat, a new single Zeiss lens, a Concentric, and one of Swift's, and were all at their full apertures. He passed round the print, with the images of varying intensities, remarking that he thought the subject worthy of further and a more critical investigation. His object was to test the absorption of different specimens of glass, so as to obtain some sort of factor.

The CHAIRMAN suggested, as an improvement, the removal of the lenses from their mounts, with the use of a ground-glass cover to counteract any chance interference by clouds, &c. He recollected an American exhibiting a number of examples of the effect of light upon glass which was considerable.

The HON. SECRETARY read a letter, received from the Gospel Oak Photographic Society, asking for the Association's co-operation in their protest against the so-called improvements being made by the London County Council on Hampstead Heath. He thought the London and Provincial should give their support in time to prevent its rural appearance being spoiled.

Mr. WELFORD agreed, and proposed that the Gospel Oak Photographic Society be informed that the London and Provincial accord their warmest support in preserving the beauties of the Heath, and asking in what manner their help would be appreciated.

Mr. FRESHWATER seconded the motion, and it was carried.

Mr. Freshwater gave a verbal description of Mr. Friese Greene's new apparatus for rapid photographic printing for book illustration, by which about 2000 prints per hour can be obtained.

THE AFFILIATION SCHEME.

The HON. SECRETARY, as one of the delegates of the Association to the Committee of the Affiliation of Photographic Societies with the Royal Photographic Society, read a report on the subject (see page).

Mr. W. D. WELFORD thought that, as the matter stood at present, the Royal Photographic Society left it to the societies themselves to suggest means of improving and carrying on the scheme, a work which should be done by itself, and which would then bring them the support required. He was of opinion that the Royal Photographic Society would not be at all sorry if the Affiliation was upset.

Mr. R. P. DRAGE inquired whether the Secretary had attempted to find out the views at present held by the Council of the Society in the matter. He considered it would be a pity for the Association, one of the original founders and supporters of the scheme, to be the first to wish to discontinue its support.

The HON. SECRETARY argued, however, that, if the Affiliation was likely to be of use, it should have made more headway during a trial of four years. The results of the first two years were, no doubt, fairly good; but since then it had got weaker and weaker, showing there was no more interest taken in the movement, and he was convinced that it had lost its utility and was on its last legs. The support of the Royal Photographic Society might have rendered its existence more productive, and, having stipulated for so much control in the management, it had neglected its duty sadly.

Mr. WELFORD said that the fact that it wanted so much control would show that the original intention of the Society was to support it as much as possible, but he agreed that it had failed to do so.

After further discussion, Mr. DRAGE proposed that the Association continue its support for one more year. This was seconded and put to the meeting, and was carried by seven to three.

PHOTOGRAPHIC CLUB.

MAY 6,—Mr. Isenthal in the chair.

It was pointed out that the statement in the minutes of a previous meeting, that Mr. Isenthal's Rhumkorff coil was actuated by a primary battery, was an error. Storage cells were used for the purpose. The two whole-plate negatives made at the X ray demonstration by Mr. Isenthal were passed round.

The SECRETARY read a note from Mr. Bedding, expressing his regret that he could not give his paper as arranged, and adding that he hoped to redeem his promise on some future occasion.

Mr. J. A. Sinclair passed round some carbon prints by Artigue's method. The characteristic feature of the prints, which were of great excellence, was a fine rendering of the half-tones, accompanied by considerable pluck and brilliancy. Mr. Sinclair's method is to sensitise the Artigue tissue in a two per cent. bichromate bath for two minutes; when dry (the drying does not take long), the tissue is ready for printing. This takes about the same length of time as does ordinary carbon tissue, but it is a characteristic feature of the process that there is no continuing action. Mr. Sinclair develops his prints by placing them in warm water at a temperature of 85° to 90° Fahr., until the image begins to appear as a silhouette. He then places the tissue in colder water, temperature of about 60°, and resorts to the sawdust-soup method of development. The sawdust is of the size of fine sand, and can be used over and over again. Mr. SINCLAIR stated that he now used the same sawdust soup as he had done when he began to work the process. By means of the sawdust and water the print can be locally developed. Generally speaking, prints made by this method yield more vigorous results than do either ordinary carbon or platinum.

A general discussion ensued upon the process, there being a consensus of opinion that the results were very fine indeed, and that the process would afford an opportunity for such as were skilful and careful workers rather than for such as desired a more simple method.

Mr. Nesbitt passed round a small album containing prints from the exposures he had made with an Eastman guinea camera in Paris at Eastertide.

The Club's special summer excursion was fixed for Saturday, June 27. Further particulars will be announced.

Mr. Child Bayley's paper on the 20th will be entitled *Photographic Societies and Photographic Art.*

Brixton and Clapham Camera Club.—May 5, Mr. J. W. Coade (President) in the chair.—A lantern lecture on

INDIA AND BURMA

was given by Dr. CUTHBERT WYMAN, of the Putney Photographic Society. This gentleman's slides were of exceptional interest, and gave one a vivid conception of that part of the globe in regard to its scenery, architecture, and native characteristics, the frequent applause evidencing the appreciation of a good thing by the audience. The subject for next meeting (May 19) is *Enlarged Paper Negatives*, and is by Mr. H. Stuart, of the North Middlesex Photographic Society.

Hackney Photographic Society.—May 5, Annual General Meeting.—The Society's balance-sheet and report showed a very satisfactory state of affairs. The members heard with regret that Mr. W. Fenton-Jones did not seek re-election to the office of Hon. Secretary, on account of pressure of business. However, no one being willing to take his place, he was persuaded to resume the duties for at least one year longer. Mr. H. Rose also sought retirement from the post of Hon. Lanternist, but he consented to act again *pro tem.* As a result of the election, the new Council is as follows:—*President:* Mr. Thomas Bedding, F.R.P.S.—*Council:* Messrs. L. S. Wilks, F. Gosling, W. Rawlings, F. Houghton, A. Barker, E. Puttock, Dr. Roland Smith, and Major C. Woolmer Williams.—*Hon. Lanternist:* Mr. A. Rose.—*Hon. Treasurer:* Mr. J. O. Grant.—*Hon. Secretary:* Mr. W. F. Fenton-Jones.—*Hon. Assistant Secretary:* Mr. A. D. Fort.—*Hon. Excursion Secretary and Curator:* Mr. A. Dean.

ON May 7, a very successful lecture and demonstration of the X rays was given by Mr. J. E. GREENHILL, at the Morley Hall, to a large audience. In the course of the lecture Mr. Greenhill took a number of radiographs of various objects, and the plates were developed, lantern slides reduced from the negatives by Dr. Roland Smith and Mr. Rawlings, and shown on the screen at the close of the lecture.

South London Photographic Society.—May 4, Mr. F. W. Edwards in the chair.—Mr. W. THOMAS, Chairman of the Affiliation Committee, gave an address on

PICTORIAL WORK WITH THE HAND CAMERA.

He said that hand-camera work had been despised and looked down upon by certain persons, but he himself believed that pictorial records could be obtained with the hand camera, and the best test of the sincerity of the belief was the practising of it. Misconception exists as to what are the necessary fixtures. The first is a good lens, of not too short a focus (five inches or five and a half inches) on a quarter-plate. The larger the available working aperture the better. He had one which could be used at 5·6, if necessary. Two fairly large finders will be found to be important features and have considerable bearing upon the results. They should include as much of the view as the lens does on the plate; if they include more, that portion should be stopped, but by the use of black paper or black varnish. The shutter should have means to vary the speed; the one he used (Thornton-Pickard) he considered too fast, as it could not be set at less than one-fifteenth of a second without setting it for time exposures. The use of plates or films is a mere detail of convenience. Mr. Thomas followed by making some remarks on the composition of pictures, illustrated by diagrams, and explained some of the rules underlying the composition of pictures which he brought with him. In answer to questions, it transpired that the lenses used by the lecturer were Wray's and Taylor, Taylor, & Hobson's, and his favourite plates were Lumière's Series A. In replying to the vote of thanks, he said the three important points he should like to leave behind were: (1) that it was advisable to strive for perfection in technique, and then to use it wisely; (2) mere material for subject is of minor importance, success in the treatment of it is the measure of success; and (3) in every pictorial effect very little detail is necessary. Mr. G. H. CRICKS showed and explained, on behalf of Messrs. W. H. Whittingham & Co., a large number of hand cameras. The arrangements for the three days' outing to the New Forest, at Whitsuntide, were discussed.

Carlisle and County Amateur Photographic Society.—The Eleventh Annual General Meeting of this Society was held in the Viaduct Hotel, Carlisle, on Wednesday, May 6. Mr. William Wright was voted to the chair, and there was a fair attendance. The Hon. Treasurer, Mr. John Robson, presented the financial statement for the year, which showed that over 15*l.* stood to the credit of the Society. The meetings of the winter session have been fairly well attended, and included lantern exhibitions of the following:—Set of slides by Mr. Paul Lange, prize slides, also an exhibition of members' slides at last ordinary meeting. A long and animated discussion ensued with reference to an extension of the Society's usefulness to the younger members, whereupon it was resolved—"That a room should be obtained for five winter months; that the Society should meet once a fortnight; that demonstrations of processes be given; and that there be papers and discussion upon photographic matters, in addition to the annual lantern meetings." It was decided that print and lantern-slide competitions be held amongst the members. The following gentlemen were elected office-bearers for 1896-7:—*President:* The Mayor of Carlisle.—*Vice-Presidents:* Messrs. R. Maclaren, M.P., and Warwick Hele.—*Committee:* Messrs. J. Beaty, J. Forsyth, R. M. Hill, W. Milburn, and W. Wright.—*Hon. Secretary:* Mr. J. S. Atkinson.—*Hon. Assistant Secretary:* Mr. Samuel W. B. Jack, 7, Petteril Bridge-terrace.

Edinburgh Photographic Society.—May 6.—The Edinburgh Photographic Society had under discussion

THE HAND CAMERA.

The subject was introduced by Mr. C. FRASER, and Mr. J. C. Oliphant, M.A., presided. Some fourteen kinds of hand cameras were shown by different members, the pocket Kodak being the smallest, and a half-plate camera the largest. Most of the members seemed to prefer plates for snap-shot work, but some of the best workers advocated the use of films, Mr. F. P. Moffat and Mr. James Patrick (Vice-Presidents) both speaking favourably of the latter. In speaking about films, Mr. PATRICK strongly deprecated the habit which some workers have of developing a large number at once. One at a time, he said, was all that could be undertaken if perfect results were hoped for. He mentioned the case of a gentleman who was in the habit of putting a number of films into a large dish of developer, and giving the whole an occasional stir with a stick. This worker *might* get one or two passable negatives out of the lot.

APRIL 13.—A joint meeting of the Royal Scottish Society of Arts with the Edinburgh Photographic Society was held in the hall of the former Society, in George-street, when Mr. F. E. IVES delivered his lecture on the

PHOTOCHROMOSCOPE.

There was a large audience, and the chair was occupied by Professor Armstrong, President of the Society of Arts. Mr. Ives was heartily thanked at the close of the lecture.

Photographic Society of Ireland.—May 8, Professor J. A. Scott (President) in the chair.—Subjects,

ODDS AND ENDS,

by Mr. J. H. GANE;

THE ZEISS AND TAYLOR LENSES,

by Professor SCOTT. *Odds and Ends* consisted in the demonstration of lantern slides, with description of various subjects taken during the season by Mr. J. H. Gane, and which comprised chiefly sea pictures and yachting studies, some of which were certainly of the highest order. Mr. Gane's works showed careful treatment, and were marked with a good deal of observation of subjects which lent themselves to pictorial effect. His efforts were received by the audience with merited applause. Professor Scott described very lucidly, and in an interesting way, a difficult subject for the popular taste. The Professor explained and showed by diagrams and various photographs the results produced by astigmatic lenses, and compared them with those done by the Goerz, the Zeiss, and the Cooke lenses, of which he gave lengthened descriptions of their structure, and showed the degree of freedom from astigmatic defects. He thought the Cooke lens, while producing results equal to the foreign makers, had the advantage of being very much less costly. At the conclusion of the evening, a test was made with the oxyhydrogen light against the oxyl-ether jet; the former proved the brighter of the two, while the latter was a quieter light, colder in colour and less hurtful to the eyes.

Patent News.

THE following applications for Patents were made between April 29 and May 6, 1896:—

FRAMES.—No. 8804. "Improvements in and relating to Frames for Holding and Displaying Photographs and the like." R. B. MILLER.

COLOUR PHOTOGRAPHY.—No. 8865. "Improvements in Colour Photographs and Apparatuse for use therein." B. J. EDWARDS.

VIEW-FINDER.—No. 9139. "An Improved Photographic View-finder." S. J. LEVI and A. J. JONES.

HAND CAMERAS.—No. 9309. "Improvements in Hand Cameras." S. HEBBLEWHITE.

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

REPRODUCTION OF DIFFRACTION GRATINGS.

To the EDITORS.

GENTLEMEN,—From the report of the Camera Club Conference, I see that the discussion of the difficulty that I had met with in removing the turpentine after development of a bitumen grating has obscured the fact that I have done many successful copies (one was handed round) by this process, with one not only much more brilliant than the original, but brighter than copies by any other process. The difficulty referred to is serious only when the development is pushed. Otherwise the turpentine can be removed without trouble, either by washing with water or by centrifugal force.—I am, yours, &c.,

RAYLEIGH.

10, *Downing-street, Whitehall, S.W., May* 6, 1896.

FINDERS.

To the EDITORS.

GENTLEMEN,—I read with some surprise, in your issue of April 17, that a patent has been taken out by Mr. G. F. Fraas for view-finders consisting of a variety of combinations of prisms and lenses, or of plane and curved surfaces in prisms. I do not see how a combination of an ordinary lens and a prism would have any advantage over a lens with an inclined mirror, and it would be much more expensive; but the combination of curved and plane surfaces in a prism has been used for finders in our hand cameras for some time, our first finders of that sort having been made something like two years ago. We have now on hand, in various stages of manufacture, more than a thousand finders, consisting of prisms with one face formed into a convex lens; and, although we no longer use them in our hand cameras, for the reason that the variation of the image in the finder with the position of the head makes it difficult to arrange the picture accurately with them, we certainly do not propose to abandon our

prior rights in connexion with them. Besides the prisms with convex surface, we have experimented with a prism with concave surface, which also makes a brilliant finder, with some curious properties.—I am, yours, &c.,

T. M. CLARK, *Treasurer.*

The Technical Company, 22, *Congress-street*, *Boston*, *April* 28, 1896.

ASSISTANTS AND THEIR GRIEVANCES.

To the EDITORS.

GENTLEMEN,—With reference to previous correspondence concerning assistants and their grievances, it seems that operators and assistants, &c., have grown stronger on the subject of a union; innumerable schemes have been put forth with a view to improving their lot, but little reform has been effected. The reason for these repeated failures is not far to seek. Many assistants have failed to grasp the important fact that a union is necessary, and, until they do, it will be impossible to do away with existing grievances.

Of the many letters which I have read in the JOURNAL, not one has a word to say concerning the treatment meted out to the reception-room young ladies, employed by a firm of cheap photographers (this firm is, I should say, indicated by a retoucher of thirty years' standing), who suffer under the same grievances as the operators and retouchers; receive 12*s.* per week, for which they work from 9 till 8, with hardly any time for meals. They also work on all bank holidays, and are bullied should they not "table sitters" well. Should the takings, at the end of the day, be short, they are required to make up the same out of their hard-earned wages.

At one studio where I was retouching, a parcel was delivered, addressed to the head of the firm, with 1*l.* to pay. The money was paid, and, when the head arrived and opened the parcel, it was found to contain a brick. The operator, a "mere lad," was bullied and told he would have to refund the sovereign, which he did. This operator was receiving 25*s.* per week. The majority of assistants employed by this firm are mere puppets in the hands of the head of the firm. In other firms, assistants work in the most friendly and cordial relations. Why not in this firm? It is also a well-known fact that they work their hands till illness overtake them, and are compelled to lay up, when they are stopped for same.

With regard to the Union, I am afraid it will be rather uphill work to get together 20*l.* the sum suggested by Mr. Randall to start a Union with, unless some kind friend comes forward with that amount. I have not the least doubt that once a Union is started it would be a great success; but, failing this, I hasten to join in the excellent suggestion made by Mr. Randall, that assistants should join the Shop Assistants' Union, when they could, by every legitimate means, endeavour to secure that justice which hitherto has been denied them.

I would commend to all workers, specially those employed by this sweating firm, of which so much has been heard of late, to the above Union, whose objects seem to cover all their grievances. The subscription is small, and it now remains for all workers to join in large numbers.

I am sure the best thanks are due to Mr. Randall, who has so eloquently pleaded their cause in the correspondence columns of the JOURNAL, and who is now devoting himself to the redressing of their grievances, and to this end he should secure the co-operation of all workers in this profession.

One word in conclusion. All *employés* of the cheap firm must have hailed with intense satisfaction the letters which you have so kindly published from time, and I thank you most sincerely and cordially for the assistance you have always given to operators and assistants generally to make known their grievances.—I am, yours, &c.,

J. W.

London, *May* 9, 1896.

To the EDITORS.

GENTLEMEN,—Since my letter which appeared in a recent number of the JOURNAL, I have received a communication from the friends of "L. C.," putting me in possession of the facts of the case and the identity of her employer. After considering these particulars, I am surprised at the mildness and the moderation of language with which Julia Dawson stated the case of "L. C." in the *Clarion*.

I believe it would not be possible to find in our industrial system another instance of such abuse of power, of absolutely unnecessary interference with *employés* by meddlesome regulations, of grinding down of wages, forcing the recipients to the verge of crime, of unhealthy and unsanitary conditions, of total want of consideration, of delight in inflicting pain upon *employés* out of mere wantonness, of a spirit of vindictiveness and of a spitefulness which passes belief. Harsh treatment and sharp practices might be expected from an employer engaged in running a business which depends on cutting prices, and who makes his profits out of the ruin and bankruptcy of his fellow-employers; but, in this case, even this extenuating circumstance is wanting.

"L. C." is employed by a leading lady photographer, who charges for her work a sum nearer three guineas than five shillings a dozen. Her patrons come from amongst the wealthiest and the highest in the land, her praises are sung by many fashionable journals, and her work is reproduced week by week in the pages of the leading illustrated papers. This lady, when not otherwise engaged, occupies her time in interviewing journalists, airing her views on the emancipation of women, and informing all and sundry about the two and three guineas per week she is paying in wages to the women who are fortunate enough to be in her employ. This, however, is only her fun; these fabulous wages are purely mythical; the plain matter of fact is she pays none more than a pound, and out of very many spotters the average pay is a paltry 12*s.* per week.

Can any one come forward and assert that 12*s.* per week is a living wage? Every one knows perfectly well it is not a living, but a starvation, wage. A good spotter is worth at the least 15*s.* per week, and only last week an advertisement appeared in this JOURNAL offering 16*s.* per week for a spotter, and that *to commence!* It would be idle to urge that these girls are incompetent, and not worth more than they receive, because I know for a fact that they would not be in the place a single day if they were not up to their work.

Three shillings per week added to the wages of these girls would mean an enormous difference to them, yet, for a miserable 3*l.* 15*s.* out of a weekly profit of 100*l.*, this model employer, who is supposed to be doing so much for her sex, does not hesitate to inflict a starvation wage, and the consequent intolerable suffering upon her less fortunate sisters who are within her power. She also adds insult to injury by loudly proclaiming to the world what large salaries she pays to her *employés*, creating the impression that a spotter in her establishment receives a larger salary than an operator in the studios of the common or garden photographer.

Insult and cruelty are much harder to bear than low wages, and in the case of "L. C.," as in nearly all cases of dissatisfaction, the former and not the latter is the primary source of complaint. The rule against talking, which is here enforced, is as stupid as it is overdone. Surely it would not be very difficult to draw the line between incessant chattering and absolute silence. Other employers can do it, and why not the employer of "L. C.?"

This "system of slavery," to quote the fearless Julia Dawson, cannot possibly last if a business is to prosper. The employer who is the enemy of his workpeople will find, sooner or later, that it is a policy that fails, even from a commercial point of view, and carries with it the elements of its own destruction. Unfortunately, the actions of an individual reflect upon the whole profession, and I trust photographers, for the credit of their craft, will come forward and give an emphatic declaration that these actions do not receive their approval.—I am, yours, &c.,

18, *Canbury Park-road*, *Kingston-on-Thames*. JOHN A. RANDALL.

To the EDITORS.

GENTLEMEN,—My attention has been directed to a letter by John A. Randall, which appeared in your last issue, advocating the formation of a Union of Photographic Assistants or the alternative of joining the Shop Assistants' Union.

My personal opinion is decidedly in favour of "fewer unions and more union," and, seeing that, as Mr. Randall says, the objects of a Photographic Assistants' Union would be precisely the same as ours, I certainly would advise the photographic assistants to join the National Union of Shop Assistants, Warehousemen, and Clerks, and strengthen an organization that has now got over the inevitable initial difficulties in connexion with the formation of every union.

We are now in a position to assist in paying the expenses in connexion with the formation of branches, and will be glad to communicate with any assistant desirous of seeing a branch started where there is a reasonable chance of success. I will be glad to forward a copy of our rules on application, and give any other information I can.—I am, yours, &c.,

JAS. MACPHERSON, *General Secretary.*

National Union of Shop Assistants, Warehousemen, and Clerks,
Head Office, 55 *and* 56, *Chancery-lane*, *London*, *W.C.*

THE BRADFORD PHOTOGRAPHIC SOCIETY.

To the EDITORS.

GENTLEMEN,—It grieves me to see that you have allowed your columns to become the medium of a slur being cast upon certain members of the above Society, who have done their level best to further its interests. Nobody but those closely connected with the same know to what a great extent jealousy, back-biting, and other evils have been carried on; the proceedings have been a disgrace to the Club.

A certain clique, by some means or other, got into office last year, and attempted to use the Society as a means of pushing their goods, and this year a change was planned by the so-called "opposition party" (who are real amateurs). The consequence was, the trade was thrown out, much to the disgust of the clique to which your last week's correspondent belongs. The same person reported in the local press only those reports that suited him, and, when one of the officials "with whom the Secretary cannot work in harmony" won a prize, it was, of course, not recorded; but when another prominent member wrote one, and sent it to a contemporary, he was called all the names not to be found in the Prayer-book. Another member nearly lost his position through an interfering official telling his employer that he called him (his employer, "the

boss," and numerous other mis-statements. In short, he (the *employé*) will never again be trusted. Another official (a professional) once treated an amateur demonstrator, who was giving his fellow-workers an insight into the mysteries of carbon, in a most unpleasant manner by "cornering" and other ungentlemanly exclamations.

I write this in the hope that, out of common fairness, you will give the "other side" a hearing, and not let your readers go away with the idea your last issue would give.—I am, yours, &c.,

A Disgusted Committeeman.

THE LILLE (FRANCE) EXHIBITION.

To the Editors.

Gentlemen,—Kindly permit me to call the attention of British exhibitors to the above, for which I can now supply entry forms and all information. Only works of artistic merit will be accepted, and they have to pass a Selection Committee, composed of five artist painters and two photographers. There are no awards, but each accepted exhibitor will receive a commemorative plaque or medal, engraved by M. Edgar Boubry, Director of the School of Arts, Lille. Entry forms, duly filled up and signed, must reach me on or before June 1, and the frames on or before June 10. The frames can be sent to my office, from whence they will be dispatched in a joint case or cases, and the carriage to Lille and back will be equitably proportioned. I do not, however, accept any responsibility beyond making the necessary arrangements and endeavouring to get them carried out. Exhibitors at Harlem and Paris can have their work sent on to Lille.—I am, yours, &c., Walter D. Welford.

Answers to Correspondents.

*** *All matters intended for the text portion of this* Journal, *including queries, must be addressed to* "The Editors, The British Journal of Photography," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* Henry Greenwood & Co., 2, *York-street, Covent Garden, London.*

Photographs Registered:—

E. S. Baker, 82, Bristol-street, Birmingham.—*Photograph of Aston Villa Football Club, League Champions, 1895-6.*

Alfred Ernest Harris, 44, Partridge-road, Roath, Cardiff.—*Photograph of a Mosaic of Photographs, viz., Waterfalls, Hotel, and a Portrait.*

"Cloudy;" Albert; W. R. F.; Alfred Freke; W. H. Hill, and others.—Received. In our next.

Metric Formulæ.—J. Liddy. Thanks; closer inspection will show you that it was a misprint.

Colour of Negative and its Effect in Printing.—Formula. The subject referred to was probably a discussion at the Photographic Club. If so, it will be found on page 236 of the current volume.

J. E. G. (Venice)—A somewhat difficult question to answer, but we have had the most favourable experience of Adams's and Newman & Guardia's changing backs. Shall be glad to assist you further if we can.

Photograph of Edison.—Charles Wilcox writes: "Is it possible to get a photograph in London of Mr. Edison, the inventor? Silver print preferred."—Inquire of Mr. Spooner, Strand; Messrs. Marion, Soho-square; Messrs. Mansell, Oxford-street, W.

Stains on Cloth.—A. E. Lane. Unless we knew the composition of the dye, which you have not stated, it is, of course, impossible to say what will remove the stains. Probably, however, whatever would remove the stains would also alter the colour of the cloth where the stains were.

Coarseness of Grain in Negatives.—T. Hendy. The coarseness of the grain is due to the emulsion, and not to the method of development. Some very rapid plates, such as those you have evidently been using, have a very coarse grain. As a rule, the slower plates are the finer is the grain.

Spotting Colour.—W. R. H. asks: "Can you advise me where to get a spotting colour for enamelled pictures, as the ordinary spotting colour comes off during enamelling?"—Colours for the purpose are supplied by most photographic dealers. If yours does not supply them, you can get them from Mr. Rudowsky, Guildhall-chambers, E.C.

Right to Photograph.—C. W. E. says: "There is to be a flower show and *fête* in our neighbourhood at Whitsuntide, to be held in a private park. The admission will be 1*s*. I applied to the Secretary for permission to photograph in the grounds on the day, and especially a ceremony that is to take place. He said the Committee had, for a consideration to the charity, sold the right to another photographer. Can you tell me if I pay my shilling, and another for my assistant, for admission, they can legally prevent me from taking such negatives as I choose?"—Yes, certainly, as the grounds are private property.

Enamelling Silver Prints.—T. Mathias. The cause of the collodion becoming ropy, and flowing with difficulty, after a few plates have been coated, is the evaporation of the solvents. The collodion should be thinned with ether and alcohol—say, five parts of the former to one of the latter, as the ether evaporates more quickly than the spirit.

Enlarging.—Enlarger. 1. Cover the window with one or more thicknesses of ground glass, according to the strength of the sunlight. 2. Yes, certainly, if the optical arrangements are good, as they are in the various apparatus supplied specially for the work. 3. You had better use the formula recommended by the makers of the paper you employ. What would be the best developer for one brand of bromide paper is not necessarily the best for any other.

Studio and Building Laws.—Stopped. See reply to "S. W. B." If the Town Council have served you with notice to pull down the studio, we can only assume it is within its right in doing so. Of course, you can fight the matter out in a court of law; but that will cause delay, and involve some expense if you gain, and very much more if you lose. Would it not be better to modify the structure so as to conform to the requirements of the authorities, which do not seem very much, after all, and thus save time (and the season is advancing) and cost?

Studio.—S. W. B. The design for studio shown in sketch B will be the best in every respect. Also the dimensions are good. The other part of your letter is not so easy to answer, because so much depends upon the by-laws of the district in which you reside. We may say, however, if it were in the metropolis, the building would not be allowed to be put up, of the materials proposed, in such close proximity to the house. Our suggestion is that you submit plans to the town authorities, and get their approval, before commencing the erection.

Bromide Prints for Platinum.—C. and C. S. write: "We know for a fact that a photographer here is regularly supplying his customers with bromide paper prints as platinotypes, and for which he is charging fifty per cent. extra over silver prints for them. This I can prove, as we have just engaged as a printer the man who, for the last two years, has made them, and he tells us that platinum printing has never been done in the place."—This is no uncommon thing, though it is a fraud on the customers, and can be punished as such. Any one so defrauded can institute proceedings against the photographer, and, if one does, we shall be pleased to receive a report of the case for publication.

Photo-micrography.—Laboro asks:—"Will you kindly inform me the best work on photo-micrography, English or German? I have a whole-plate long-extension camera and rapid symmetrical lens (Ross's). Could I use these for microscopic work? What would be the best microscope? The best work on mounting microscopical specimens (pathological)?"—The most modern work and best is that by Andrew Pringle, published by Iliffe & Co. The whole-plate camera may be utilised; but, if the lens be a whole-plate one, it will not be suitable. Any good microscope will answer. We know of no work specially devoted to mounting pathological specimens. In Mr. Pringle's work will be found much that is useful on the subject.

Wet-plate Bath for Printing.—Printer writes: "Kindly inform me the best way to prepare an old wet-plate bath for sensitising albumen paper (to get rid of the iodine). Does boiling down till fusion takes place get rid of all foreign matter?"—Add to the bath a solution of citric acid, say, two drachms of a thirty-grain solution to each quart of bath, then add liquor ammoniæ till the blue colour of litmus paper is restored. Filter and acidify with nitric acid. If the solution be then made up to the requisite strength with fresh nitrate of silver, it may be used direct. If the bath be evaporated and the nitrate fused, the whole of the iodide will not be got rid of, but what remains will do no harm. We have often strengthened up a collodion bath, and used it without further treatment, and found no trouble.

Commencing Business. — Studio says: "I must ask you to pardon my troubling, but I should be so very much obliged if you would give me your valuable advice on the following question: I am at present employed by a firm, but I find that the long hours and worry are simply ruining my health. I have saved about 60*l*., and thought I should open a studio for myself. I am thoroughly experienced in every branch, including operating. Do you think I have sufficient to start with in a humble way? and would you advise me as to the best district?"—In reply: We cannot advise our correspondent to start in business with such a small capital: at least double or treble would be necessary. Possibly the money would be best utilised by enabling our correspondent to take a more suitable situation and purchase a small share of the business.

Toning Difficulty.—Scotia writes: "I am a user of Ilford P.O.P. (mauve) to a considerable extent, and of late have had the same experience in discolouration as your correspondent, 'W. K. S.' I am a careful and clean worker, and am at a loss to account for it. The prints are all right when toned, and continue so if put into the hypo within, say, ten minutes after toning, but, if washed longer, begin to turn a nasty, dirty yellow colour, which increases in intensity the longer they are washed. This colour appears on both back and front of the print. The prints are washed in running water, and are not allowed to clog, and all hypo is carefully kept out of the way. I enclose print, which was toned to an ordinary purple-brown, and which assumed the black tone in the washing. I repeat that it was washed in running water, and carefully turned about, and, being in one of the first toning batches, was washing after toning quite half an hour. If it had been put into the hypo within ten minutes after toning, it would have undoubtedly been all right, which the prints in the last batch were."—The print enclosed seems to be different from that of our previous correspondent in appearance. It has all the appearance of having been exposed to a feeble actinic light during the half hour it was washing.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1881. Vol. XLIII.—MAY 22, 1896.

Contents.

EX CATHEDRÂ.

There appears at present to be very little hope of a reform in our somewhat unsatisfactory patent system. In the House of Commons recently, in reply to Sir J. Leng (Dundee), who asked a question with reference to the suggestion of Lord Justice Kay that a comptroller of patents should be appointed to deal with prior specifications and applications for patents, Mr. Ritchie said: "I am not prepared to propose the alteration of the existing practice. The subject is a thorny one, and has engaged the attention of Parliament and of the public on and off for many years. 25,053 patents were applied for in 1895, and an enormous staff would be required if the obligation of deciding on the novelty of each application was imposed on the Patent Office. I must further remind the hon. Member that the most eminent authorities differ occasionally as to whether an invention is new."

* * *

Mr. Ritchie, or his advisers, probably exaggerated the difficulties of the substitution, for the present hap-hazard patent regulations, of a method whereby official and indubitable recognition of the validity of granted patents was dispensed, as is the case in the United States and Germany. Of course, the trouble of the department would be vastly increased, and the fees would, no doubt, be calculated on a much higher scale; but the gain to invention and industry would clearly be very great by the change. But our present patent laws bring in a large profit to the department, and furnish the lawyers with plenty of work, and these reasons, in the official mind, are, we suppose, quite sufficient to justify the perpetuation of a defective system.

* * *

Under the reform suggested by Lord Justice Kay we should expect to witness a check placed on dishonesty, and a fillip given to the cultivation of genuinely inventive ideas. If we may argue upon the evidence with which photography supplies us, under a reformed system, with a staff of examining experts at the Patent Office, perhaps not a fifth of the 25,000 applications for patents annually made to the English Office would, on the face of them, be entertained. Scarcely a week passes but what provisional protection is granted for ideas which a most superficial acquaintance with photographic history demonstrates to be, as the phrase runs, "as old as the hills." The Patent Office virtually takes inventors' money without giving value in return, a practice in which Mr. Ritchie is not prepared to propose any alteration!

* * *

Some of our readers may, perhaps, be able to furnish a correspondent with a remedy for a skin trouble, which is caused in the following manner: Whenever he touches the hypo solution with his hand, small blisters appear upon his fingers; they break and remain sore for several days, causing great irritation, besides keeping him (he is a professional photographer) from fixing operations until they are healed. We are not aware of having before heard or read of our old friend "hypo" coming under suspicion in this disagreeable manner.

* * *

Are gelatine dry plates fluorescent? If they are, then a new and valuable light is possibly thrown on the photographic phenomena of what we are still justified in calling the X rays. Mr. W. J. Wilson, of the Paget Prize Plate Company, has been good enough to hand us a number of communications to his Company from Mr. W. J. D. Walker, of Boyne Mill, Drogheda, who has found that the Paget XXXXX plates are markedly fluorescent under the X rays. Coins in a box and the bones of a hand were distinctly visible when a plate was substituted for the fluorescent screen for visual examination. It is

suggested that this phenomenon of the fluorescence of a dry plate accounts for the photographic action of the X rays. Probably, as Mr. Walker suggests, any good, thickly coated plate, rich in silver, will fluoresce, so that his experiment is open to the verification of our readers. A dry plate would form an exceedingly cheap substitute for a fluorescent screen. An interesting letter on the subject, from Mr. Walker, appears in our Correspondence columns.

* * *

THE management of that popular place of entertainment, the Alhambra, have recently included in their programme a series of lantern-slide views of Buluwayo, and portraits of Matabele warriors, members of the defending force, and prominent Chartered Company officials. With remarkable unanimity the daily and weekly press characterise the Exhibition as poor and unsuited to the taste of variety-theatre audiences. Curious to ascertain for ourselves whether the press verdict was at all warranted by the quality of the slides, we recently took occasion to inspect them, and for once in a way were forced to agree with our lay *confrères*. We have seldom seen publicly exhibited such crude and depressing productions of the camera. In future, those who contemplate utilising photographs for entertainment purposes would do well to avail themselves of qualified advice in their selection. On the other hand, the projected photographs of animated scenes still appear to give great delight to the audiences.

* * *

A PHOTOGRAPHIC outing, of a somewhat unique character, is to be held from to-day (Friday) till Tuesday next. The Photographic Field Club, which was formed in 1860, has arranged for a visit to Ludlow, under the leadership of Mr. H. P. Robinson and Colonel Gale. We wish the party fine weather to enjoy the natural attractions of the beautiful Shropshire town. That an association, formed thirty-six years ago for the prosecution of photography as an outdoor pursuit should still be leading an active existence is a phenomenon which encourages us to hope that field photography will always be popular with thorough-going workers. Ludlow is a long way from London, and we are challenged to point to any *young* enthuslasts to compete with the Field Club veterans. We reply: Was there not a Convention excursion to Ludlow last year? and is there not a Convention meeting at Leeds this?

* * *

MR. JOHN CARBUTT, the well-known plate-maker of Wayne-junction, Philadelphia, sends us a copy of the Philadelphia *Public Ledger*, which contains an account of some interesting experiments with the X rays undertaken by Dr. Arthur W. Goodspeed, of the University of Pennsylvania. This enthusiastic student of science made himself the subject of the experiment. Taking a Carbutt X ray plate, sixteen by twenty inches in size, he placed it flat on a table, and then lay down upon it. The plate was just large enough to go between his shoulders. The tube was placed over the body at a distance of two feet from the plate. The current was turned on, and an exposure of forty-five minutes was made. Our contemporary gives a reproduction of the radiograph of the upper portion of Dr. Goodspeed's skeleton.

PHOTOGRAPHERS AND THE RAILWAY COMPANIES.

THE question of reduced railway fares to photographers is one that has often engaged the attention of photographic societies, though, unfortunately, with but one result. The first society to take the matter vigorously in hand was, if we remember rightly, the West London, soon after its formation; the last, the Hackney Society; but all to no effect. A petition to the companies to the same effect is now being circulated, and we heartily wish it every success, and we can assure our readers that, if it is, we shall be amongst the first to avail ourselves of any reductions that may be made.

There are generally two sides to every question, and there are to this—the photographers and the railway companies—and, as we mentioned a few weeks back, there were probably good reasons why the same privilege as anglers enjoyed over limited districts, at certain seasons, should not be accorded to photographers, over unlimited ones, at all times. The various railway companies have, at different times, duly considered the matter, and we are given to understand that the principal objection has been that the privilege would not be availed of for strictly photographic purposes only; and probably they have some ground for this. We have even heard of persons joining angling societies only for the advantage of cheaper railway fares, and probably the companies are not ignorant of the fact, therefore they are not altogether unreasonable in suspecting that a similar thing might happen if members of photographic societies were put on the same, and extended, footing as anglers, particularly as they know they are daily being defrauded by unscrupulous travellers. Of course, every one knows that no respectable member of a photographic society would use his privilege, if granted, improperly.

Let us look at the matter from a strictly railway company's point of view, not as counsel, but, as it is well to do so, in the case of any more petitions being presented, so that such objections as may be raised against them may possibly be met. It must be borne in mind that there are some three hundred photographic societies in the United Kingdom, averaging, say fifty members each—some have less, and others many more. The subscriptions vary from a few shillings a year upward, some being as low as half-a-crown. This means that 15,000 people ask for the privilege of travelling at reduced fares if accompanied by photographic apparatus. Now, a hand camera can be had so portable as to go into the pocket, or some for so low a price as a few shillings; hence any member of a "Little Pedlington" Society in existence, or to be formed, for the annual subscription of half-a-crown, and the outlay of a few shillings for a hand camera, would have the right to travel where he listeth at a reduced fare.

It was remarked to us some time ago by a railway director, when this subject was then to the fore, that, if the privilege was given to photographers, why not to footballers, cricketers, golfers, or other outdoor pleasure-seekers, as one of the reasons why the privilege should be granted is that the photographer only travels for pleasure and not for profit? This argument is somewhat on a par with that of the correspondent who wrote a year or two back that amateurs should be supplied with their materials on better terms than professionals because they made no profit by their use. It must be borne in mind that the major portion of railway travelling is not for strictly business purposes, and railway directors are fully aware of that.

Railway managers are business people, and business and sentiment do not go always hand in hand. It is the former that they consider first in the interest of the shareholders' dividends. What should be done to secure the desired reduction of fares to photographers is to convince the managers either that the present rate compels them to reach their

destinations by other conveyances, to their loss, or that, by reducing the fares, they would carry larger numbers of passengers, and in such an increased proportion as to compensate, or more, for the reduction in the fares; also, at the same time, show some guarantee that the privilege, if given, would not be abused by its being used for other than strictly photographic purposes. When this can be done to the satisfaction of the companies, we feel sure that what we all desire will be accorded without any largely signed petitions, humble or otherwise.

Another Amusing Query.—It will be remembered that a few weeks back we quoted from one of the evening papers an amusing query about photography, and the not less amusing reply it evoked. Here is another photographic query that has since appeared in the same paper:—

"(31,067) PINHOLE PHOTOGRAPHY.—I shall be obliged for recipes for sensitising, developing, and fixing.—*Au Naturel*."

Value of Pictures.—We have frequently referred to the high prices paintings by the old masters, at times make, and the abnormally low ones they are sometimes disposed of at auction in this country. At a sale in Paris, one day last week, a painting, *Diane au Bain*, by Watteau, was knocked down for 107,000 fr., equal to about £4280 English. The purchaser is said to be the Comtesse de Miranda—better known by her professional name, Mdme. Christine Nilsson. Clearly England is not the only country in which good pictures realise high prices.

Acetylene in Use.—It is stated that acetylene is being tried in some of the tram cars in Paris, and with promising success. The generator, containing the calcium carbide and water, weighs under thirty pounds, and is placed beneath the steps of the vehicle, and it contains sufficient material for generating thirty-five feet of gas. As the lighting power of acetylene gas is something like fifteen times that of coal gas, the cost is stated to be less than that of illuminating the cars by petroleum. Doubtless, after this, we shall have a practical and safe application of acetylene for lantern purposes next season.

A Proposed New Society.—*Apropos* of the article in a recent number, on *Photographic Societies and their Future Prospects*, a correspondent sends us a cutting from a suburban paper—an editorial paragraph. It is as follows:—

"We are glad to note that a movement is on foot for the establishment of a photographic society in Chiswick. There should be plenty of room for such an institution. To put it mildly, there are not too many societies in the district for the promotion of friendly intercourse, and an addition to their number is a healthy sign. The multiplication of institutions of this kind will do much to break down the spirit of cliquism which is characteristic of suburban districts."

But for the last sentence, we should have surmised that the writer was unaware of the existence of the West London Photographic Society, or that it held its meetings in Chiswick. We have, however, heard rumours of dissensions in the Society, and possibly the proposal of a new one may have something to do with them. The West London is a strong Society, and one that has done good work; as such, we hope it will continue. We can only reiterate what we have said before, namely, that one strong society is better than half a dozen small ones in a district.

Photography at the National Gallery.—The communication, in our last issue, from the Rev. F. C. Lambert, commenting on our article on Amateur Photographers and the Trustees of the National Gallery, is one that will not, we fear, be likely to cause the latter body to alter its decision. Indeed, some of the points raised appear rather to sustain it than otherwise. The Rev. gentleman suggests, with reference to the Trustees recognising the importance of the work being done well, "that an enthusiastic amateur who would not mind trying two or three times the same picture *might* get quite as good results as a professional who is neither able, nor willing to give so much time to the work." Now, supposing the amateur did, after several attempts, get a good result, of what advantage would it be to any one but himself? This is what the Trustees, no doubt, have in mind, and they, in their discretion also, we believe, limit the privilege of photographing the pictures to such professionals as they are assured understand their work, and are capable of producing the best results, and thus without having to make several attempts to obtain them.

IT must not be assumed, as some have done, that permission to photograph the national pictures is given broadcast to every professional that likes to apply. Mr. Lambert refers to the amateur "who is a duffer, who spends hours and pounds and produces only ghostly smudges." Still, he is an amateur photographer, and would have an equal right to practise on the national pictures as the most proficient, if amateurs had the right at all. The Trustees cannot be expected to examine applicants as to their proficiency, and where is the "duffer" that considers himself one? Mr. Lambert also alludes to the "capable and enthusiastic amateur who is willing to devote his abilities, time, and money to the furtherance of reproducing and popularising the great art treasures of the nation." It is a little difficult to conceive how the amateur could popularise the works, except by publication; then he would cease to be an amateur, and would be doing only what has already been done by the most skilful art reproducers and publishers in the world. If the Trustees relax the restrictions as to photographing the National pictures, it would, we suspect, be on stronger arguments than those yet brought forward in the interests of amateur photographers. Still, there is no reason why they should not be advanced.

Substitute for Diamond for Cutting Glass.—The time-honoured glazier's diamond seems in danger of being displaced by a cheaper substitute, even more efficient than the original instrument. It is reported that M. Moissan has discovered a means of forming a compound of boron and carbon by heating boracic acid and carbon in an electric furnace, the intense heat of which has already been the means of introducing into every-day use substances that hitherto were either unattainable or too costly. The new substance in appearance is black, something like zoophite; and its hardness is so great as to enable it to cut diamonds with ease. Unlike the results of previous experiments in artificial-diamond making, which were in minute particles, the new cutting material can be produced in pieces of any size required.

A Photographic Transit Circle.—Dr. H. C. Russel has recently devised a method which has solved a problem long wanting solution—a method of utilising photography for registering the transit of stars. It is claimed for it that it is equally good with faint stars as with those of higher magnitudes, and that it is capable of far greater exactitude than even the best of existing instruments. It consists mainly of a photographic and visual telescope—the former being thirteen inches in diameter—mounted together, and so arranged that it could be reversed in the polar axis and two images thrown on the plate. If they coincided, it would show that there are no errors of collimation due to flexure of the instrument, while, if a double image was produced, a point between the two star spots on the plate might be assumed to be the mean of errors.

Eclipse Photographs.—In view of the near approach of the next solar eclipse, much interest attaches to the *Report and Discussion of the Observations on Solar Physics*, recently presented to the Royal Society by Mr. Norman Lockyer. Messrs. Fowler and Shackleton's reports on the 1893 eclipse as observed in West Africa and Brazil were fully treated, and the general conclusions given under nineteen heads. It is noticeable that a certain effect, the pro-

duction of a line D_3, as shown in the 1883 eclipse photographs (*see* paragraph 9), is now supposed to have been caused by a photographic effect due to the unequal sensitiveness of the isochromatic plate employed. The last paragraph (19) is interesting as bearing on chemical theory, it strengthens the view that chemical substances are dissociated at a temperature so intense as that of the solar orb.

The Universality of Photography.—No better object-lesson on the immense value of photography in connexion with physical science could possibly be found than that afforded by the recent *conversazione* of the Royal Society. Objects of interest, on both natural and physical science, were shown, but the latter were predominant and attracted most attention; the novelty of Röntgen work not having worn off, the exhibits in connexion with it naturally attracted a great share of the visitors' attention.

Some of the Photographic Exhibits.—Of Röntgen rays and their action there were several demonstrations. Mr. Herbert Jackson showed how superior to all other substances was potassium platino-cyanide as a phosphorescent screen. It is a remarkable thing that, for many months before Röntgen hit upon the idea of utilising it photographically, Mr. Jackson should have been working with it, and have devised a form of Crookes' tube that at the present time holds the lead against all others.

Mr. Sydney Rowland exhibited electro-sciographs of a large variety of objects, mainly of surgical interest. About fifty examples were shown. They consisted of about twenty per cent. of sciographs of foreign objects, fifteen per cent. of diseased bones and joints, ten per cent. of bone deformations through tuberculosis, and a variety of other deformities of terminal bones and joints.

Mr. Friese Greene's apparatus for producing photographs at the rate of two or three thousand an hour for periodical illustration was shown, and attracted much attention.

Mr. J. Norman Lockyer, C.B., F.R.S., exhibited a glass prism of nine inches' aperture, constructed by the Brothers Henry, of the Paris Observatory, for the purpose of photographing stellar spectra. The construction of a prism would seem a simple enough matter, but the very highest degree of skill is needed to produce them so as to perform satisfactorily. A reflecting prism, for example, of a very few inches' diameter, could not be bought for a hundred pounds. The same exhibitor showed a variety of photographs, coronal spectral rings, spectra of stars, spectra of helium and gas in reference to the spectra of Orion stars, spectra of metals of the iron group, &c.

Mr. F. McClean, F.R.S., and Professor Hartley, F.R.S., also showed an interesting variety of photographed spectra, celestial and terrestrial.

Professor Worthington, F.R.S., and Mr. R. S. Cole exhibited photographs of splashes, of falling drops, and other bodies dropped into liquids. Photographers often speak of "instantaneous" work, but rarely is the title so justified as in the case of the splash pictures, for the exposure was about three one-millionths of a second.

Captain Abney, C.B., F.R.S., exhibited his apparatus, showing how to throw on a screen, or photograph on a plate, the image of a luminous object in monochromatic light.

Mr. Ives's stereoscopic photo-chromoscope was also a centre of attraction.

Shorn of all these objects of photographic interest, the *conversazione* would have been in comparison very commonplace and ordinary.

FOREIGN NEWS AND NOTES.

Interesting Experiments with the X Rays.—In the *Photographisches Wochenblatt*, 1. Gaedicke gives a very interesting account of some experiments he has made in the Röntgen ray photography, to determine the value of several substances recommended for screens. A screen was coated in sections with platino-cyanide of barium (Kahlbaum's), Balmain's paint, powdered fluor spar (ordinary), sulphate of quinine, platino-cyanide of potassium, natural fluor spar (very pure), and pentadecylparatolylketon. An induction coil, giving a spark of 11 cm., and a Hittorf's tube were used. An ordinary plate was dipped in a bath consisting of—

Water	1000 c. c.
Erythrosine dissolved in spirit 1:380	40 „
Solution of silver nitrate 132:1000	16 drops.
Strongest ammonia	4 c. c.

After drying, the plate was placed in contact with the screen, and wrapped in black paper and exposed. The results were compared photometrically and relatively to unprepared sections of the screen gave the following values:—

Barium platino-cyanide	9:1.
Potassium platino-cyanide	4:1.
Balmain's paint	2:1.
Both samples of fluor spar	1·6:1.

The other substances made no appreciable difference. It is noticeable that barium platinocyanide gives by far the best result, and Gaedicke reiterates the question, Do the Röntgen rays act directly on bromide of silver, or must they be first converted into light rays in order to act photographically? The order of efficiency of the screens corresponds with their order of fluorescence. There is also the important fact, remarked by Eder, that bromide of silver in a non-fluorescent medium, such as collodion, is insensitive to these rays. Gelatine is, however, a fluorescent substance, and Gaedicke thinks the bromide of silver may be affected by the fluorescent light emitted by the gelatine, which might be determined by experiment.

To Avoid Air Bubbles.—To avoid air bubbles in developing bromide or other papers, Liesegang, in the *Archiv*, recommends that they be immersed in the developer film upwards, and that the film be turned downwards before another sheet is placed in the dish. For the development of chloride papers, without inconvenience from air bubbles, he recommends the addition of alcohol to the developer, for instance:—

Water	200 grammes.
Gallic acid	1 „
Acetate of soda	10 „
Alcohol	50 „

Modern Printing Processes.—Jul. Raphaels writes concerning modern printing processes in the *Photographische Correspondenz*. If our prints are to appear "unphotographic," we must give as much attention to their production as to making the negative. Photogravure he pronounces unrivalled in this respect, but how few amateurs or professionals can work the process. After comparative experiments with platinum, bromide, and many sorts of printing-out papers, he gives the preference to matt-surface chloride, slightly printed and developed. Weak negatives give less satisfactory results than good negatives full of contrast. The developer to be used is important. Hydroquinone produces a reddish image, easily toned, and too like an ordinary print. Gallic acid is much better, producing olive-green to green-black tints, that do not require toning. The exposure should be a quarter to one-sixth of that given for a fully printed image. The developer:—

Water	100 c. c.
Concentrated alcoholic solution of gallic acid	5 c. c.
Fifty per cent. solution of acetate of soda	10 „
Alcohol	25 „

The print should be rather over-developed, then washed and fixed. To modify the tone, after development, the combined bath may be used.

Stripping Negatives.—Two methods for stripping negatives from glass are given in the *Photographisches Archiv*. The first by Mussat is on the following lines. The plate is first placed in a bath consisting of one part of the commercial formalin and ten parts of water. After soaking for five minutes, it is rinsed with water, and the film is cut through with a knife at about $\frac{1}{10}$ inch from the edge. The plate is then placed in a water bath and the temperature raised to about 120° Fahr. The film separates from the glass, and is transferred to a collodionised plate. It may then receive another coating of collodion, and can easily be separated from the temporary support. The second method, by Roy, recommends the use of a bath consisting of 100 parts water, 50 parts formalin, and 5 parts glycerine. The film is cut through at the edges and allowed to dry. To strip the film from the plate, place the negative for three minutes in a bath of 100 c. c. water, and 20 grammes carbonate of soda. Without washing, immerse it in a five per cent. solution of hydrochloric acid. The carbonic acid generated between the film and the glass will effect the separation. The film is then transferred to collodionised glass, recollodionised, and stripped. In either case the film does not expand.

The Apprenticeship System in Germany.—A recent case cited in the *Deutsche Photographen Zeitung* may encourage English apprentices to be more contented with their lot in this country. By recommendation of the Potsdam Military Orphanage a widow was induced to apprentice her son to a photographer. She summoned the man to show cause why the indentures should not be cancelled, as her son complained he could learn nothing at the establishment [?] It was admitted that the lad was set to work to make coffee, peel potatoes, clean boots, mend stockings, go to market, turn the mangle, and watch the baby, sometimes till one o'clock in the morning. He was also sent to other tradesmen to borrow money, and was once told to exchange the caps of his master's children, and, if caught, to say he was apprenticed with a certain tailor. The Court ordered the indentures to be cancelled on the ground that the lad had been taught to lie, but they also found that he had been employed too much as a servant. The master was ordered to give up the bed and other things belonging to the apprentice, but a counterclaim was set up for M. 100 (5*l*.) damages, for photographs spoiled. This was too much for the Court. The Judge exclaimed, "It is a disgrace to hear such a thing," and added he would call the attention of the managers of the Military Orphanage to the case and warn them against this master.

OVER-EXPOSURE AND CHLORIDE RESTRAINERS.*

THE four experiments which I am now about to describe will serve to give some idea of the capabilities of the iron bath, and of its power of controlling the growth of density.

The plates employed in the experiments were the Ilford (ordinary brand), and the exposures were made in a well-lighted room.

The first plate was exposed for thirty-five seconds on a portrait subject, the aperture of the lens stop being *f*-14, and the time of day 12.40 p.m.

Without any preliminary treatment it was developed in a solution made up according to the Ilford formula for normal exposures, each fluid ounce of developer containing

Pyrogallol	3 grains.
Crystallised sodium carbonate	22 ,,
Sodium sulphite	22 ,,
Potassium bromide	·5 grain.

When one minute and a quarter had elapsed, the image began to appear, and half a minute later it was visible in all its details. After the plate had remained in the bath for two minutes, the developer was diluted with water to half its original strength, and the development was continued for three minutes longer.

The standard negative thus obtained was clear, but vigorous, and showed no signs of over-exposure.

The second plate was exposed for fifteen minutes, the subject being the same as before, the aperture of the lens stop *f*-28, and the time of day 12.15 p.m. It will be observed that the exposure given in this case was about five and a half times in excess of what was required, the correct exposure being approximately two minutes and a quarter.

The exposed plate was soaked for twenty minutes in the standard ferric-chloride solution, and was gently rocked during the immersion. After being well rinsed in water, it was transferred to the developing dish. A freshly prepared soda developer (formula as above) was again employed. On being flooded with the developer, the film became instantly black all over. In the course of a few seconds the black colour changed to a deep brown, which grew gradually fainter and fainter, and in about two minutes' time entirely disappeared, leaving the film of its original hue. Two minutes more passed before the first outlines of the image became visible. The growth of density proceeded steadily, but remained quite under control. The process of development lasted eight minutes in all.

The finished negative was of good quality, *and showed no signs of over-exposure*. The range of contrast obtained was quite equal to that exhibited by the standard negative, though the tone was slightly colder than that of the latter, more resembling that produced by ferrous-oxalate development. Towards the foot of the negative a small portion of the image was eaten away at the point where the developer had first come in contact with the film. This would not have happened had the developer, instead of being poured over the surface of the plate, been transferred to the bath and the plate then dropped in.

The third plate was exposed for two minutes on the original subject, the aperture of the lens stop being *f*-14, and the time of day 12.30 p.m. The exposure given was about 2·4 times in excess of the correct one. The following developer was employed:—

Pyrogallol	2 grains.
Ammonium bromide	9 ,,
Ammonia (·880 s.g.)	10 minims.
Water	1 fluid ounce.

The exposed plate was immersed in the ferric-chloride bath and allowed to remain therein for ten minutes. After being thoroughly rinsed, it was suddenly dropped into the dish containing the developer. Instantly the film became of a rich coffee-brown colour. As before, the stain was rapidly bleached by the further action of the developer, so rapidly, indeed, that in the course of about a minute the film regained its original appearance. Fully six minutes more elaped before any trace of an image could be detected. Three minutes later the details thereof were clearly visible, but the growth of density was too slow to be perfectly satisfactory. Altogether the process of development lasted for a quarter of an hour.

The result was a fine negative, possessing clear shadows, fairly dense high lights, and remarkably delicate half-tones. There was, again, nothing in the appearance of the negative to indicate over-exposure, the image being in all respects such as might have been obtained by correct exposure and properly conducted development.

The fourth plate was exposed for two minutes and a quarter, the subject being again the same, the stop aperture *f*-28, and the time of day 1.15 p.m. In this case the exposure was practically normal.

The plate wee immersed for two minutes in the ferric-chloride solution which had been employed in the third experiment. After washing, it was transferred to the developer—pyro and ammonia, prepared according to the foregoing formula. The film darkened slightly under the action of the solution, but almost immediately regained its whiteness. Nearly three minutes elapsed before the image began to reveal itself, but, once it did appear, the development proceeded briskly, and at the end of another minute all the details were visible. In order that full density might be obtained, the process of development was, by an error of judgment, continued for seventeen minutes longer.

The resulting negative was thin and decidedly weak, the weakness being, of course, due to over-development. Nevertheless, the range of contrast which the image exhibited was far from inconsiderable, and could hardly have been obtained without the preliminary treatment in the chloride bath.

We see, then, from these experiments, that, by the simple means of a solution of ferric chloride applied to the latent image previously to development, the evils arising from excessive exposure may be completely checked.

We may also, from the same data, draw a few inferences as to the conditions and circumstances under which the remedy is likely to produce the best results.

Firstly, as to the duration of the exposure. The second experiment shows that we may safely give an exposure six or seven times as long as that which, in ordinary practice, we account normal. How much further than this the over-exposure can be carried I am at present, unfortunately, unable to state. Meanwhile, in the ab-

* Concluded from page 234.

sence of more exact information on this head, the working photographer had better not exceed the limits experimentally obtained.

As a safeguard against fog, it is desirable that the developer (particularly when alkaline) should contain a small percentage of a bromide. If the over-exposure be slight, the presence of a large percentage will unduly prolong the development; but, on the other hand, when we have to deal with exposures of not less than three or four times the normal duration, a strongly restrained developer may be employed with advantage. The third experiment may be cited in proof of this, though here, indeed, the bromide might well have been considerably reduced without detriment to the result.

As to the form of developer most suitable for use along with the ferric-chloride bath I can say but little. Of the two developers experimented with, I am, however, inclined to give the preference to pyro and ammonia.

Lastly, as to the conditions which must be regarded as essential to success. Perhaps the principal of these is, that the chloride solution be employed only when in a fresh and active state. Once its available chlorine is exhausted, the bath is of no further use for reducing purposes. On reaching this stage, it assumes a rich orange hue, due to suspended ferric oxide formed by the partial oxidation of the protochloride during the treatment of the latent image. Now, since we are obliged to increase the duration of the reducing process to suit the increase of the exposure, and *vice versâ*, it is evident that we must, for this purpose, employ a chloride solution of constant strength, otherwise we shall have to resort to guesswork to enable us to solve our difficulties. On this account the bath, after being once or at most twice used, should be discarded, and a fresh one substituted.

With a porcelain developing dish of the smallest size ($5\frac{1}{4} \times 4$ inches), two ounces of the solution will more than suffice for a quarter plate.

The length of immersion will, of course, wholly depend upon the exposure; but, to prevent failure, it may be recommended that each plate (whatever the exposure it may have received) be soaked in the solution for at least five minutes.

During the development, it will be found necessary to examine the image by transmitted light from time to time, in order to judge of the growth of density. It must not be forgotten that the real density is likely to be considerably less than the apparent density, owing to the translucent white coating of chloride of silver with which the film is overlaid. After one or two trials, the extent of this deceptive density can be easily estimated.

At some future date I trust to have an opportunity of contributing, by way of supplement to this article, a short paper on the reducing properties of the chlorides of copper and tin.

MATTHEW WILSON.

ON A NEW METHOD OF PREPARING PLATES SENSITIVE TO THE ULTRA-VIOLET RAYS.*

VI.—The Fixing.

The fixing is done in a solution of hyposulphite of soda (1 : 4), and proceeds much quicker than with ordinary dry plates. My small plates for photographing the spectrum in a vacuum readily fix in a few seconds. It is only when the film contains iodide that minutes are required. Silver iodo-bromide plates should always be kept horizontal and lie in the fixing solution face downwards, so that the silver-laden solution may fall quickly to the bottom and make room for fresher and more active solution. For this purpose evaporating dishes are most suitable, and, if chosen of suitable size, they have the further advantage that the plates as they lie can only touch the dish at the edges and corners and not on the surface, and can more easily be laid hold of and taken out of the bath without damage—an advantage not to be under-rated with small sizes. I prefer to employ two baths, the second for the after-fixing. In this way the negative does not require so much washing and keeps better. By long use the bath works more slowly, especially in fixing plates containing iodide. In this case a new bath should be made.

Plates without a binding material require very careful handling to prevent the image from floating away. In this case the film side must naturally be placed uppermost. When all the bromide is dissolved, the best plan is to remove the fixing solution with a syphon. The dish must not be shaken, at most it may be inclined a little at the last, as much as is necessary to run off the remaining fluid from the plate. The same care is necessary during the subsequent washing. When it is allowable, such films may be set fast with a gelatine bath after development. The fixing will be made very much easier thereby.

* Continued from page 248.

VII.—Washing after Development and after Fixing.

If the plate has been coated with gelatine and the silver bromide also contains gelatine, then it will stand a pretty strong stream of water without damage. In any case it can be washed without hesitation in abundantly flowing water. Greater care is necessary if there is no gelatine coating, or if the sensitive bromide contains no gelatine, especially if it is in a thick layer. In this case standing water is better. As a rule, the film stands better than one would expect.

After development I only wash a few seconds, and when it is a case of suddenly stopping the development I plunge the plate into the fixing bath without washing. I keep fixed plates in a stream of water for one to two minutes, and this is generally enough to remove the fixing salt. Larger sizes will take more time. I only work with small plates, and they dry on blotting-paper in two or three minutes. Most of the water runs down to the bottom of the plates, and is absorbed by the paper. The rest I shake off, or let it soak into a slip of blotting-paper I put on the edge of the plate.

Care must be taken not to touch the film with the finger while it is wet. It is very easily damaged in this way, although it will resist a stream of water.

If the plate is required to be dried off quickly, which is desirable for the better preservation of the sharpness of the image, then, after the water has drained off, I hold it close to a stove or lamp chimney. There is no fear of the film melting, as with a gelatine dry plate.

VIII.—The Negative Image.

The negative image forms a lustreless relief of a dark grey or brown colour. By rubbing with the finger, or better with some hard substance, it becomes like polished silver. Even dusting with a soft brush will often cause glittering silvery lines to appear. If the silver bromide contains no gelatine, the surface of the image is much more tender, and the employment of a brush to remove dust, &c., is quite impossible. (With plates containing gelatine the silver film worked over with a burnisher gives after a few strokes a bright silvery film, which is so resisting that it may be highly polished with a leather and rouge.) The image may be further protected by a coat of varnish or gelatine, but not without damage to the sharpness. That is the case, at all events, with line spectra; the conditions are not the same as with ordinary dry plates, in which the image is within the gelatine film; in the new plates it is more like a small silver rod on the gelatine coating. The silver particles which compose this little rod lie thickly and closely together in the best of my pictures; hence they show such extraordinary sharpness under the microscope. As soon as the varnish runs over these small rods it causes a swelling, which naturally must have some injurious influence on the definition of the edges of the lines upon which it falls.

XI.—The Intensifying.

Plates with a very fine grain sometimes fail in density. In this case they must be intensified. I hoped at first to be able to use silver intensification with advantage, but the trials did not answer my expectations. I have, however, obtained satisfactory results by bathing the plates in a solution of mercury bichloride 1·50, well washing, and then treating them with dilute ammonia at 1·10, followed by copious washing. As a rule the intensifying of spectrum negatives is not to be recommended, because it deprives them more or less of their original character and delicacy. The image should always derive the necessary density from the developer.

X.—Sensitiveness.

I have at present very few observations on this point. Until quite lately I had not the vacuum apparatus necessary for the proper treatment of this subject. Such of my results as are of importance for the purposes of this paper I give below.

Silver bromide is, as already stated, made more sensitive by the presence of silver iodide and gelatine. The same result occurs whether it settles in gelatine or if the grains of silver bromide are in contact with gelatine on one side only. Its sensitiveness is considerably increased thereby.

Plain glass plates were coated on one half with gelatine, and silver bromide was allowed to settle on them as before described, so that one half of the plate had a coating of gelatine with silver bromide above it, while the other was coated with the bromide alone. The two halves touched each other in a straight line which equally divided the image of the spectrum into two halves in the direction of its length. Each exposure gave a complete spectrum on both halves of the coating. When exposed to the spectrum of the sun, the gelatine half showed itself certainly four or five times more sensitive than the glass half. (If the gelatine coating shows any bubbles that have burst and left plain glass,

the precipitated silver bromide will be less sensitive in such places and show lighter points and circular spots. Bromide containing gelatine does not show this defect.)

These pictures were repeated with silver bromide that had been precipitated in presence of ammonia, as well as with some that had been precipitated from a solution containing gelatine. Attention was also paid to the thickness of the film of silver bromide. With the silver bromide that had been treated with ammonia the same difference between the two halves appeared as before, but, on the other hand, with that containing gelatine the gelatine substratum, as might have been expected, produced no effect. The explanation of this is easily understood: the sensitiveness of the silver bromide is so greatly increased by its being precipitated from gelatine and surrounded by it that the very much weaker action of the gelatine substratum has no visible effect. The same thing is observed with silver bromide free from gelatine, when it is exposed in films of greater thickness. Hence it is also easy to see that in this case the photo-chemical action of the rays of light only reaches the outer layer of the film which does not come under the influence of the bromine-absorbing action of the gelatine (H. W. Vogel), like the particles of bromide deposited directly upon the gelatine substratum. In this case the action on the two halves of the plate must be exactly the same.

The new plates are not very sensitive to sunlight. At a height of 120 metres above mean sea level (Leipsic), I obtained with a June sun wave-length 293·97 $\mu\mu$, and with highly sensitive dry plates under the same conditions, with only a third of the exposure, wave-length 293·70 $\mu\mu$.*

With an exposure of such duration (40 minutes) as was necessary for this, the spectrum on the ultra-violet sensitive plate breaks off sharply as an opaque band of action at wave-length 297·38 $\mu\mu$, and runs on further from there in distinct lines on a clear ground as far as wave-length 293·97 $\mu\mu$. This clear glass ground in the neighbourhood of the most refrangible ultra-violet rays of the sun is an advantage of the new plates. Under the same circumstances, ordinary plates give thick fog, in which the most refrangible lines become first of all indistinct, and, if an effort is made to photograph them more clearly by longer exposure, they disappear entirely. On account of this defect the observation of the most refrangible rays of sunlight on ordinary plates is made considerably more difficult. At the same time, they are always to be preferred on account of their greater sensitiveness.

The new plates can only come into question in cases where they excel both in intensity and in sensitiveness. This first occurs at wave-length 220 $\mu\mu$, and from this point onwards their sensitiveness increases. Consequently their greater working power is more in their unusual intensity, and is based on the fact that, in consequence of their small sensitiveness for the less refrangible rays, there is nothing to hinder their being exposed for a long time without becoming thickly fogged as ordinary dry plates do. The origin of this fog is diffused light arising from the inside of the prisms and lenses of the spectroscopic apparatus, of which the principal part consists of rays for which gelatino-silver bromide emulsion is much more sensitive than pure silver bromide.

Since the use of gelatine has so distinctly improved my pictures of the less refrangible rays of the new spectral region, there was no reason for excluding it, for the opening up of the remaining part of the spectrum as far as wave-length 100 $\mu\mu$. My attention was first of all attracted by its presence about the limits of action of the plates employed. Circumstances have unfortunately not yet allowed me to approach more closely a solution of this question.

The resumption of my experiments on plates should quickly settle the behaviour of pure silver bromide with regard to wave-length 100 $\mu\mu$, and, as the following considerations will show, there is some hope of success.

If one considers, that is to say, that gelatine even in a thickness of only 0·00004 mm., sensibly weakens the rays of wave-length 185·2 $\mu\mu$, and that in still much thinner layers it apparently stops all photographic action of ordinary dry plates near wave-length 182·0 $\mu\mu$, and, on the other hand, that the course of its absorption curve between 220 $\mu\mu$ and 182 $\mu\mu$ shows no increase, but rather a lessening of its transparency for the rays of the more strongly refrangible region, it is quite a surprise that, in opposition to this, it should be practicable to photograph the extensive region of the smallest wave-lengths, as I have ventured to designate the part of the spectrum lying between 185·2 $\mu\mu$ and 100 $\mu\mu$, by means of gelatine. An explanation of this is to be found only in the sensitising action of the gelatine, which possibly gets the upper hand in the struggle with absorption, and begins to lose it where the range of action of the new plates ends.

Under these circumstances it may be expected that the discovery of the unknown spectral region beyond wave-length 100 $\mu\mu$ is reserved for the pure silver haloid. Gelatine will, however, in this case also hardly be superfluous, because, when used as a substratum, it forms the only possible means of increasing the sensitiveness.

XI.—The Keeping Qualities of the Plates.

I have kept plates prepared in different ways for a long time in order to test their keeping qualities from time to time. They were kept unpacked in a light-proof cupboard, and consequently were not protected against the action of the atmosphere. From my experience with gelatine emulsions I was afraid they would show unevenness in their coating, and above all increased fog round their edges and a greater development of the imperfections of their surfaces. Pictures taken with them show, however, the contrary. The plates work even more cleanly after keeping than when freshly prepared, and some kinds were even more sensitive. I did not, however, make comparative trials with the sensitometer. My experience is founded only on the photographic pictures of the new rays beyond 185 $\mu\mu$. According to this, the new plates can be kept quite as long as ordinary dry plates. Compared with those coated with an emulsion containing silver oxide and ammonia, they show even far superior keeping powers.

On the Employment of the Plates Sensitive to the Ultra-violet.

The plates were intended from the very commencement for photographing the spectrum, and have hitherto only been used for that purpose. How they answered (and, not less, in what points they still failed) is shown in the foregoing account, and further in my former paper I have pointed out their good and bad qualities impartially, because I did not wish to promise more than they could be trusted to perform. I therefore consider disappointments in their use as entirely excluded from discussion.

As a measure of their actual capabilities the spectra 11 and 12 on Plate V. of the above-mentioned paper* may be referred to. It may, however, be remarked that the definition of these spectra has suffered from defects in the crystal of the fluor-spar prism employed, and that the same plate exposed to the diffraction spectrum has given a clearer picture. A proof of this is afforded by my enlargements to more than 300 times of the diffraction pictures of the rays 162 $\mu\mu$.

The sharpness of my negatives has here and there led to the belief that the new plates can be used advantageously for astro-photography. Against this, however, there are two important obstacles, the want of sensitiveness and the formation of a round grain in the negative.

For the rays of light with which astro-photography has to do, the plates hitherto in use are many times more sensitive than the new ones. The use of the latter could only be thought of with considerably prolonged exposures. Astro-photography, however, requires the exact opposite, shortening of the exposure. Further, the disc-shaped negative grain arising from chemical fog, as has already been fully explained, is so like the picture of a star that some of my plates have quite the appearance of a picture of the starry heavens. Under such circumstances mistakes could hardly be avoided in star pictures. In that case, too, the precautionary measures that have hitherto been employed for recognising defects of the plates will not have the desired effect, because the grain alluded to often comes out very strongly. Both defects outweigh the advantage of greater sharpness of image to such a great extent that the new plates cannot be recommended for astro-photography, and for professional photography still less. The only use they might find would be for line reproductions. The perfect sharpness with which they reproduce lines and their absolute opacity would certainly place them in the first rank for this, if the preparation of faultless films over large surfaces did not only involve considerable difficulties, but was also too costly and took up too much time to play.

I have not used them for portrait or landscape photography, but for the same reasons, and still more on account of the want of half-tones, they are quite unsuitable for such purposes.

They completely fulfil only their original object, the observation of the rays beyond wave-length 220 $\mu\mu$, but for this purpose they are at present not to be replaced. Victor Schumann.

(To be continued.)

* Both lines belong to the extension of the ultra-violet sun spectrum discovered previously by Herr Oskar Simony. I took their wave-lengths from the drawing published by A. Cornu in the *Comptes Rendus* (vol. cxi.), of this part of the spectrum extending to wave-length 292·22 $\mu\mu$, which was made from Simony's original photographs.

WELLINGTON'S IMPROVEMENTS IN MEANS FOR FACILITATING THE SEPARATION OF GELATINE COATINGS FROM PAPER SUPPORTS.

Mr. Wellington's invention relates to a mode of preparing a paper support upon which a photographic film, consisting wholly or in part of gelatine, can be coated, from which support the photographic film can be stripped prior to its being coated with emulsion, and he thus describes it:

"My invention consists in the treatment of a temporary backing of paper with a substratum which permits the ready stripping of a gelatine coating made upon it from this support. The said treatment is based upon the employment of gums in alcoholic solution as this preparatory substratum.

"In carrying my invention into effect, I coat upon any suitable paper, as for instance, upon the well-known photographic paper coated with baryta, whether matt or calendered, a substratum containing a suitable proportion of any gum or resin dissolved in any of the well-known solvents which are in general use for this purpose. In practice, I have found that good results may be obtained with gum mastic and gum, thus: in varying proportions dissolved in methylated spirit, or with other gums and resins, as, for instance, damar, copal, and their congeners, but I preferably use gum sandarac or gum copal. The consistency of the solution of these gums is in like manner capable of considerable variation, and will depend, in great measure, upon the means which are adopted for coating the paper; for instance, if the paper be coated by immersion in a trough, a solution of one part of gum sandarac or gum copal, and ten parts of methylated alcohol will be found to answer satisfactorily.

"Having thus prepared my paperbacking by coating it with a substratum of gum, and permitted it to dry, I proceed to coat thereupon a layer of gelatine, which may, if desired, be rendered insoluble by the addition thereto, immediately prior to coating, of a suitable proportion of soda alum, chrome alum, or any of these well-known chemicals which have the property of rendering gelatine insoluble when dry.

"Upon this gelatine I may coat a celluloid film, preferably doing this in the manner set forth in the specification of Letters Patent, No. 14,274 of 1893.

"The film body may, in like manner, be formed of any transparent, non-hygroscopic material other than celluloid, which is capable of conjunction with, that is to say, adhering to the gelatine substratum in the manner set forth.

"If desired, in lieu of coating the gummed paper with gelatine and the latter with celluloid, and then, after stripping the film from the gummed paper, applying sensitive emulsion to the gelatine surface of said film, I may apply a sensitive emulsion direct to the gummed paper, and afterwards apply a backing of celluloid or other suitable transparent material thereto.

"When the film body, however composed, has become thoroughly dry, I strip it, together with the gelatine upon which it was coated or of which alone it consists, from the paper backing, preferably by winding the film upon one roller and the gummed paper backing upon another roller, the function of the substratum of gum proposed in my invention being to facilitate the separation of the gelatine from the paper. In case the gelatine film has been coated with celluloid or other transparent, non-hygroscopic material, the film obtained may then be coated with sensitive emulsion, the gelatine surface being particularly well adapted to receive, and to cause, the adhesion of the sensitised vehicle.

"The claims are: The improved means for facilitating the separation of gelatine coatings from paper supports in the manufacture of photographic films. In means for facilitating the separation of gelatine coatings from paper supports in the manufacture of photographic films, the interposition of a coating or substratum of gum between the paper and the gelatine coating."

COLOUR IN NEGATIVES.*

Experiment A.—We will first take the case of a normally exposed plate—say one that will develop to full printing density in about three minutes without any further additions to the developer. Such a negative, after rinsing under the tap, is fixed, as usual, in hypo, and then washed again, and, when dry, will be found to have a small amount of yellow colouration in it, not very much, but still it is there, as comparison with a metol-developed plate will prove. It is just enough to give us the desired richness in printing.

Plate No. 2 shall prove to be a bit under-exposed. When it makes its first appearance, we quickly decide that it wants a fillip, and we add accelerator composed of soda carbonate and soda sulphite. Probably, before it is finished, we give it another dose, and, if it is an extreme case, we may even soak it in accelerator only. This plate, when dry, will be quite different in colour to No. 1. The more accelerator there has been added the greyer the colour, until, in the extreme case, it will be nearly as pure and as free from stain as a metol plate.

* Concluded from page 236.

Plate No. 3 shall be known beforehand to be grossly under-exposed. This one we shall not put into a normal developer, but we will reduce the quantity of pyro until we have only a quarter of a grain of pyro and one-sixteenth of a grain of bromide present to the ounce of mixed developer. The deficiency in quantity is made up by adding water, whilst the amount of accelerator remains constant. This plate will be a very long time developing, and we might expect a deep yellow stain to result, but the sulphite of soda is so largely in excess of the pyro that it, to a large extent, prevents this, and, when finished, it will be found to be only a little deeper in colour than plate No. 1.

Plate No. 4 shall prove on development to be over-exposed. We immediately dose it with pyro and bromide stock solution; if very bad, by adding a few drops of ten per cent. bromide solution. This plate will also take a long while to attain density, and will have most colour of all—a great deal too much, in fact, making it a very slow printer.

Now we have four negatives that differ enormously in colour when dry. We can modify to some extent those that have too much colour by soaking in a bath of alum and acid (citric or hydrochloric), but we cannot impart colour to the grey one. The nearest approach is a dilute bath of bichromate of potassium, but it doesn't give us exactly the same result as would the pyro colour proper.

All this you, doubtless, know. Well, we will try again.

Experiment B.—Four plates of equal exposures (and that normal) shall be developed in the normal developer for an equal length of time—say, three minutes. On removal from the developing dish, allow one to wash under the tap for thirty seconds (time it with your watch), and then transfer to the hypo. No. 2 wash for thirty seconds, and then allow it to drain in a rack for thirty seconds before fixing. No. 3. wash one minute and fix. No. 4 wash one minute and drain one minute, then fix. These four plates when dry will again give us different results. No. 1 will be about right, Nos. 2 and 3 will be decidedly yellower, and No. 4 nearly as bad as No. 4 in Experiment A.

Did you know that before, or have you ever utilised the knowledge?

Experiment C.—Four more plates. That makes a dozen! Ah, well! 'tis only 1*s.*, and we may learn something from it. All four shall be normally exposed, developed for three minutes, washed for thirty seconds, drained for thirty seconds, and then fixed. Whilst they are in hypo prepare an alum bath, strength about three per cent. No. 1 plate shall wash after fixing for one minute, and then be transferred to the alum bath. No. 2, three minutes' washing followed by alum. No. 3, five minutes' washing and then alum. No. 4, transfer to the washing tank without any washing at all. After drying, comparison will again teach us much. No. 1 will resemble No. 1 in Experiment A. The others will progress in colour until No. 4 will have a sort of olive-green tint, which will be very objectionable in this particular negative, but which would be invaluable in a thin negative that would otherwise print much too weak and flat.

If you care to break into another dozen plates for experimental purposes, you will find that shorter or longer soaking in alum will give more or less colour, but the differences are not great. After drying, you might also try the effect of alum and acid on the various plates. Plate No. 1 in each experiment will be deprived of almost all its colour. The others will give up less and less of their colour to the acid solution until, with No. 4 (Experiment C), you will find that the colour (if discharged at all) re-forms during the final washing, and when dry it will be as yellow as ever.

Now see how you can ring the changes in producing or repressing colour in a negative. To put it to a practical test, we will go back to Experiment A. This is how I should have dealt with those four plates. No. 1, normal exposure and normal development. (I must premise that I much prefer all plates, if possible, to be alumed; they dry quicker and more evenly.) Therefore I should wash it before fixing about thirty seconds, let it drain fifteen or twenty seconds, fix ten minutes, wash one minute, alum one minute, and transfer to washing tank. No. 2, under-exposed, added accelerator during development. I should wash at least three minutes, and set aside to drain for another minute before fixing. After ten minutes in hypo, wash until a good body of colour forms in it (probably about three minutes), and then alum. Supposing it have an extreme case which had needed soaking in accelerator, I should plunge it for a moment or two into old normal developer to overcome the excess of sulphite in the film. This should be done when development is considered complete, and it must only be for a very short time, or the high lights will begin to gain undue density. Then proceed as before. If after fixing, it still did not gain enough in colour, I should omit the alum bath, and I *have* gone to such lengths as to return it to old, discoloured developer after fixing if I could not attain the colour any other way. No. 3 will probably do with thirty seconds' washing, and no draining before

hypo. After fixing treat as No. 1. No. 4, over-exposed, very prolonged development, additional pyro, &c. I must keep the colour down as much as possible. Five seconds' washing with the tap full on, slip it into hypo quickly, and let it stay there at least a quarter of an hour. I won't look at it until it has been thoroughly fixed and through alum, because I know that every moment it is exposed to the atmosphere will help to form colour in it. At the end of the time decided on for fixing slip it out quickly, just a perfunctory rinse under the tap—not more than five seconds—and then into alum for half an hour. I know it will spoil my alum bath by carrying hypo over into it, but I value my negative more than I do the alum. After this, it will require more than the usual amount of washing, as the film will be very tough. After drying—not before—alum and acid may be resorted to if necessary.

I think I have said enough to show how the thing works. You will find, in practice, that it is much easier than it reads. I do not advise a greater proportion of sulphite in the developer than that given, because if more is present it means proportionately longer washing, &c., to attain the desired amount of colour. As before stated, I much prefer a negative to go through alum, therefore I always wash long enough before fixing to make the alum bath a necessity afterwards.

My negatives, at one time, were of all sorts and conditions of colour, and I was much puzzled to know why. Having found out the reason, I was not long in putting the knowledge to further use, as above described. Briefly put, the matter resolves itself into this: Pyro-soda or pyro-potash developed negatives, if washed and drained sufficiently before fixing, acquire the power of turning yellow after fixation, and this in such a gradual manner that it can be stopped at any desired moment by the use of the alum bath.

The two extremes may be stated as follows: A negative, harsh in contrast, which I should endeavour to keep free of colour, that it might print softer, and a negative lacking in contrast, which I should make yellow to increase the brilliancy of the resulting print. Or, again, they may be an under-exposed, forced negative, lacking the necessary vim and go for printing, and a thick, dense, over-exposed negative, which in itself, without colour, would prove a slow printer. The remedies for the latter two are apparent from what has gone before.

In conclusion, *if* you wish to have an even, grey colour to all your negatives, and do not want the additional power which is thus placed in your hands, it is only necessary to use an acid fixing bath, or even a small proportion of ordinary sulphite in the hypo bath, and you will not be troubled with colour in your negatives. It is, however, not a trouble to me—it is an advantage—*when under control.* W. E. A. Drinkwater.

BRUSHING.

Of the many manipulations connected with the practice of photography, perhaps there are none deserving of more consideration, and which, at the same time, receive so little attention at the hands of photographers generally, than the use of a brush in development, and other equally important operations connected with an all-round practice.

No doubt, the use of a brush is strongly urged by some plate-manufacturers, in combination with the ordinary application of a quantity of developing solution to a sensitive plate by means of flooding the developer over its surface, and the Platinotype Company have been instrumental in drawing the public's attention to the advantages of this method of developing their admirable printing papers, chiefly through the medium of an excellent little handbook, and which they circulate among all the dealers for the purpose of giving instructions as to the best means to follow in the working of their sensitised papers. But, with the vast majority of workers, the idea of using a brush in many of the ordinary operations connected with the practice of photography is almost entirely unknown, or at least the writer has found it so during the course of a pretty wide experience among a large number of members of the various photographic societies in the west of Scotland.

Of the numerous uses or applications to which a broad camel's-hair brush may be put with advantage, perhaps there is none more strikingly practical than the part such plays in the development of prints on large or small-sized sheets of bromide paper. Any one who has never seen a brush used, and who happens to be a witness for the first time to the bringing into view by means of development of such images by the merely passing across the surface of the paper a soft camel's-hair brush well charged with developing solution, invariably gives vent to an expression of surprise at the extreme ease and simplicity of such an operation, as compared with the more commonly practised and cumbersome method of flooding the entire surface, very probably, of a large-sized sheet of paper with a considerable quantity of expensive developing solution.

It only wants to be once optically demonstrated to cause the brush being for ever afterwards adopted for such a purpose.

But very little consideration will be required by any one having experience in the development of enlargements on bromide paper to see at once that not the least of the advantages pertaining to the use of a brush lies in its *economy*. With metol at 2*s.* 6*d.* per ounce, and which is now so much in vogue for the development of bromides, and which bids fair to rival and supplant our good old friend, ferrous oxalate, this question of economy alone becomes an important factor, for, in reality, the adoption of brushing in place of flooding necessitates the employment of a very much smaller amount of developing solution (probably only one-fifth of what is required in flooding) when such is employed to the entire surface of a print in one full wave of developer.

It is not, however, on the score of economy alone that the advantages lie with the use of a brush; there are several others of which mention should be made, viz., the power an operator possesses of retarding or hastening the development of any desired portion of the image during the time such is seen coming into existence. With a brush the entire operation of development is at all times completely under control, and many a fully exposed proof can be manipulated in such a manner as to cause the same eventually turning out an acceptable print, which, by the method of flooding, would only yield poor, flat results; whereas, when brushing is resorted to, at no time does an operator lose control or allow the image to get beyond his being able to retard or accelerate the development of such as a whole or in part, for by means of one or two extra brushes, which should always be kept at hand, well charged by soaking the same in specially prepared redeveloping solutions provided for this purpose, certain portions may be kept back, and others hastened forward in quite a marvellous manner to those unacquainted with this extremely useful and practical method of development.

Any one who for a moment gives this subject a little thought, and who judges these manipulations from a common standpoint, is very apt to imagine that such a method as I am advocating is more liable to cause streaks or surface markings than would be the case with the old, or rather more commonly practised (for brushing is not a new idea), method of flooding the entire surface with one full wave of the developer; but in practice such objections do not exist, although those workers who have never seen a print brushed into existence are very liable to imagine that such would be the case; and especially is this so with those who, for the first time, are eye-witnesses of the operation, for the first brush marks invariably bring into view those parts where the brush has applied the developer at the very outset, somewhat in advance of those parts where the brush was applied a few seconds later on. A very short time is needed, however, to show how beautifully all this seeming irregularity is dispelled, for, in a very few seconds, the parts where the brush was latest applied catch up the earlier strokes, and all the portions develop out in beautiful regularity without any of the attendant difficulty and mess nearly always present when dealing with the slunging of large quantities of developing solution in large wooden or other kinds of dishes.

By the use of these extra brushes high lights can be retained and strength added to shadows and the other black portions of a positive image in quite a marvellous manner.

It is not only, however, in development that brushing proves particularly useful in the hands of an operator. As I write these lines, I see before me the results attained by means of a brushing operation that would have been quite impossible of accomplishment without the services of such. I refer to the advantages a brush confers in the application of a solution of mercury to certain portions only of a negative that required being strengthened in parts without applying such as a whole.

In such cases as this, no doubt, brushing confers a great advantage, and much may be done to even intricate parts of a negative by means of a brush that cannot be treated in any other way.

The partial intensification of negatives has always been a subject of much importance with advanced workers, and a good many somewhat intricate dodges have been resorted to from time to time whereby certain parts of a negative are specially prepared with some preservative temporarily, so as to permit of other portions receiving an application of mercury without the same affecting the parts so shielded. Indiarubber solution, gum, and, in some instances, varnish, has been used for this purpose of temporarily protecting the parts that were already dense enough. In my experience, all such expedients are unnecessary, for the parts it is intended or desired to intensify can be easily treated with mercury by means of a broad or

finely pointed camel's-hair brush in an extremely effectual manner by simply touching such parts with a damp brush, or, in other words, with a brush that is not overcharged with mercury.

To those anxious to try this method of working I offer the following suggestions. Any negative that it is desired to intensify in parts only should be first well soaked in cold water until the entire surface of the film becomes soft; it is then placed away on end to drain in some cool place; in about an hour's time all the water that the gelatine has not absorbed will have left the surface of the negative, the film of which will now be in a soft and somewhat swollen condition, but there will be no surface water that could possibly convey by running any mercury that is applied to its surface by means of a brush.

When the negative is in this damp condition, it is either placed on a retouching desk, or, preferably, on a horizontal support with a white reflector underneath. A suitable brush, according to the size of the parts it is intended to apply the mercury at, is then used in a *damp* state, charged with the intensifying solution, and with this those parts only are treated; in a few minutes it will be seen that such begin to thicken up nicely. Broad parts can be treated with a flat brush. Then the negative is well washed again, and finally the ammonia solution applied. Such is another of the many advantages of using a brush, and, once an operator begins to taste of its great utility, he will never discard it. T. N. ARMSTRONG.

PHOTO-CHEMICAL NOTES.

Solubility of Silver Haloids in various Solvents.—Some time ago, Professor E. Valenta published the results of experiments made to determine the solubility of the silver halogen salts in their various solvents (see THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1896, p. 957). Herr Ernst Cohen, in a recent paper (*Zeit. Physikal. Chem.*, 1895, pp. 1861–9), points out that the figures given by Valenta are not those deducible from the equations according to which the solvent action is supposed to take place, at any rate as far as potassium cyanide and sodium thiosulphate are concerned. He has therefore examined these solubility phenomena, and finds that silver chloride, if not present in excess, dissolves in sodium thiosulphate solution according to the equation—

$$3Na_2S_2O_3 + 2AgCl = (AgNaS_2O_3)Na_2S_2O_3 + NaCl.$$

If, however, the argentic chloride is in excess, a less soluble salt—$Ag_2Na_2S_2O_3$—is formed. Potassium cyanide also exerts its solvent action on chloride of silver, if not in excess, according to the equation—

$$2KCN + AgCl = KAg(CN)_2 + KCl.$$

whereas, in the presence of excess of silver chloride, the above double salt is partly decomposed with the formation of silver cyanide and potassium chloride. These two latter compounds can act in the reverse way until a state of equilibrium is reached. It is stated that Valenta's results were due to the fact that he operated with a large excess of silver haloid.

Estimation of Formaldehyde.—The employment of formaldehyde or "formalin" in photography renders some means of ascertaining its strength desirable. M. Klar (*Pharm. Zeit.* pp. 40–611) proposes the addition of an aqueous solution of aniline by which methylene aniline is precipitated and may be filtered off, dried at 40° and weighed. A more expeditious method, however, is to titrate the excess of aniline in the filtrate using Congo red as an indicator. A standard decinormal solution of hydrochloric or sulphuric acid is gradually added from a burette until the red colour acquires a strong bluish tone, remaining unaltered on the addition of a further small quantity of acid. The original aniline solution is similarly titrated. Each cubic centimetre of decinormal acid represents ·003 gramme of formaldehyde.

New Reagent for Bromine and Iodine.—Solutions of metallic iodides or bromides when mixed with dichloro-benzine sulphonamide have their respective halogens liberated. This reagent is recommended by J. H. Kastle (*Amer. Chem. Journ.*) as a substitute for chlorine water. It can be used either in the solid state or in solution in carbon bisulphide. By its means ·0000127 gramme and ·0000065 gramme iodine together with ·04 gramme and ·0036 gramme bromine respectively may be recognised.

New Method of Preparing Oxygen.—Now that hydrogen peroxide is becoming a fairly cheap article of commerce, it may be practicable to employ the extremely convenient and easy method of preparing oxygen gas from it which a writer named Dioscoride Vitali has recently introduced (see L'Orosi, 1895, 1–5). When hydrogen peroxide is added to ammoniacal solution of copper sulphate, oxygen is evolved in abundance in the cold. An indefinite quantity of the dioxide can be decomposed by means of the same quantity of the copper compound. Hence, by allowing hydrogen dioxide (3–4 per cent. sol.) to drop from a tap funnel into a saturated solution of ammoniacal copper sulphate (20–30 c. c.) contained in a capacious Woulfe's bottle, a supply of gas can be most easily obtained. The gas is dried and purified from ammonia by passing through sulphuric acid. The *rationale* of the reaction appears to be similar to the decomposition of potassium chlorate in presence of manganese dioxide, the cupric compound reacts with the dioxide, yielding a cuprous salt and free oxygen, and the cuprous compound is then re-oxidised by another portion of the peroxide.

The Presence of Ozone in Oxygen.—Any one who has prepared oxygen from potassium chlorate and manganese dioxide is aware of the intense odour of the gas thus obtained. It was formerly thought that this odour was due to chlorine or an oxide of chlorine in the gas. Experiments, however, made within recent years have shown that the odour is due to ozone, and that only a trace of chlorine is evolved. A paper by Herr Otto Brunck on this subject (*Zeit. Anorg. Chem.*, 1895, 10, pp. 222–247) throws light on this question by showing that oxygen gas when passed over heated manganese dioxide is partially converted into ozone, and that increasing the quantity of manganese dioxide used in preparing oxygen raises the proportion of ozone in the gas. Herr Brunck has exhaustively examined the action of most of the metallic oxides in this respect, and finds that they all act in the same way, though none of them so powerfully as manganese dioxide. G. E. BROWN A.I.C.

The Inquirer.

*** *In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* JOURNAL *useful and instructive.*

CHLOROPHYLL.—ORTHOCHROMATIC writes as follows: "The recent mention in The Inquirer column of chlorophyll as applied to collodion emulsion induced me to try its effect as an orthochromatising agent, as I have some recollection of seeing a statement by Mr. Ives, I think, to the effect it may be used in collodion emulsion without any free silver. If this be so, it is in the highest degree important, since, in the first place, an orthochromatic emulsion can be made that will keep, and, secondly, sensitiveness to the less refrangible rays being the weak point of collodion emulsion, practically greater sensitiveness will be gained. But I have tried it and failed, failed in so far that I find chlorophyll absolutely inert, neither beneficial nor the reverse. I have added it to washed emulsion and used it both wet and dry, and also under the same conditions with emulsion unwashed; I have exposed without a coloured screen and with, but without finding the slightest difference in action. The chlorophyll has been extracted from the leaves of the common periwinkle as well as from those of ivy, and the only difference I can find between them is, that in a given time the latter yields a far stronger solution. Mr. Ives has had considerable experience in this direction, perhaps he can tell me what is wrong or why I have failed."

SULPHITE OF SODA.—AN OLD AMATEUR writes: "*In re* the 'Amusing Reply' discussion I am reminded that the sulphite of soda of to-day does not appear to be the same or to behave in the same manner as that obtainable ten or fifteen years ago; or, as a matter of fact, much of the product now supplied by photographic dealers is anything but pure sulphite of soda, as may be proved by directly comparing it with the pure article obtained from a reliable source. Whether the difference is wholly due to partial oxidation, or whether there are other impurities present beside sulphate, I am unable to say, but I think it would be useful, not only to myself, but to many others, if some fairly easy test for sulphite of soda were available. When I first commenced to use sulphite in the comparatively early days of gelatine, four grains to one of pyro would keep the plate perfectly free from stain; but with many of the plates of the present day a saturated solution will barely do so. The plates themselves may differ, but I can scarcely comprehend the possibility of the whole of the difference lying there; the pyro as Mr. Cadett suggests, may vary, but *I* think myself it is far more likely to be the sulphite. In former days I failed to notice any retarding action on the part of sulphite; now, with the substance so called, 'Made in Germany,' I suppose development takes three times as long. As amidol, metol, and suchlike owe most of their developing action to the sulphite, it seems to me that the matter is one of importance. Is such a test as I suggest available?"

DEFECTIVE COLLODIO-CHLORIDE. (To J. P.).—In reply to this query, I think, perhaps, one of the principal inducing causes may have been the use of solvents containing too large a proportion of water, or the addition of too much water in sensitising the emulsion. Of course, the employment of an unsuitable pyroxyline, as suggested, will have more or less effect on the result; but, with good solvents, there is a very wide latitude in this respect, whereas, when the latter are weak, the best pyroxyline will fail to work satisfactorily. J. P.'s symptoms all point in the direction of too much water. A collodion or emulsion free from water gives a close and structureless film; but, under reverse conditions, it is "crapy," and uneven, and runs, as described, in ridges and lumps. The tendency to solidification, which is always present where there is a considerable excess of acid in the emulsion, is also greatly increased by weak solvents, so that, on the whole, I fancy, if J. P. will look back, he will trace his difficulty to the source I mention. The remedy is obvious. The best way to treat the solidified emulsion is to extract the silver, and send it to the refiner.—SYNTAX.

TONING DIFFICULTY.—W. HALLIDAY writes: "My experience is similar to that of 'Redgauntlet' in the matter of the loss of toning power in preserved albumen paper. I am strongly of opinion that, although it is easy to prepare a sensitised paper that will keep perfectly colourless for several months—properly stored, of course—and will then print to a rich, good colour, there has yet to be discovered a method by which the original toning powers are preserved. Some years back, before the advent of gelatino-chloride, I was greatly troubled in this direction, as my practice was, as an amateur, to make a few prints as opportunity occurred, and to allow them to accumulate until I had a sufficient number to tone and finish. Sometimes a portion of the batch toned might be weeks old, while others were perhaps on new paper, and the results were anything but satisfying, either in uniformity or quality. I set to work experimenting with a view of 'preserving' my own paper, but I was forced to the conclusion above recorded, after trying a great number of methods and preservatives. Paper only a week old, when compared with freshly sensitised (and preserved), a new bath and precisely similar conditions being observed in both cases, showed a distinct difference in behaviour, and this steadily increased with time. A slight, or even a very marked, discolouration in keeping is of little consequence, as this will generally disappear in toning and fixing, but the toning qualities of the paper are of the utmost importance. I should not like to lay it down as an absolute fact, but I am inclined to believe that papers which do change colour slightly tone better than those that keep quite colourless. If this be really so, it would be well if the makers would pay a little less attention to the *appearance* of the paper and more to its toning properties."

Our Editorial Table.

LES RAYONS X.

By CH.-ED. GUILLAUME. Paris: Gauthier-Villars et Fils.

DR. GUILLAUME'S work is probably the completest that has yet appeared on the subject of the New Photography. In the first and second parts, light and many of its properties, electrolysis, and the varied phenomena of electrical discharges, are fully surveyed by way of introduction to the main theme of the book, which concerns itself with what has been done and discovered since the publication of Professor Röntgen's paper. Prominence is given to the recorded experiments of Continental workers, most of which we have noticed; but possibly the references to what has been done by experimentalists in this country might have been more numerous. The book, nevertheless, is very comprehensive.

NOTES ON ALUMINIUM AND ITS ALLOYS.

London: The British Aluminium Company, 9, Victoria-street, S.W.

THE history, physical and chemical properties, working particulars of melting and casting, forging, rolling, annealing, hardening, and other manipulations of metallic aluminium, are clearly detailed in this pamphlet of forty-two pages. It abounds in useful information regarding that most interesting of metals, which plays a by no means small part in the manufacture of photographic apparatus. The pamphlet is sent free, and is well worth sending for.

VELO-FYLMA.

F. R. Hinkins, Royston, Herts.

VELO-FYLMA is a quick-drying lac varnish for cold application to films, negatives, slides, or prints. It is recommended to apply it with a camel's-hair brush moderately charged with the liquid. So used, it answers extremely well, and dries rapidly. It is capable of being employed for a variety of purposes where a quick-drying varnish is a desideratum, and appears to have been carefully prepared, "no acid, alkali, minerals, celluloid, indiarubber, or borax," entering into its composition. Mr. Fallowfield is the wholesale agent.

PHOTOGRAPHY FOR ARTISTS.

By HECTOR MACLEAN. Bradford: Percy Lund & Co.

THE sub-title of Mr. Maclean's book indicates its scope. It essays to give "brief and useful information respecting the many uses of photography in various walks of the pictorial and allied arts." We may say at once that the information is well calculated to be of help to those for whom it is intended. A preliminary chapter discusses the great extent to which photography is availed of by artists, and is followed by one which very fully enumerates the classes of pictorial art in which photography is useful for supplying studies. Somewhat argumentative chapters on photographic falsities, from the point of view of an artist, and the photographic misrepresentation of tones, are included, but the photographic information for the guidance of artists taking up the camera has been well and judiciously selected. Notes on reproduction processes, the preparation of illustrations for reproduction, and a very valuable condensed list of photographers of whom photographs for artists may be obtained, add special utility to the book, which is full of sound hints and advice to artists employing photography. There are a number of explanatory illustrations.

CATALOGUES RECEIVED.

LIST OF STEREOSCOPIC VIEWS.

A. Seaman & Sons, Chesterfield.

WE preserve a soft corner in our heart for stereoscopic work, and are glad to receive Messrs. Seaman's list, which deals with about 1400 subjects of well-known spots of picturesqueness in London and various parts of the country.

William Hume, 1, Lothian-street, Edinburgh.

MR. HUME'S catalogue is a well-compiled publication. He caters specially for Röntgen ray work, thereby showing his enterprise, listing complete experimental outfits from 4*l.* to 37*l.* 5*s.*, and all the other accessories demanded by the New Photography. The remainder of the catalogue concerns itself with a lavish selection of photographic apparatus of all kinds, and prominence is accorded to the well-known cantilever enlarging system, which is Mr. Hume's speciality. This catalogue is the compilation of a man who thoroughly knows his business.

HALF-TONE ON THE AMERICAN BASIS.

By W. GRONENBERG. Bradford: Percy Lund & Co.

THE translation of this book, from the German, has been entrusted to the competent care of Mr. Gamble, and the result is a clear and fairly complete treatise on half-tone work, as it is said to be practised in America. The differences between the English and the American bases do not appear to be vital; but the work strikes us as being especially valuable on account of the fulness with which it treats of the apparatus employed, in which respect it has the advantage of other books on half-tone that we have read.

THE BARNET EXTRA-RAPID CUT FILMS.

Elliott & Son, Barnet, N.

THERE appears on the part of the makers of sensitive preparations a determination to give celluloid, as a support for the film of gelatino-bromide, every chance of securing a permanent share of photographic patronage. Messrs. Elliott, of Barnet, are laudably striving towards this end, and, judging by the sample of their Extra-rapid Films we have just tried, they are in a fair way to reach it. These films remain quite flat in an ordinary dark slide; they are very rapid without being unmanageably so, and the quality of the developed deposit is singularly fine and bright. Altogether a well and carefully prepared film.

News and Notes.

ROYAL PHOTOGRAPHIC SOCIETY.—Technical Meeting, Tuesday, May 26, at eight p.m. *Apparatus for Photography on Small Plates (smaller than Quarter-plates).*

THE PHOTOGRAPHIC CLUB.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, May 27. Mr. Frank Haes will demonstrate the *Daguerreotype Process.* Visitors will be welcome.

SOLDERS FOR GLASS.—The *Pottery Gazette* describes several metallic solders for glass, proposed by Mr. Charles Margot. The first is an alloy composed of ninety-five parts of tin and five of zinc, which melts at 200°, and becomes firmly adherent to glass. Moreover, it is unalterable, and possesses a beautiful metallic lustre. Another alloy, for the same purpose, is composed of ninety parts of tin and ten of aluminium, melts at 390°, is strongly soldered to glass, and is possessed of a very stable brilliancy. With these two alloys it is declared to be possible to solder glass as easily as to solder two pieces of metal. The operation is as follows: The two pieces of glass to be soldered can either be heated in a furnace, and their surfaces rubbed with a rod of the solder, when the alloy, as it flows, can be evenly distributed with a tampon of paper or a strip of aluminium, or an ordinary soldering-iron can be used for melting the solder. In either case, it only remains to unite the two pieces of glass, and press them strongly against each other, and allow them to cool slowly.

SOLIDIFIED GELATINE.—Gelatine possesses the curious property of becoming insoluble in contact with formic aldehyde, and, at the same time, of preserving perfect transparency. Gelatine rendered insoluble, or "petrified," to use a more appropriate term, resists water, acids, and alkalies. It resembles celluloid, but has the great advantage over the latter of not being inflammable. The gelatine used is the ordinary article found in commerce. The formic aldehyde is what is commonly called "formol," "formaline," and "tannaline." The commercial product is a forty per cent. solution of formic aldehyde in water. It is a colourless, syrupy liquid of a pungent odour. The vapour is not inflammable, and it is a powerful antiseptic. To obtain moulds of statuettes, &c., take two pounds of good white gelatine, and steep it in a quart of water for a night. The next day the whole is melted over a water bath. For delicate mouldings, the solution is diluted with a little water. The mould, which may be made of plaster, clay, or metal, having been prepared, the formic aldehyde is poured into the melted and slightly cooled gelatine. The whole is well stirred with a wooden spatula to obtain a homogeneous mixture. The latter is then poured into the mould and allowed to cool. After the object is taken from the mould, it is finished by immersing it for a few moments in a concentrated solution of formic aldehyde, or, if it is too large for immersion in the solution, its surface is painted therewith. Objects obtained with the gelatine alone are transparent, and resemble glass. However, by previously adding to the gelatine some finely sifted zinc white, mixed with a little water and alcohol, and operating in the same way, beautiful imitations of white marble may be obtained. By mixing the oxide of zinc with appropriate colours, objects of all shades may be obtained, and, by properly arranging the colours, veins, striæ, spots, &c., may likewise be produced. The solidified gelatine may be used for imitating mother-of-pearl, tortoise-shell, amber, coral, &c., and for the manufactnre of toys and artificial flowers. —*Scientific American.*

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

May.	Name of Society.	Subject.
25	Borough Polytechnic	Excursion: Windsor and Virginia Water.
25	Croydon Microscopical	Excursion: West Hoathly. Leader, Dr. H F. Parsons.
25	Hackney	Excursion: Pallborough.
25	North Middlesex	Excursion: Billericay.
26	Hackney	*Development.* R. Beckett.
26	Royal Photographic Society	Apparatus for Photography on Small Plates (smaller than Quarter plates).
27	Photographic Clnb	*The Daguerreotype Process.* Frank Haes.
28	Ireland	Annnal Meeting.
28	London and Provincial	*Washing Silver Prints without Running Water.* A. Haddon and F. Grundy.
28	Oldham	*Photographic Printing Processes.* T. W. Hilton.
30	Birmingham Photo. Society	Excursinn: Sntton Park. Leader, W. T. Greathatch.—Last Day for Sending in Competitive Prints for April Excursions.
30	Borough Polytechnic	Visit to British Mnsenm.

30	Leytonstone	Exc.: Crayford. Leader, U. Andrews.

ROYAL PHOTOGRAPHIC SOCIETY.

MAY 19,—Photo-mechanical Meeting, the Earl of Crawford, K.T., in the chair.

Mr. T. BOLAS called attention to a reference, in Robert Hunt's *Researches on Light*, to the theory of invisible radiations, and also to the experiments of Reichenbach with regard to the asserted

LUMINOSITY OF MAGNETS,

in which the effect was tried of the magnetic rays on the Daguerreotype plate.

The CHAIRMAN said Reichenbach's experiments followed those of Dr. Olynthus Gregory, of Edinburgh, the author of a work on odic force. Reichenbach ascertained that many people were able to find magnets in the dark, provided the poles were open, when a different coloured light emanated from each pole. These experiments were carried into the electro-magnetic period, when the light apparently grew considerably in height, but not much in breadth. Lord Crawford said he had made a great number of attempts to photograph these emanations, but without success, and had also found that many persons were able to indicate the precise spot upon which a magnet had been deposited in a dark room. If a magnet or a piece of rock crystal were brought near one's forehead, almost any one could feel its approach, even though the object had previously been raised to the temperature of the body. People who could see a magnet in the dark generally described its appearance as "lambent," which probably meant that it gave off a light something like that of bad fish.

Mr. BOLAS remarked that persons differed very much with regard to capability of perceiving slight radiations. Some people could, on a dark night, gather earth-worms for fish bait in consequence of the slight phosphorescence of the worms.

Mr. WILMER suggested that the discovery of a magnet in the dark might be due to some cause other than light, such as electrical radiations; but

The CHAIRMAN did not think this was the case.

Mr. SNOWDEN WARD said Mr. Brooks had made experiments with regard to the photography of magnetic radiations, and, as the subject was of considerable interest, he might be induced to read a paper thereon, and to bring his results before the Society. Mr. Ward thought that Mr. Brooks had investigated the effect of human emanations, which were said to be similar to magnetic effects.

Mr. BOLAS showed an original print of an advertisement issued by Mr. Cowderoy, of Reading, as an inset to the *Art Union Monthly Journal* of July, 1846, respecting the granting of licences to work the Talbotype process, and referring to the application of photography to many purposes to which it had since been adapted. It was arranged that the leaflet, as possessing some historical interest, should be pasted in the Society's copy of Talbot's *Pencil of Nature.*

Mr. IGNATZ HERBST had been announced to read a paper on *Photo-mechanical Methods in Austria*, but he said that since he left that country the introduction of Levy's screens had so changed the course of procedure that he did not propose to deal with that subject. He showed instead a number of negatives and blocks illustrating his method of working in London, particularly with regard to the production of

HALF-TONE ZINC BLOCKS.

So far as could be gathered from his remarks, he recommended a ground of bichromated albumen, the resist being formed of—

Ethereal extract of gamboge	20	grammes.
Turmeric	20	,,
Olive oil	10	,,
Benzole	50	,,
Heavy coal tar naphtha	20	,,
Chloroform	150	,,

He used square stops of two sizes in exposure, giving about seven minutes with a small stop and an additional minute with a larger one, the stops being inserted in such a position that their sides were across the lines of the screen. Mr. Herbert also spoke of photo-lithography in half-tone, and showed samples of Hubl's collodion emulsion for three-colour work, but we regret to say that his knowledge of the English language was not quite sufficient to enable his hearers to fully grasp the valnable information which he endeavoured to convey.

In the course of a conversation which ensued, some discussion took place upon the favourite question as to the origin of "devils," the CHAIRMAN suggesting that they might be due to the deposition upon the plate of meteoric iron in the shape of impalpable dust.

Dr. Lindsay Johnson passed round one of a series of pamphlets by himself, entitled *Observations on the Macula lutea*, containing reproductiona by Mr. Herbst of micrographs of sections of the retina, the degrees of enlargement varying from fifty to 5000 diameters. From the original negatives prints had been made on Nikko paper, from which fresh negatives were made through screens of 175 lines to an inch, and prints from the blocks were very carefully made on fine paper, and pasted into the text of the pamphlet.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 14,—Mr. J. Packham in the chair.

The HON. SECRETARY passed round for signature a form of petition to the railway companies of Great Britain and Ireland, asking for a reduction in fares to photographers, which had been issued by a contemporary. With reference to the support they had promised to the Gospel Oak Photographic Society, in their appeal to the London County Council to confine their gardening operations to certain portions of Hampstead Heath, he had been advised that the best means of furthering this aim would be to pass a similar resolution, and forward same to the Council and the vestries as a separate appeal, and recommended that this be done.

A similarly worded resolution was therefore proposed by Mr. FRESHWATER, seconded by Mr. WALL, and carried unanimously.

Mr. Freshwater exhibited a shadowgraph of live frogs, which had not been chloroformed, as usnally done. Exposure was complete in ten seconds.

Mr. ASHBY read a paper on

PHOTO-MICROSCOPY.

Many, he said, regarded the microscope as a mere toy, and its study a passing

enjoyment, but he knew members of the London and Provincial were not so flippant. It was an immense subject, and the application of photography to the microscope opened up a large and interesting field. Objects required very careful lighting, as in the majority of cases the light passed right through, and was not reflected, as in ordinary photography. They should be mounted as flat as possible, so as to get everything sharp. In ordinary photography the different planes are brought into focus by stopping down, but, by keeping the sections, &c., as flat as possible, the loss of light so caused is avoided. There is a temptation to use too much light, but what is necessary is an intense light under perfect control. Sunlight may be used as the illuminant, but most people are debarred from its use on account of the indispensable heliostat and expense. He found a good paraffin lamp, with round wick, all that he desired. Some people advocated the use of the edge of the wick as the source of light, but he preferred a round wick. The addition of a little camphor to the oil increases the whiteness of the light. The apparatus is simple enough, and consists of a long extension camera (that used by Mr. Ashby being of his own construction throughout), fitted with a microscope, capable of adjustment in all directions, and the lamp, all being placed on one baseboard, which folded up when out of use. He used two focussing screens, one of ground glass, and another of plain glass for fine definition, the image on the latter, however, not being visible without the aid of an eyepiece. The first and great essential is that everything should be centered perfectly, or failure would be certain. The size of the diaphragm was more or less controlled by the objective in use, and would be learned by practice. Orthochromatic plates should always be used, and should be developed rather dense. He preferred a pyro-soda developer to any other for the work. Some sections and other objects were then focussed on the ground glass and shown.

The CHAIRMAN thought the sight of the apparatus necessary, for the pursuit of this subject startled a good many, but he said it was a simple thing to get very fair pictures without the costly apparatus and beautiful degree of adjustment seen. He had found, in practice, an immense advantage in the use of a yellow screen.

Mr. FRESHWATER, referring to the photographing of opaque objects, said it was most interesting, and one got a photograph of the object itself. Light-coloured subjects were pretty easily illuminated, not absorbing much light, but with dark objects it was more difficult. He recommended the use of iris diaphragms for cutting down the light.

Mr. HODD asked if a process screen could be used for focussing?

Mr. WALL replied that the lines were too close, but one with about twenty lines to the inch would do. Speaking of Mr. Ashby's preference for a round wick, he asked if he liked it better than the edge for high-power work? He always used the edge, as he had found a loss of definition with flat or round wicks. He was in the habit of using a very large diaphragm, cutting down with coloured screens, such as signal green, or a chromate of copper liquid screen. These, however, can only be used for some subjects. One great difficulty with beginners was to know when everything was correct and in sharp focus.

Mr. ASHBY thought the light better for its yellow tint, except when using high powers, when great brilliancy is required.

Mr. FRESHWATER agreed with Mr. Wall that a number of coloured screens were very convenient.

Mr. ASHBY, in answer to a question, said his lenses were not specially corrected for photographing.

Mr. WALL had used monochromatic light a good deal, but there was a great loss of illumination, and it was somewhat expensive. For photographing, a small source of light was needed, but for examination he preferred a large quantity of light. The chromate of copper screen mentioned before cuts out the violet, but the amount rested with the thickness of the screen. He thought the binocular microscope provided for the examination of the slides infinitely better than a monocular.

A number of slides were then thrown on the lantern screen by Mr. Ashby and the Chairman, consisting of botanical and anatomical subjects, which were highly appreciated, and the Chairman also displayed some taken with low powers by the simple apparatus which he had used with much success.

PHOTOGRAPHIC CLUB.

MAY 13,—Mr. Nesbitt in the chair.

A letter was read from the Secretary of the Gospel Oak Photographic Society, inviting the Club to co-operate with it in protesting against the alterations which the London County Council is making on Hampstead Heath.

It was pointed out by Mr. WILLMER, however, that, as the Gospel Oak Society's first protest had taken place some considerable time ago, it was more than probable the Council had already made the alterations to which objections might be taken, or, in the alternative, had made such arrangements as would make protest of no practical avail.

Several of the members, however, expressed their willingness to join the Gospel Oak Society in protesting against anything done by the London County Council which would have the effect of spoiling the natural beauty of the Heath.

Mr. Lambert Matthews, who attended on behalf of the Scientific Hand Camera Company, showed an example of the Company's new scientific hand camera. This is of the twin-lens pattern, the photographer having a full-sized image of the picture he is about to photograph visible at the moment of exposure. The Company fits Wray's (or any other maker's) lenses to order, and supplies either the ordinary double backs, or a Pullman magazine back. The camera, which is of exceedingly compact design, was examined with a great deal of interest, and Mr. Matthews was thanked for showing it.

Mr. Golteur showed one of Marion's plate-separators. These are made of celluloid, and can be used for separating and holding in position in the developing dish either two quarter-plates in a half-plate dish, or four quarter-plates in a whole-plate dish. The simplicity and utility of the device is obvious.

The editor of the Club's *Transactions* drew attention to a letter from Mr. Cadett, referring to a recent editorial comment upon the published report of the Club's meetings.

Some conversation ensued, and Mr. BRIDGE added to Mr. Cadett's previous remarks upon the idiosyncrasies of pyrogallic acid as regards speed the following: He said he had recently been working a sample of pyrogallic acid, which differed from previous samples by the same maker to the extent that it only required one-half the amount of pyro to produce normal density.

Mr. W. D. WELFORD read a short paper upon the

PRODUCTION OF UNSUCCESSFUL PHOTOGRAPHS

in a manner quite his own. The paper told the members of the Club exactly how "not to do it." It was written in a sarcastic vein, and will probably appear in full in the proceedings of the Erratic Club.

MANCHESTER PHOTOGRAPHIC SOCIETY.

MAY 14,—the President (Mr. H. M. Whitefield) in the chair.

The PRESIDENT mentioned that, as the present rooms were not available for the summer meetings, the Society would hold them out of doors at some place convenient to Manchester, on the second Saturday in each month.

Mr. A. E. Casson exhibited a hand camera by Miller, which he has had made to his order. The size of plate is 5×4, and is exposed in dark slides; there is an adjustable focussing screen, enabling the camera to be used on the stand. It has a Goerz six-inch lens, Thornton-Pickard shutter, and detachable finder, the whole being most perfectly made and compact.

The business of the meeting was then proceeded with, Mr. HARRY WADE reading a paper on the

HOME PREPARATION AND MANIPULATION OF PLAIN-SURFACE SILVER PAPER.

Mr. Wade did not lay any claim to originality in regard to the preparation of the paper, which is by old formulæ revived and verified by actual experiment. Twenty years ago, every photographer made the preparation of sensitised paper his special study, and knew the theory as well as the practice of what he was using; but, in these days of trade production, photography is reduced to such extreme simplicity, that one has only to follow blindly the printed instructions to obtain certain results. But, to be able to vary these results at will, it is necessary to have at least some elementary knowledge of the materials in which we are working, and, in view of encouraging a thirst for knowledge, a few notes may not be out of place to exhume this beautiful but lost art of silver printing. Mr. Wade then gave a short description of the action of light on silver compounds, afterwards proceeding with the preparation of the paper. For small work, a smooth photographic paper, such as Saxes or Rives, is the most suitable, while, for anything above cabinet, Whatman's drawing papers are the best. Sizing and salting can be done simultaneously, the formula being—

Ammonium chloride	160 grains.
Gelatine	240 ,,
Water	20 ounces.

Immerse the paper bodily in the warm solution, then hang up to dry; a quantity can be prepared, for it keeps indefinitely. The paper is now ready for sensitising, which can either be done by brushing or floating. The strength of bath should be sixty grains to the ounce; it can either be the ammonia-nitrate bath or an acid bath, the ammonia being made up by adding ·880 ammonia to the silver solution till the precipitate first formed disappears. The paper so sensitised prints richer, but fails to keep more than a few days. The acid bath is made by adding twenty-three grains of citric acid to each ounce of solution, in which case the paper will keep for a much longer period. The paper should be floated twice, in order to leave no places unsensitised. The paper, after printing, should be well washed in several changes, in order to free it from all nitrate, and then toned in sulphocyanide, acetate, tunsgate, phosphate, borax, or chalk gold bath, the combined toning and fixing as recommended for Alpha paper and platinum, and fixed, washed, and mounted as usual.

After the paper, Mr. Wade gave a complete demonstration of his method, from salting the paper to fixing the prints, in which the members were greatly interested.

Croydon Camera Club.—A party of members, in charge of Mr. Hector Maclean (the President of the Club), spent

HALF A DAY WITH MR. A. R. DRESSER,

at Springfield, on Saturday, May 16. With characteristic energy and kindness, Mr. Dresser rose from a bed of illness in order to entertain his visitors, which he did in such fashion as to give very great pleasure to those who were fortunate enough to be present. A chatty lecturette, relieved by startling anecdotes, and accompanied by demonstrations of the uses of various more or less unique pieces of apparatus, was introductory to a personally conducted tour of the house, many of the numerous art objects, curiosities, and photographs calling forth remarks from the host which were reminiscent, descriptive, or laudatory. During the afternoon, Mr. Wratten took the usual recording photograph of the Club excursion. Mr. Andrew Pringle, who happened to be present, was, *pro tem.*, elected an honorary member of the Club, and included in the group, into which Mr. Dresser took the opportunity of pouring in a number of "*Bullet*" shots.

Hackney Photographic Society.—May 12, Mr. William Rawlings presiding.—Members' work was shown by Messrs. Roofe, Westcott, and Hindsley. Mr. Cricks, of Messrs. Whittingham & Co., showed a number of very ingenious new hand cameras and accessories. The Hon. Secretary showed some examples of colour rendering by Lumière's orthochromatic plates. The principal attraction of the evening was a lantern lecture by Mr. E. T. COOMBES, entitled

A CYCLING TOUR WITH A CAMERA.

It proved to be a most interesting one, and was illustrated by some very good slides. The following particulars are to hand of the proposed excursion to Pulborough on Whit Monday: A permit has been obtained for the party to go by the 8.40 a.m. special Portsmouth train from London Bridge, London, Brighton, and South Coast Railway. To avail themselves of it, members intending to go must meet the Excursion Secretary (Mr. Dean) before passing the barrier.

North Middlesex Photographic Society.—May 11, Mr. Pither in the chair.—Mr. DEBENHAM gave a paper on

PERSPECTIVE.

He said that, among the reproaches brought against photography, that one which is perhaps the most surprising is that of rendering objects untruly as to perspective. He confined himself to dealing with linear perspective. He showed a slide in which a series of globes extended along the top the entire width, with a background of ruled squares, the globes near the corners appearing as ellipses. Although the eye never sees a globe as an ellipse, it would appear so if the eye were fixed at the point from which the photograph was taken. He also showed two slides of a man holding out one hand in front, and the other behind him, taken with a long and short-focus lens respectively. The marked difference between the size of the hands in the photo taken with the short-focus lens was very apparent. At the close of the lecture the CHAIRMAN said that the whole matter of true and false perspective in photography might be summed up by bearing in mind that the retina was a concave plane, and the plate a right plane. Among those who joined in the discussion was Mr. TILNEY, an artist, who said he knew very little about perspective, and his opinion was that the whole duty of an artist was to paint things as he sees them. You cannot see a sphere but as a sphere, because the eye has to move to see it. The eye shifts its point of sight many times a second to take in a view. Artists have nothing to fear from photography, but it has taught them a good deal.

MAY 19, Instruction Evening, Mr. H. Smith in the chair.—The HON. SECRETARY gave a demonstration on

INTENSIFICATION AND REDUCTION.

He gave various formulæ, and passed round various examples, to illustrate his remarks. He then proceeded to intensify a plate by the following formulæ:—I. Silver nitrate, 22 parts; water, 250 parts. II. Potassium bromide, 10 parts; water, 25 parts. Mix and wash precipitate of bromide of silver, and dissolve in hypo, 60 parts; water, 170 parts. Make up the whole to 450 parts. Immerse negative in this for several minutes, and place in a ferrous-oxalate developer (Wall's Dictionary). He also intensified a plate with bichloride of mercury, followed by cyanide of silver. For reduction, he used Howard Farmer's and Belitski's formulæ, and passed round the plates for inspection. The next Instruction Evening will be on June 15, when Mr. W. J. Simpson will demonstrate silver printing and toning.

Aintree Photographic Society.—The second excursion of the season arranged by this Society took place on Saturday, May 16, to Knowsley Hall (by permission of Lord Derby). Several of the ladies were invited to inspect various rooms of the Hall, the camera men having a busy hour and a half in the grounds. About ninety plates were used upon the Hall, avenues, sundials, cattle, &c. The large trees of hawthorns and varied-coloured rhododendrons in full bloom were quite a sight. The party of thirty-nine had a most enjoyable day.

Leeds Photographic Society.—May 7, Mr. J. H. Walker (Vice-President) in the chair.—Mr. ALFRED NAYLOR (the Hon. Secretary) introduced the subject of

PAPER, STRIPPING FILM, AND CELLULOID FILM NEGATIVES,

briefly stating the reasons which induced him to take up this portable form of working, and showing between 200 and 300 negatives, taken during the last nine years, these, with three or four exceptions, having been exposed in the Eastman roller slide. Considerable interest was taken in this unique collection of negatives, which represented both local and distant work (within Great Britain), and favourable comments passed on the perfection of several of them, which were acknowledged to be equal to wet-plate negatives. At some future date Mr. Naylor proposes devoting a full evening to this subject, showing the working of the latest apparatus in connexion therewith. An Aphis hand camera, which has been forwarded for inspection, was very favourably received.

Oxford Camera Club.—May 11.—After some arrangements for an Exhibition to be held in the autumn had been discussed, the decision being postponed till next meeting, a demonstration of

PLATINOTYPE

was given by Mr. T. H. STRINGER, of the Platinotype Company. The whole process was thoroughly illustrated, and its advantages pointed out, both as to artistic effect and permanency. As showing permanency, the lecturer mentioned a case of platinotype prints undamaged after three weeks under sea water in a sunken ship. The lecturer also showed how, especially in large prints, development could be done with perfect success by means of a brush, if development were restrained by the addition of glycerine. By rubbing certain parts with pure glycerine they could be kept back, while others, if desired, could be brought up quickly by unrestrained developer. A very hearty vote of thanks to Mr. Stringer was passed by acclamation, the audience, though not large, having been very much interested, and much admiring the ease of the process and beauty of the results obtained.

"COSMOS" AND MR. FRY.

WE are sorry that in the JOURNAL of last week, under the heading "Jottings," the authorship of some paragraphs (that had appeared in a contemporary) signed "Major Kone," was erroneously attributed to Mr. S. Herbert Fry, who denies identity with, or knowledge of, the writer. Mr. Fry further complains of the term "slipshod" being applied to his trading, and we hasten to say that the term was wrongly applied.

We are convinced that the references to Mr. Fry were not designed to be of a harmful or offensive nature, but we are sorry they were allowed to appear, and, in taking this, the earliest, opportunity of giving publicity to Mr. Fry's denial and protest, we desire to add that, in unreservedly accepting his statement, we regret the insertion, and offer him our sincere apology for the mistaken introduction of his name.

Correspondence.

☛ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

BROMIDE PAPER FOR NEGATIVES.

To the EDITORS.

GENTLEMEN,—Last year there were several letters and articles in the JOURNAL *re* paper negatives, and doubtless many of your readers, on seeing that Messrs. Wellington were about to introduce a paper for this purpose supposed that this demand was to be supplied. But, although, doubtless, very good as far as quality and convenience goes, the article this firm introduced is not at all what was wanted.

The principal reason paper negatives were advocated was the reduction in cost. 12 × 10 bromide paper sells at 4*s.* per dozen, and what was required was a negative paper at same price. Why should it not be supplied? Why should a positive paper be 4*s.*, a negative 14*s.* per dozen? If it could be, many amateurs would work it in a home-made camera, with a "pinhole" lens, which would give fair definition for that size picture. Further, would it not be possible, by using a chocolate-coloured paper and whitening the image with mercury, to produce a "positive" ready for framing?

Another item: Some months ago a correspondent from India, I believe, offered to communicate a method of stripping P.O.P. on to glass, or any other material required; if he would send same, I, for one, should feel obliged, doubtless many others.—I am, yours, &c., W. R. F.

FLUORESCENCE OF GELATINE DRY PLATES.

To the EDITORS.

GENTLEMEN,—When experimenting with X rays on the 11th inst., I found that a Paget XXXXX plate was markedly fluorescent to the rays. I was able to see clearly coins in a purse, nails in wood, and, faintly, the bones of my hands and fingers when placed between the tube and the plate with the film side of plate towards the tube, and all external light absolutely excluded. As this opened up what was to me a new line of experiment, I tried several experiments, unsuccessfully at first, but afterwards successfully, to find if fluorescence was visible with plain glass. On ground glass fluorescence was quite visible, and, although faintly, I saw it on ordinary lantern-slide covers. When I scraped a portion of the film off a Paget XXXXX plate or an Ilford plate, although the fluorescence was very much more decided on the coated portion, I could still see the coins in a purse on the clear glass portion when interposed between the tube and the negative.

I am satisfied that fluorescence of the sensitive film as well as of the glass takes place, but I have not had time to verify the experiments I wished to carry out, owing to the failure of two tubes, one after another, which I was working with.

I found a red half-plate vignetting glass with clear portion in the centre fluoresced all over when the red coloured side was towards the tube; but, when the red side was towards me, only the central clear portion fluoresced, indicating that the fluorescence was on the side towards the tube, and that the red glass, when next myself, cut off the luminous effect, except in the centre. A piece of ordinary red glass acted the same way, viz, one side fluoresced and the other did not. I failed to detect visible fluorescence with celluloid films or bromide paper, and I found that most crystals, when deposited on only a lantern slide cover, increased the visible fluorescent effect, such, for instance, as bromide of ammonium and pyrogallic acid. When the latter was put on a white card I could detect no fluorescence, and came to the conclusion that the crystals were increasing the visible fluorescence by providing the glass with a white reflecting background. I found ordinary luminous paint on a card makes a very fair screen, but not nearly so bright as scheelite or potassium or barium platino-cyanide.

I am aware that the appearance which some plates are said to present of the image coming up from the back of the plate during development has led some people to infer that the action of the X rays is at the back of the film. I have developed many X ray photographs, and have not found the image come up from the back on Paget XXXXX plates, which I generally use, and I hope some of your correspondents will repeat and extend the experiments which I have referred to, as the subject is one on which some light may be obtained by experiments in this direction.—I am, yours, &c., W. P. WALKER.

Glenbanna, Laurencetown, Co. Down, May 16, 1896.

BRADFORD PHOTOGRAPHIC SOCIETY.

To the EDITORS.

GENTLEMEN,—As a good example of the kind of report a piqued Secretary can write, the report published in your paper of May 8 would be bad to beat. The official mostly alluded to was the person who started the Society, and who retired because of the attitude taken up by the Secretary, and who was the "knowing member" alluded to by your

correspondent. The said "knowing one" has been the means of exposing two or three pieces of very sharp practice in the affairs of the Society, and in a small circle of the Committee was rather "loved" a long way off. He treated the members to a short speech touching the affairs of other societies, and he finally "dried up" when he had got all his rules passed and what he desired, and was then elected a Vice-President by the meeting. This is very contrary to the impression that would be created by a stranger reading the report, and it seems a great pity that a Secretary should so have reported the proceedings.—I am, yours, &c.,

May 18, 1896. A MEMBER OF THE LATE COMMITTEE.

P.S.—Nearly all the new Committee were elected from the co-called opposition party.

CARDIFF PHOTOGRAPHIC EXHIBITION.

To the EDITORS.

GENTLEMEN,—As an old photographer, I should like to say a few words concerning the management of the Photographic Exhibition now being held at Cardiff. On the occasion of my visit, passing through the large hall of the Maritime Section, I came across the exhibit of a great engineering firm from the north. The manager of the same, recognising me as one who had done a deal of work for them in past years, suggested that I should photograph their exhibit. Judge of my surprise on finding, that the right to photograph was vested in the local Society (almost essentially an amateur one) who are also running a portrait studio in the grounds, and thus entering into direct opposition to the professional photographer.

I should imagine that, in the future, members of the photographic profession will be very chary of supporting any Exhibition produced "under the auspices of the Cardiff Photographic Society."—*Vide* ADVERTISEMENT.—I am, yours, &c., THE KAISER.

Cardiff, May 18, 1896.

To the EDITORS.

GENTLEMEN,—In your report of the Photographic Section of our Cardiff Fine Art and Industrial Exhibition you do not appear to have ascertained the fact that it was not all glory that these few members of the Photographic Society were working so hard for, they having formed themselves into a syndicate to work two studios in the Exhibition, also the right of photographing exhibits—concessions granted to them by the Executive Committee of the Fine Art and Industrial Exhibition for getting together the Photographic Exhibition; also, as far as I can understand, 1*s.* on each season ticket, the holder of which has to have a portrait on the inside. There has been up to now nearly 3000 issued. The amateurs are certainly up and doing. Professionals will have to look alive.—I am, yours, &c.,

12, *Duke-street, Cardiff, May* 12, 1896. ALFRED FREKE.

MONS. JARCHY'S BABY SHOW.

To the EDITORS.

GENTLEMEN,—As Mons. Jarchy of Union-road, Rotherhithe, seems anxious to satisfy me as to when the Baby Show and prizes are to be awarded, I herewith take the pleasure of appending my name and address. I should also like Mons. Jarchy not to send any reply to my address, same as he did once before, but reply in a straightforward manner through your JOURNAL, so that the public may have some idea of when the nicest-looking babies are going to be brought before the competent Judge and Jury, and medals pinned on their dress.—I am, yours, &c.,

62, *Eugenia-road, Rotherhithe, S.E.* W. H. HILL.

To the EDITORS.

GENTLEMEN,—You were good enough to forward me a letter addressed to me, under your care, by Mons. Jarchy; possibly you may deem it interesting enough for publication.—I am, yours, &c., COSMOS.

London, May 19, 1896.

45, *Union-road, Rotherhithe, London, S.E.*
May 17, 1896.

TO MR. COSMOS.

DEAR SIR,—I was highly delighted to read in the last week's "Jottings" your very witty note comparing me with C. J. Rhodes, Esq. I hope, Mr. Cosmos, it is not intended as a compliment, as, truly, I should very much like to be in his shoes.

What surprised me is that my letter adressed to the *concealed individual* has been answered by you, and in a rather irritable and sarcastic manner!

In fact, it is strange for a Son of Momus to be partial or get angry with me who never adressed you a word and whom you never saw. And you leave the part of a neutral and impartial judge of facts in associating yourself with the man behind the coulisse. It looks to me too personal. "Est-ce vrai?"

Now, Mr. Cosmos, let us come to an understanding:

A note appeared in the "Ex Cathedâ" a fortnight or so ago, where a complaint has been mentioned from a South East correspondent for not carrying out my promise of a Baby Show, etc., etc. And you were kind enough to put your paper at my disposal to satistie your correspondeut. I replied to the worthy correspondent, inviting him to divilgue his name as an accuser should do. "En plus," I threw my glove to his face, to which any gentleman would reply, but, instead, be coyly applied for your protection. Thanks to the X rayes, I can see his epistle:  and Ora pro Nobis."

"Fi donc!" Why should he be afraid to face the music and come up to the area of a fair battle? I am a son of Mars, and defy any sneaky quet-a-pens! What, is he afraid perhaps for a law suit—is it so?

I can promis you, Mr. Cosmos, that you will find very piquant material for your "Jottings," to last a year, if you will suggest your correspondent to disguise his masque.

I am very proud you detected in me a refined scruple. I was told so several times, and it is very hard to make me bite the bait.

So come, Mr. South correspondent, for the credit and glory of the spying industry, and show to our photographic world where you are, and what is it you wish from me. Or I may get another name in the life dictionnary in the form of a more stronger glove, perhaps, that will intimidate your appearence. "Je dis ce que je pense." I remain, yours, respectfully,

A. L. JARCHY.

ASSISTANTS AND THEIR GRIEVANCES.

To the EDITORS.

GENTLEMEN,—Your leading article of May 15 on the above subject should cause assistants to seriously consider their position, and, by coming forward to join the National Union of Shop Assistants, give proof that they have taken the sound advice you tender. Your remarks on the over-stocked state of the photographic labour market must be confirmed by all, though some may not agree with your deduction that it is due to the "little learning" now required in comparison with the days of collodion. My own opinion is that this excess of labour is caused by the rise of the specialist, the abuse of the apprentice system, and the facilities now offered for acquiring an insight into photography apart from the workshop. Photography has developed to such an extent since the wet-plate days that no man can possibly become an adept in all branches. The specialist is therefore a painful necessity. This change enables many to enter the trade who have a knowledge of only one minor part and have not the capacity to undertake highly skilled work. The trade is thus thrown open to a larger and inferior body of men. Going back, in my own experience of twenty years, I am compelled to admit that the average photographic worker of to-day is much the inferior of the man of that period. In spite, however, of the specialist with his "little learning," I think that skilled men are still in demand, but are not supplied. Take printing. A printer is now expected to work at least four different processes—albumen, gelatine, platinum, and carbon. In my wet-plate days the majority were content with Rive and Saxe albumen papers. I was lately told by an employer that, out of twenty-two applicants for a post as a printer, only two could fulfil these requirements, and he engaged and paid one of them double the salary asked by the remainder. "The rest," he added, with a sneer, "were Polytechnic photographers." This phrase, "Polytechnic photographer," has given me cause for reflection. It indicates clearly one cause of the over-stocking, and, when combined with the specialist and the bad training of apprentices, accounts in large measure for the great numbers of inefficient workmen clamouring for employment. Skill and wide knowledge are still in demand, but "little learning" and the consequent over-stocking carry the day, because, as I have often pointed out before, the photographic worker will not organize to protect himself. A well-organized trade is not likely to be over-stocked, because its members can regulate the number of apprentices, keep up a high standard of effciency, and in other ways make it difficult for those to practise the trade who have not had a practical training in the workshop.

Your statement that, photography being unlike the mechanical trades, the rate of wages cannot be regulated, seems open to question. Photography cannot be said to be less mechanical than lithography, yet the Union of Lithographic Artists, Designers, Writers, Draughtsmen, and Copperplate and Wood-engravers is a most flourishing society, and easily meets the wages question. All the regulation of wages desired is to fix a minimum rate for each branch. For instance, in photography this minimum might be fixed at 30*s.* for operators; but obviously this does not prevent a member from taking 5*l.* It must not be supposed that a Union would fix the minimum wage at 5*l.* when the average rate is only 30*s.* The rate is fixed, not from abstract principles of what ought to be paid, but by what is practically paid at the time by the fairest employers in the district. Thus, to pay spotters 12*s.* when 15*s.* is the wage paid by fair employers is a proceeding which a Union would oppose and would take means to protect its members against.

"Cosmos" states that those who are satisfied with their position will not join a Union. Experience proves that these are just the persons who do join Unions, not to improve their position, but to secure and maintain it. In fact, they are the backbone of every Union. It is the combination of the best workmen which gives the power to trade unionism that it exercises, and, the more uncertain and unstable the position of a workman, the more difficult it is to form any combination. Once organize the best workers, and the condition of all in the trade improves, even of those who have only a week between them and starvation; for it compels those who are not sufficiently skilled to demand the minimum wage to come up to that standard or quit the trade.

I again urge photographic assistants to join the National Union of Shop Assistants, 55 and 56, Chancery-lane, London, and combine for mutual protection.—I am, yours, &c., JOHN A. RANDALL.

18, *Canbury Park-road, Kingston-on-Thames.*

Patent News.

The following applications for Patents were made between May 6 and 13, 1896:—

Camera and Surveyor's Level.—No. 9493. "A Combined Photographic Camera and Surveyor's Level." E. Wood.

Burnishers.—No. 9510. "Improvements in or relating to Photographic Burnishers." Complete Specification. G. C. W. Gennert.

Wall Bracket for Photographs.—No. 9781. "An Improved Wall Bracket for Holding Photographs and other Pictures." W. J. Robinson.

Dish.—No. 9792. "A New Dish for Photographic and other Purposes." W. S. Wain.

Printing Frames.—No. 9799. "Improvements in Photographic Printing Frames." E. Marlow, jun., and T. Marlow.

Answers to Correspondents.

"*** *All matters intended for the text portion of this* Journal, *including queries, must be addressed to* "The Editors, The British Journal of Photography," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

"*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

"*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* Henry Greenwood & Co., 2, *York-street, Covent Garden, London.*

Photographs Registered:—

J. Ellis, 332, Great Alfred-street, Nottingham.—*Photograph of Bendigo, Champion of England.*

William Thompson, 126, Sydney-grove, Newcastle-on-Tyne.—*Photograph of Miss Menzies as "Galatea."*

Arthur Simmons, 25½, Westminster Bridge-road, S.E.—*Photograph of group of members of the Terriers' Association and friends.*

The Collodion Emulsion Company.—Optics. We have written the Company.

Defaulting Manager of Branch.—T. Hammond. Place the matter in the hands of the police at once.

Toning Solutions for Gelatino-chloride Paper.—A. C. H. Bell. The sulphocyanide toning bath you quote will suit all the papers named. Fix in a plain hypo solution.

Want of Sharpness.—M. Ferris. The print shows no fault in the lens; the lack of sharpness is due to movement of the camera during exposure. The image is doubled throughout.

Yellow Prints.—Hertford. The yellowness is due to the use of stale paper. If the paper has become yellow before it is printed, white prints must not be expected. There is no remedy with such discoloured paper.

Exposures—Ball and Trigger.—F. Tate. Opinions are divided on the subject, but the general opinion seems to be in favour of the pneumatic ball for stand cameras, and triggers or similar arrangements for hand cameras.

Printing.—S. E. K. J. If you depart entirely from the formula supplied with the paper, as you have done completely, it is not surprising that you do not get good results. In such circumstances it would be manifestly ridiculous to complain of the paper.

Developer.—C. Hardman. Distilled water is not necessary for the developer, though it is preferable. Failing a supply of distilled water, water that has been boiled for a time should be used. Boiled water is what is generally used for making the developing solution.

Damaged Roller.—Collotype. If the leather has several cuts upon it from the edges of the glass plates, there is no help for it but to have the roller re-covered. Why were the edges of the plates not ground, as is usually done, before using them? All instructions are to that effect.

X. Rays.—W. A. R. The print sent is interesting, but it is not anything like so good as those now made with the improved tubes, and a good induction coil. Influence machines, such as the Wimshurst, can be used, as your example shows, but in a damp atmosphere, such as we generally get in this country, they are very uncertain in action.

Stained Negative.—Cloudy. The stain is due to the liberation of sulphur in the film. After the treatment the negative has been subjected to, we suspect the stain cannot be removed. You say you are "afraid the stain will interfere with the printing." Why not try a print and see if it does? We should doubt it, except that it will require more time.

Bad Hyposulphite.—R. C. B. says: "I have bought fourteen pounds of hyposulphite of soda of a druggist here, who has gone in for cheap photographic goods and chemicals, the cheapness of which is made a feature of. After I had had the stuff a few days, it got quite wet, and the bag fell to pieces. It also has an unpleasant smell, quite unlike any I have had before. Some of the crystals are also yellow. Will it have any harmful effect on prints fixed with it?"—It is evidently a very impure article and unfit for photographic purposes. We should not think of using such a sample ourselves.

Wet Collodion.—T. Childes. The developers, whether iron or pyro, as used for gelatine plates, cannot be used for wet collodion. The formulæ, both for the developer and the intensifying solutions, are quite correct. Persevere, and you will succeed in the end.

Spots on Negatives.—J. Landor writes: "Will you have the goodness to examine negative I send herewith. You will find it has a number of brown spots dotted here and there over the film, and it is on the subject of these spots that I ask your advice. I have suffered with this photographic measles for about eighteen months now, and have tried everything I can think of to prevent their appearance. I notice them more particularly when a fresh fixing bath is made up."—The spots are caused by the presence of iron in the water or in the hypo. If fresh samples of both are used, the spots will doubtless not appear.

Lens for Hand Camera.—J. Wade says: "I have a hand camera fitted with a lens of five and a half inches focus, but it does not include, on the quarter-plate so wide an angle as I should like to take in the pictures. I think of having another lens of three inches and three-quarters focus. Would that not take in a much wider angle of view, and be equally as quick as the other, as both are said to work at *f*-8?"—Yes. The shorter-focus lens would include a much wider angle than the other, and it will be equal to it in rapidity, but it must not be expected to cover the quarter-plate with the same aperture as the longer-focus one. It will require stopping down considerably to do the work properly; then it will become necessarily a slow lens.

Sensitising Bath.—One in Difficulty says: "1. I have had some trouble with my nitrate of silver bath, which I use for sensitising albumen paper on, lately, and which I keep up to about 60° by the argentometer. I have got it too alkaline, and I wish to know what to use to acidify it with. As it is, it will not alter blue litmus paper. 2. I have been troubled by the paper not keeping well after being sensitised; it has not been fit to use the day after being floated, as it has gone so yellow when printing. 3. What effect would a few drops of ammonia have if dropped in the nitrate bath?"—In reply: 1. Add nitric acid till blue litmus paper is changed to red. 2. The acid will cause the paper to keep better. 3. Precipitate oxide of silver, and make the bath alkaline.

Blacking Dark Slides and Stops.—E. P. says: "I have some dark slides. The black of the metal plate is flaking off. Can you tell me what to coat it with to stop it, or reblack? How much bichloride of platinum to the ounce of water would be required to black a set of 7×5 rapid rectilinear lens stops? You gave a diluted solution. I do not want to buy a quantity if a few grains will be sufficient."—Clean off the old black from the slides, and reblack with dilute shellac varnish, to which some lamp-black is added. No actual proportions can be given, as the varnish varies in consistency. After the black is added, the varnish should be diluted with spirit until the coating dries dead. With too little spirit, the work will dry glossy; with too much, it will rub off. For the stops, the strength of the platinum solution is not very important. Twenty or thirty grains to the ounce of water will answer.

Salary.—Bob asks: "Will you kindly give me your advice on the following matter? I was apprenticed to a photographic enlarger for three years. The wage was 2*s.* 6*d.* per week for first year, 3*s.* 6*d.* for the second, and 5*s.* for third year. I have now only a week or two to wait, and I shall be out of my apprenticeship. I can enlarge well, copy well, and finish in black and white, although I do no finishing for the firm; I can also do trade printing. I have been asked to stay with the firm, but no scale of wages has been mentioned. Could you advise me what wage I ought to have? I may say that I am only seventeen years of age. Should feel obliged if you will assist me in this matter."—If our correspondent is proficient in all the things he mentions, he should command a salary of 1*l.* 5*s.* to 1*l.* 10*s.* a week; if highly proficient, more. Of course, salaries are always dependent upon the degree of proficiency, *i.e.*, the quality of the work produced.

Sensitising Paper.—W. W. Gregory says: "I should feel extremely obliged to you if you would give me the information I seek below. I am going in for home sensitising again, and it is such a long time since I did any sensitising that I forget how to keep up the normal strength of the silver bath. Can you give me a few particulars as to the use of the argentometer, and how should the strength be added? Is there not some multiplying business to do with it?"—The argentometer registers the strength of the bath in grains to the ounce of solution, and no after-calculations are required. As the bath gets weaker by use, so must its strength be made up by the addition of a strong solution of nitrate of silver. The argentometer only registers the specific gravity of the solution, whatever may be in it, therefore it is not an *absolute* register of the strength; but, in the case of the sensitising bath for paper, it is near enough for all practical purposes.

Copyright.—Birmingham writes: "Kindly inform me if I can copyright a photograph under the following conditions: A cycle agent asked me to photograph his stores. No terms whatever were come to. I did it, and submitted a proof. He approved of the photograph, but changed his mind about advertising with photographs, as he at first intended, whereupon I offered to take a bicycle if he gave a good order. He then ordered sufficient photographs for a large number of villages, and I had to pay him a balance only of a few pence for the bicycle. Finding the advertisement so successful, he has sent one of the photographs to have machine prints done from them, and, of course, don't want my hand-made prints. It seems to me scarcely straightforward, but I fear I am helpless to stop him. Your opinion will very much oblige."—You certainly cannot copyright the photograph. You were paid for taking it, if not in money, in money's worth. We scarcely see that you have anything to complain of in the transaction.

"*** Several answers to correspondents and other communications unavoidably held over.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1882. Vol. XLIII.—MAY 29, 1896.

Contents.

EX CATHEDRÂ.

Characterised by the unvarying care with which all the publications of Messrs. Kelly & Co. are produced, the eighth edition of the *Chemists' and Druggists' Directory* has just been issued. The first edition was published in the year 1870. The work includes the names of manufacturing chemists, wholesale druggists, drysalters, patent-medicine vendors, and other trades connected therewith, in England, Scotland, and Wales, and most of the principal towns in Ireland. It extends to over 800 pages, and its value to those for whose immediate information it has been compiled must be very great.

* * *

Photography is, of course, connected with the chemical and drug trades, and it may not be generally known that the *Directory* we have under review also includes a list of photographers, dealers, manufacturers, and others whose businesses may be said to be directly connected with photography. We turn over the pages of the book, and observe that the photographer and the photographic dealer are mentioned, whenever necessary, with the same minuteness and particularity as the chemist, the veterinary surgeon, the vermin-destroyer, the dentist, or the mineral-water maker. The book is sectioned off into a "List of Places," "London," "Country Trades," and "Ireland."

* * *

There appear to be, according to a hasty calculation we have made from the lists in the *Directory*, about 3000 professional photographers in England, Scotland, and Wales. In the principal towns of Ireland there are only about 100 photographers. London has about 400. We well remember some ten years ago going through an edition of this *Directory* published at about that time, and adding up the number of professional photographers as then given. Our impression is that the numbers we then obtained were nearly those that appear in the 1896 edition of this *Directory*. If this be the case, then professional photography has not expanded during the decade. On the other hand, the growth of photo-mechanical work has been very great; while the spread of the amateur—and may we add the pro-amateur?—has gone on unceasingly.

* * *

In our Correspondence columns we insert a letter from Mr. Holliday, Photographer, Alton, asking our assistance in tracing a man who appears, when sent out to do some photographic work, to have decamped with his employer's apparatus. We trust that the publicity we are giving to the matter may help our correspondent to recover his apparatus and bring the offending individual to justice. It is with regret we allude to the fact that this is the third case of its kind that has been brought under our notice in the course of the last few weeks.

* * *

Our suggestion that Norwich would form an excellent centre for next year's Convention, if the local photographers would form themselves into a small committee to undertake the necessary arrangements, has brought us a letter from Mr. R. W. Howes, photographer, of East Dereham, Norfolk, who gives it as his opinion that the local photographers would be willing to adopt our suggestion. We are much obliged to our correspondent, and trust that the Council of the Convention will take due note of the circumstance. In the meantime, possibly others of our readers have ideas on the subject of next year's meeting of the Convention which they might care to publish through our columns.

From some introductory remarks to Mr. Wilhelm Cronenberg's book, *Half-tone on the American Basis*, we learn that the following are the average wages earned by some of the workers employed in an engraving establishment in New York; exceptional salaries, of course, are not referred to. A capable half-tone photographer earns from 5*l.* to. 7*l.* a week; a line photographer 2*l.* 10*s.* to 3*l.* 10*s.*; a printer, well up in the albumen and enamel processes, 2*l.* 10*s.* to 3*l.* 10*s.*; an etcher in line and half-tone on zinc and copper, 3*l.* to 4*l.*

* * *

The price paid for blocks, Mr. Cronenberg informs us, has dropped in the last few years very much, and the golden time in this branch belongs to the past. The average price for blocks in line is about 3½*d.* to 5½*d.* per square inch; those for half-tone, irrespective of the metal employed, 1*s.*; and for vignettes the price is 1*s.* 3*d.* per square inch.

ORDINARY DRY PLATES FOR PHOTO-MECHANICAL WORK.—I.

Now that it has been recognised that at least as good results in photo-mechanical work are to be obtained upon dry plates as were formerly supposed to be only possible with wet plates, we may expect that before long a pretty extensive choice of such plates will be upon the market. Meanwhile it would be absurd to attempt to argue that the ordinary gelatino-bromide film as prepared for portraiture or landscape work is capable of competing in their own particular line with those plates specially prepared for the use of photo-mechanical or "process" workers; nor do we intend to argue that plates prepared or treated in the manner we are about to describe will rank in point of convenience side by side with the special article.

At the same time, where the latter, from any cause, does not happen to be available, a very good substitute may be found in the ordinary portrait or landscape plate, provided the operator is willing to go to a little extra trouble in adapting it to the new purpose. Thus circumstances may arise in which the habitual user of wet plates may be almost compelled to take advantage of the far greater rapidity of the dry plate, but may not have any of the specially prepared kind on hand, though the ordinary "rapid" plates may be in stock. In such cases, at the expense of a very little trouble, the ordinary plate may be pressed into service with little, if any, loss in the quality of result, and, further than this, old and deteriorated films, if free from mechanical fault or injury, may also be converted or restored to a practically useful condition.

It is not only possible, but, we think, very probable, that the long-standing prejudice that has rested against the use of gelatino-bromide plates has been based upon a huge fallacy. The superiority of the wet plate has been attributed to its greater capability of rendering, at one and the same time, density and clearness, while the dry plate has been condemned because, although any degree of density is attainable with it, it will not at the same time give the requisite clearness and freedom from veil or deposit in the clear lines. Perhaps, in times gone by, there may have been—and, undoubtedly, there was—foundation for this charge; but at the present day there are brands of dry plates on the market—not one only, but several—which, while they exhibit a sensitiveness that was undreamt of even ten years back, give greater brilliancy, clearness, and freedom from fog, when intelligently used, than the slowest plates of a decade ago. Why, then, are they not available for photo-mechanical work?

We have not the least hesitation in saying that it is mainly, if not solely, on account of their greater rapidity, and that, if by any means collodion or albumen films could be brought to the same high pitch of sensitiveness, they would be found to be every whit as unsuited to the purpose as gelatine. In saying this, we in no way wish to revive the old controversy of rapid *versus* slow plates for general work, *i.e.*, landscape or portrait; that has, we think, been settled by the production of rapid plates—far more rapid than any that were possible in the days when the controversy arose—that for ordinary purposes, and with the exercise of very little more care, will give results in every way equal to those obtained with plates of the slower kind, which were formerly supposed to allow so much more latitude. At the time when it was argued that slow plates were the best for landscape work, we took that side of the question, because at that time it was very rarely, and then only by accident, that the quickest plates prepared were free from serious defects or weaknesses that rendered their working far more difficult and interfered with the attainment of the highest quality of result.

Now that the most rapid plates can be obtained that are quite free from the old charge of lack of quality, we base their inferiority for process work on quite different causes, in which the plates themselves are not to blame, but the conditions of working; in fact, we take it, that the want of clearness and contrast is entirely due to their excessive sensitiveness, which renders it impossible to suppress the action of reflected light in the camera, whether from the sides of the camera itself or from the black or shadow portions of the subject to be copied. In the case of collodion or of the slower gelatine plates, the sensitiveness of the films for the weaker radiations is so greatly reduced that it is not difficult to secure the contrast required; but, with the quicker plates, it is impossible to give an exposure of any length that will satisfy the requirements of density in the lights that will not also suffice to seriously impress the portions that ought to be perfectly clear.

This fact—for fact it undoubtedly is—was forcibly impressed upon us, a short time back, when making some comparative experiments in the class of work of which we are now writing. With collodion plates, both wet and dry, we were able to obtain most satisfactory results, without any greater trouble than an extended exposure; but, with dry gelatine plates of the slowest ordinary kind, it was impossible to get anything but the feeblest and most unsatisfactory images. The plates used were a brand remarkable for the density, brilliance, and absolute cleanness of image for ordinary work, and their altered behaviour, under the new circumstances, suggested that the fault lay elsewhere. On examining the inside of the camera—which was an old-fashioned wooden-bodied one—from beneath the focussing cloth, with the ground glass removed, the cause was instantly suggested. With age, the blocking of the woodwork inside had entirely lost its "dead" character, and the light, passing through the lens from the margin of the picture we were copying, fell upon the semi-polished sides, and was reflected in such a manner as to light up the interior of the camera, and remove all wonder at our failure to obtain contrast with gelatine plates.

The Late Lord Leighton's House.—The attempt to raise the sum necessary to purchase the house, and retain it, in fact, of the late President of the Royal Academy at the price fixed by the relatives has, up to the present, ended in failure, consequently the house was submitted to auction one day last week. The biddings commenced at 7000*l.*, and proceeded feebly till 12,000*l.* was reached, at which point the property was withdrawn from sale. It is quite possible that now the original scheme might be carried out for a considerably less sum than that first asked by the relatives—35,000*l.*, we think. Such large amounts are not easily raised, even to secure a miniature palace of art.

Photographic Evidence Destroyed.—Reference has frequently been made as to the value photography would be as a witness in the case of riot and disorder if it were forthcoming. It is stated that, during the rioting amongst the fishermen at Newlyn on Monday last week, photographers, presumably tourists, were noticed taking snap-shots of the extraordinary scene. They were, however, compelled forthwith by the mob to give up the plates, as they might, when developed, serve as a means of identification of the ringleaders. Evidently the wily fishermen of Newlyn are fully alive to photography, and to what purposes it may be turned. They have, doubtless, been made more familiar with this matter by the number of photographic tourists who visit this picturesque fishing village, and include portraits of its inhabitants in their pictures. Be that as it may, they clearly will not have their illegal proceedings perpetuated by photography if they know it.

A Valuable Find.—A paragraph has appeared in some of the "dailies" to the effect that another genuine Raphael has been discovered, in a village bric-à-brac shop in Burgundy, by a connoisseur, who purchased it for five francs! It is a Madonna and Child, and is said to have at one time belonged to an historic collection. After the dirty, old canvas had been cleaned in Paris, it is stated that the purchaser was offered 300,000 francs for the picture, which offer he refused. About 4*s.* for a painting worth 12,000*l.* is not a bad investment, if the paragraph be true. It would be interesting to learn how a genuine Raphael got from an historic collection into a village curio shop, also how it was that the keeper of the shop was so utterly ignorant of its value. As a rule, this class of dealers, both on the Continent and here, generally know pretty nearly the worth of the things that come into their hands, or at least they do not under-value them when selling.

Photographic Poisons.—During last week inquests were held on two suicides who ended their existence by taking chemicals used in photography, yet neither of them was in any way connected with the practice of photography. One was a jeweller, who took cyanide of potassium. The other was a builder, who swallowed a solution of bichromate of potash. This is the first case, so far as we remember, of this salt being employed for suicidal purposes, although it is in such general use in the arts, and is retailed without any restriction as regards the Pharmacy Acts. We do not either remember a case of its being taken, internally, accidentally. This is a little surprising, seeing that the bichromate is in such common use, and that its solution so closely resembles in appearance many things that are taken as medicines or as beverages. As poisoning by this salt is so rare, very little seems to be known of its actual toxicological properties. Anyhow, it may be taken that it is not a deadly poison, neither is it very rapid in its action.

The Patent Office.—The annual report of the Comptroller General of Patents, Designs, and Trade Marks has just been issued as a parliamentary paper. From it there will be seen, as we mentioned at the beginning of the year, there was no increase in the number of applications in 1895 over that of the previous year, in fact there was a decrease of over 300. This is the first time since 1885 that there has not, each year, been an increase over the previous one. Of the 25,065 applications, 591 were, it is stated, made by women, a large proportion of which were, as might be surmised, in connexion with articles of dress. It would be interesting to know how many of the total number of applications were directly, or indirectly, in connexion with photography, and what is the trade, profession, or calling, of the applicants. As we have said before, comparatively few of the photographic patents are taken out by those connected with the business. Such callings as clerk in holy orders, engineer, surgeon, "gentleman," &c., figure conspicuously, the latter especially.

The number of applications for the registration of designs also shows a decline on the previous year. The applications for the registrations of trade marks, on the other hand, show an increase of over 250. But this branch of the business is of little interest to our readers. There was, however, a marked diminution of frequenters of the library—5089 less than in 1894. The year's receipts of the Patent Office were 187,012*l.*, which gave a surplus of 86,341*l.* With such an income, the building of the present Patent Office is little less than a national disgrace.

Reduced Railway Fares.—The principal railways have made a considerable concession in the matter of reduced fares to commercial travellers. From July 1 next they will be entitled to first, second, and third-class tickets to return to their homes from Friday to Monday at single fare for the double journey to all places over thirty miles distant. This privilege will be a great convenience to the travellers, and will, no doubt, be a source of additional profit to the companies. We believe it is the custom with "commercials," when they are "on the road," and more than thirty or more miles from home, to spend the Sunday at the hotel on account of the cost of railway travelling. With the concession it will often be more economical and far more agreable to them to spend the day at home with their families. This will mean a larger amount of business to the companies, which they would otherwise not get. There are some restrictions, however, accompanying the concession beyond the minimum distance of thirty miles. In order to prevent fraud, the traveller must be a member of the Commercial Travellers' Institution or kindred body, who will have to provide him with a ticket of membership as well as forms to be filled up when applying for the railway tickets. The Association card of membership must also bear upon it a photograph of the member.

We are afraid the privilege here granted cannot be taken as a precept for granting a similar one to photographers, which so many are just now so anxious for. The cases are widely different. The commercial traveller travels on business, and usually long journeys; the photographer for pleasure, and generally short trips. The former has succeeded in showing the companies that they would gain by an increased traffic which they at present lose. This, as we mentioned last week, is what photographers will have to do, we strongly suspect, before they will attain their end.

ON THINGS IN GENERAL.

The pages of this Journal have been largely utilised, and with great propriety, in bringing forward what has been termed "photographers' assistants' grievances," possibly the most marked example being that of a well-interviewed lady photographer, who gets as many pounds a dozen for her portraits as some photographers obtain shillings. It is open to speculation whether she is the employer responsible for the wild statements so freely made a few months ago, and repeated in most of the ladies' papers, that lady retouchers readily made ten pounds a week by the exercise of their skill. If what we read is trustworthy, it would have been more correct for her to have said shillings than pounds. It is too sadly true that she is not the only one of her kind, and, unfortunately, it is true that in a large number of studios the assistants' hours are both long and laborious, to an extent that prevails in scarcely any other business or profession. The suggestion that these unfortunate victims should join the Shop Assistants' Union is a good one, for there is little of either *camaraderie* or common ground of action among them at present. But our Editor sums up the position as accurately as suc-

cinctly when he says: "At the present time there is very little to learn in photography, as compared with the wet-collodion days, to qualify any one for an appointment in a third or fourth-rate studio, and that is the root of the evil. In any profession or calling where there is but little learning required the supply of labour is sure to be greater than the demand." Precisely. And the only persons who can reasonably expect to have a living wage and over are those who have attained a proficiency that will raise them head and shoulders above their brethren. Why should a man who, after a few months' practice, has picked up a knowledge of how to make a negative and produce a print, expect to obtain as much wage as a working joiner or a bricklayer who has served an apprenticeship, and needed years of practice to get proficient in a handicraft? It is hard to say this, but it is true. A poor sempstress, the living type of under-paid skilled labour, is far more entitled to a good wage. Years of practice were needed before she could earn her seven or eight shillings a week. But money has been made by photographers, and the ranks are rushed to by a lot of incompetent men who wish to do likewise, when a whitewash brush would be more suited to their abilities.

Another well-discussed topic has been the photographing of the national pictures. It seems a very simple matter. It is an undoubted fact that a "man with a camera" is often a nuisance, and certainly would it be the case if every amateur who applied might get a permit to photograph in the public galleries; especially would he be so looked upon if, as Mr. Lambert suggested, he took several days, so that he *might* get a good one eventually. The suggestion that the average amateur would be more likely, or as likely, to get good results as a professional accustomed to the work, is very unreasonable. There are very few photographers who know how to take a good negative from a bad (as regards condition) or even a good oil painting. There has, however, been one point raised that I entirely dissent from, the danger to be anticipated from the handling, and glazing, and unglazing the paintings. Any photographer who knows his business can take just as good a negative from a glazed as an unglazed picture, so long as the interior surface of the glass is clean, and provided, of course, that he is possessed of the necessary appliances.

What an interesting revival of old memories was brought about by Mr. Atkins's paper on *Micro-photographic Reductions* at the London and Provincial Photographic Association the other day. It is nearly half a century since these curiosities were first introduced, I believe, by the late Mr. Dancer, the well-known Manchester optician, who, I think, first used the name micro-photographs. There was rather a craze at the time for making them, and somewhere among my optical lumber there is stored one of the pieces of apparatus sold at the time for the purpose of making the little slides (Mr. Dancer must have sold thousands of the Lord's Prayer, the Creed, &c.). It is somewhat after Mr. Atkins's instrument, with micrometer screw to make accurate adjustments for the difference between visual and actinic foci; but it had a little dark slide, and the "uncapping" was done in the slide itself by turning a little swivel door. The Hon. Secretary was correct in his account of how these things are done commercially by a battery of lenses. Most of the single-subject pictures, mounted on the end of a Stanhope lens, and found in commerce, were done by Dagron, who used a battery of lenses. I am able to supply further details, not generally known, of how these little things are done. The small photographs were done on one sheet of glass, cut up into small squares, and then cemented with Canada balsam to the end of the lenses. Then, when set and hard, the whole piece, lens and photograph, were turned in a lathe and made into a smooth cylinder, a method which, it will be seen, readily accounts for what is often a puzzle, the accurate fitting of photograph and lens.

Speaking of caramel at the North Middlesex meeting, a description was given of the way to make it. I think by far the best way is the plan adopted by the cook. The sugar is melted as described, but the frothing stage is allowed to be passed, and the material then becomes liquid. At this point water is deftly poured in gradually, and with much stirring. If properly done—and experience is needed—a beautiful thick syrup is obtained; if wrongly done, the result is—mess and early English.

FREE LANCE.

PHOTOGRAPHIC SOCIETIES AND PHOTOGRAPHIC ART.

[Photographic Club.]

IN what way can a Photographic Society or Club do anything for Photographic picture-making?

The answer to such a question would doubtless be, as far as some people are concerned, "by the reading and discussion of papers upon art matters." Before accepting such a reply it is necessary to consider what such papers are, and whether their publication and the discussion which sometimes follows is likely to be of any use.

The literature of the subject is very great. More than a dozen treatises have been written on it, many columns of the photographic press have been and still are devoted to it; in fact, I have seen periodicals which contained little else except the advertisements. The subject has also received attention in the circulars distributed to their customers by some west-end and provincial photographers, in forewords, or what English writers would describe as prefaces, to the catalogues of exhibitions, in an epitaph, and in other quarters too numerous to mention. Reputations of a kind in various little photographic coteries have been made by men who never exhibited a photograph, on the strength of the opinions, or what they believe to be such, embodied in their writings on photography and art. In fact, the little brook, to which the first paper read before the Royal Photographic Society might be compared, has expanded into a broad river, which, from its volume and from the mud it carries, can only be compared to the mighty Mississippi itself.

Much of this literature I have read, and, if you will bear with me a few minutes, I will give you a brief analysis of the compound, for such it is. Chemists who wish to analyse a substance the composition of which is unknown would tell you that they endeavour first to isolate it; and, applying this principle to the literature of photographic art, we must proceed to get rid of the quantity of unnecessary verbiage in which it is dissolved. Much of this art writing we find with the information or instruction, when any is present, dissolved in an ocean of words, drowned in a sea of gush. We find it accompanied with rhapsodies upon the beauty of sunlight, of mist, and so on, which are too well known to need further description. Eliminating all this foreign matter by a process akin to evaporation, we can, if we care to go on long enough and to deal with a sufficiently large quantity of solution, isolate sufficient of what may fairly be described as literature dealing with photographic art to enable us to make out its composition.

THE LITERATURE OF PHOTOGRAPHIC ART.

It will usually be found to be a compound, or rather a mechanical mixture, of some of the following:—

1. *Capital letters.*—These are very prominent and not entirely useless. It is the easiest thing in the world to pick out the "Art" papers in a photographic journal by merely turning over the leaves and observing how often capitals occur. Much time may be saved by noting this, which is what a chemist would call a characteristic reaction.

2. The next most common constituent is *praise of the writer's fellow-workers.* This is the most creditable feature of the whole thing. We have not very many constant writers on photographic art in London, but the regularity with which they praise one another, and the unstinted admiration which each obviously possesses for the other photographers in his particular clique, must strike every reader, and speaks volumes for their freedom from the jealousies to which artists are said to be particularly prone. It has been suggested by irresponsible and anonymous scribblers that this flattery is systematic, and is practically the condition for admission to the circle, but I am quite confident that there exists, in writing at least, no agreement for the interchange of fulsome adulation, such as is hinted at.

3. *Assertions that photography is art, and that everything which does not relate to art has no serious import to a photographer.*—This is usually coupled with suggestions that those who pay any regard to the scientific or technical aspects of photography can never hope to achieve any success in artistic photography. (I would here remark, in parenthesis, that the converse of this proposition, *i.e.*, that those who give any attention to artistic photography can never hope to achieve success in photographic science or technics, has never been put forward by these writers, although I should imagine it is quite as reasonable.) Under this heading would be grouped fifty or sixty controversies which have taken place at different times, which may be summarised in the following manner, eliminating first the unnecessary verbiage.

A. "Photography can never hope to be regarded as one of the fine arts."

B. "A. is a perfect fool, and knows nothing of photography."

A. "B. is a ditto, and is absolutely devoid of art knowledge."

B. "You're a liar!"

A. "Ditto!" and so on, until the editors stop it, or the gentlemen get exhausted.

4. Our fourth constituent is more technical. It consists of *statements as to the amount of focussing necessary*, and of asseverations that photographs focussed sharply, or printed on glossy-surfaced papers, or toned to a warm colour, or mounted on a white card, or having the clouds printed in, or depicting scenes in nature which are themselves "pretty," or worse, are absolutely unable to be regarded for a moment as betraying any artistic perception in their producer, or *vice versâ*, according to the views of the particular writer. Under this heading would come, of course, all writings intended to convince that all photographs should be able to able to bear examination with a magnifier, that rough printing papers are a ridiculous fad, and that painters who depict forms in other ways than a lens would do are wrong and their pictures false. The mark of this branch of the subject is its dogmatic nature, the proofs offered of each dogma taking the form of repeated assertions.

The foregoing constitute by far the greater proportion of the literature of photographic art; but this is not all. Reading carefully and continuously, one does now and again come across passages containing hints for the guidance of the serious worker, and suggestions as to what to do, and what to leave undone, to obtain the most pleasing pictures. This would seem to point to the conclusion that some of the papers might, under certain circumstances, be of use, but it is only a momentary illusion. A little care will show that every point so brought forward is to be found elsewhere. I do not deny that I have heard some of this writing described as very readable; it may be to some people, but is it in any way instructive? Of course there are some papers which both instruct and please. Dr. Emerson has written a book on the subject which would certainly come under this category, but then it deals with much besides mere photography, and has a lot of interesting information about Egypt, Dr. Emerson himself, the platinotype process, and so on

Mr. Robinson and the Royal Photographic Society.

Mr. H. P. Robinson, who has written much upon this subject, in a very recent article has repeated the charge that the Photographic Society has ceased to foster photographic art, and brings forward the statement of an Hon. Secretary of many years ago that, "although the meetings of the Society should be devoted to the scientific rather than the artistic side of our subject, an occasional paper on practical picture-making would be welcome," as a proof of his accusation. I am not here to-night to defend the Photographic Society of to-day, much less the Photographic Society of eight or ten years ago, when Mr. H. P. Robinson was one of its shining lights, or I should point out that the casual observation of one of its officers, on his own authority—an observation which the Council, on the part of the Society, distinctly repudiated, as Mr. Robinson has, I believe, admitted they did on his own initiative—cannot be taken as in any way binding the Society. But all this is beside the mark. I am simply here to give you my own opinions, as a member of the Photographic Club, on the way in which photographic clubs and societies can or cannot foster photographic art, and in that capacity I must say that the statement of the particular Hon. Secretary quoted is not an altogether unreasonable one.

In 1868 a very interesting and useful book, entitled *Pictorial Effect in Photography*, was published, which, to use the author's own modest expression, "has managed to survive." Whether the ideas put forward in that work were new or not is immaterial, but, at any rate, it has been a little gold mine to those of the subsequent writers on the subject who have recognised the importance of including at least something or other of use to the student. It is little or no exaggeration to say that, in ninety-nine hundredths of the papers which have been read, and articles which have been written, since, there will be found nothing of service which is strictly germane to the subject which is not to be found, expressed more happily in *Pictorial Effect*, or, to go still further back, in *Burnet*. What possible benefit to photographic art could accrue from the reading of a rehash of Mr. Robinson's valuable work, diluted more or less, as I have indicated, at every other meeting of every society, let us say? It is difficult to imagine. It might even have injured the sale of the book.

I would go further than this, and say, that not only does the emission of this kind of literature weary the reader, without assisting him, but I am convinced that it has a very serious moral or intellectual effect upon its writers. I will not stay now to give you many examples of my meaning; one must suffice, and I select it, not as the worst, but as coming from one who, by occupying the highest place, has most room for deterioration.

"At the end of 1894 the Photographic Society of Great Britain was wound up, and another Society founded on its ashes, which is almost entirely devoted to the science, mechanics, and trade of photography." That sentence is a quotation from one of the latest writings of a well-known photographer. I will not do more than point out the skill with which a legal formality has been described so as to deceive those unacquainted with the actual facts to believe that something quite different took place. To my mind, the penning of such a paragraph is not so much a matter for criticism as for regret—regret that one, whose work all photographers must admire, should injure himself by attaching his name to such a statement. It would be only charitable to conclude, if it were not so improbable, that for once the facile pen has failed utterly to convey the author's meaning. Whatever may be the reason for such an utterance, I can only regard it as one example of the effects which much writing on photographic art has on the performers.

Now, the question I ask is, What useful purpose could be served by the iteration and reiteration of this "art" writing? Does it lead to the acknowledgment by painters that photography is a fine art? and, if it did, what is the use of the expression of opinions formed simply by repetition, as one teaches a parrot to talk? If you ask for my own opinion, I would give it as this: That the emission of a hundred thousand pages of such matter is less convincing, using the word as referring to a reasoning process rather than a parrot lesson, than the production of a single photographic *picture*.

How can a Society Foster Photographic Art?

Neither writers, then, nor readers, are benefited by it, and we come back to our original question, How can a club or society foster photographic art? Clearly, it must be in some other way than by the reading and discussion of papers. The fact is, "Art is a matter which cannot be *profitably* discussed, talked, or written about;" a great artist has said, "It must be felt." The only *clear, definite, and constant* way in which help can be given is by affording every opportunity for the exhibition of photographs. A club may, from time to time, as occasion shall arise, help in other ways, but its duty at all times is clear in this one direction.

It can further this object by holding or assisting to hold exhibitions of the works of particular photographers, living and dead, such as have from time to time been held by the Camera Club and other institution and by the holding of periodical exhibitions in which the latest productions are on view. For this reason, then, I should like to see the system of "one-man shows" increased and extended, so as to give every photographer an opportunity of seeing what has been done by those who have gone before him; so that every worker may know where his starting-point will have to be if his work is to constitute an advance. To do this, a society meeting in London is not sufficient, but all over the country the local societies must endeavour in the same way to show their members the present position of the high-water mark, as it were, and to educate them in the one method by which it can most directly and efficiently be done. This should be particularly the case with the works of deceased photographers. I would suggest that each photographic society which has at heart the interests of photographic picture-making should form, or at least endeavour to form, a collection of the works of the mighty men of the past; such a collection will not only show what has been already achieved, but, by indicating how much we have already progressed, will help to excite in the more serious workers a conviction that much may still be done.

About Exhibitions.

As regards the open exhibitions, where the most recent work can be seen, there is much to be said. The actual rules and regulations seem to occupy much too great a space in some people's minds. As a matter of fact, all exhibition rules and regulations, other than those which refer to the matter of making the exhibition pay its way, should be framed with two main objects in view. These may be summarised by saying that, as far as possible, the exhibition should contain the best work of *every* school, and *that*, once got together, it should be displayed so that those who are likely to profit by it can see it under the most favourable circumstances. To carry out the first of these conditions, it is, above all things, necessary to convince the exhibitors that the works to which they have given their thought and care will be considered and judged, not by any particular or select few of their rival exhibitors, who will now and then admit a picture or two by some one outside their own circle, to show their impartiality, but by a body of men in whose election, if they will, they may have a voice, whose names are known and whose merits are discussed months beforehand. The minor details of such an exhibition—whether medals shall be given or not, what charges, if any, shall be made to exhibitors, whether the show itself shall be held in the same gallery as a case or so of cameras and lenses (an unpardonable offence in some eyes)—must be largely passed over here; but one point I will touch upon: It is sometimes said that an exhibition of photographic pictures should not be held in connexion with one of apparatus and other technical exhibits; this is, in my opinion, a very great mistake. The whole

aim of an exhibition is to get together the best selection of things to be seen, and then to show them to as many as possible of those interested. Many a photographer who is interested in picture-making will go to see an exhibition where he can see everything photographic that is new and attractive to him who would not feel inclined to devote a day and to take a long journey to see a collection of the works of some forty or fifty persons in one particular direction and little more. For this reason, I would say, Make your exhibitions as widely interesting as you can, provided a comfortable view of none of the various exhibits is interfered with. There can be no doubt that an exhibition representative of every phase of photography, and not of one narrow school of one particular branch of it, an exhibition commanding the confidence of the exhibitors in the Judges as quite disinterested and impartial, and one visited by thousands of photographers, is infinitely more powerful in encouraging photographic art than one which is the reverse of all these. We hear nowadays strange things about exhibitions and exhibition management. One London show is said to have done much for photographic art, as far as I can make out from the claims of its supporters, because it has succeeded in disposing of a number of photographs, more or less permanent, at prices which suggest a fancy fair. I see little to cavil at in selling photographs for what they will fetch. Many of the pictures at Pall Mall every year are disposed of to visitors, especially since the 1893 Exhibition, when means were taken to bring the fact that many of the exhibits could be purchased before the notice of the public, a hint of which the Photographic Salon availed themselves when they opened shortly afterwards. In fact, the highest price I ever heard of being given for an exhibit was paid for one at the Pall Mall 1893 or 1892 Exhibition, I forget which. It is important to remember, however, that, while this sale of pictures is, no doubt, advantageous both to the coffers of the exhibitions and to the professionals who exhibit, it has little or nothing to do with photographic art, but is more properly considered under the heading "Photography as a Business."

Under the same heading would be included an exhibition organized to advertise its promoters and exhibitors in the lay press, and to induce the outside public, if it troubles itself about such things at all, to regard these individuals as the only personages in the photographic world. A distinguished member of the "Linked Ring" once remarked to me that no small amount of the success which is supposed by some to have attended that mysterious body was owing to the skill with which the non-technical journals had been *manipulated*. I did not gather from that that anything in the nature of bribery had been or would be employed, but that advantage had been taken of friendship and acquaintances to get particular workers' photographs eulogised to an extent which would not have been done spontaneously, or by any one acquainted with photography. It did not seem to have occurred to my informant to look at the moral aspect of the question, it seemed to be regarded as perfectly blameless, and I have heard it suggested that the Royal Photographic Society should make use of its influence in a similar manner. May I venture to express the hope that neither that body nor any other photographic society will ever resort to such questionable means to attract exhibitors?

Photographers as well as Artists should be catered for.

The people for whom exhibitions are primarily intended should always be borne in mind. At Pall Mall most of the leading artists are to be seen every autumn (taking advantage of the hints for picture-making, no doubt), and I have read somewhere that a number of artists visited one of the Salon Exhibitions. I gather, however, from the fact that this was specially recorded, they do not make a practice of going to the Dudley Gallery. But why should they go there or to Pall Mall either? Let them by all means pay their shillings to such good causes, but let us not forget that it is the photographers who should be catered for first and foremost if our aim is to further photographic art. By all means get the artists and the general public to go and to buy the pictures, it is useful financially; but this should not be the aim and purpose of a photographic exhibition, nor should it be put forward as a proof of its success.

By holding exhibitions, then, on the lines I have suggested, a society can do much to foster and advance the art side of our subject. What can be done further with this aim must depend upon the times and upon other circumstances. One opinion has long forced itself upon me, and that is, that these papers upon "art," as they are called, may encourage smart writing, undoubtedly foster toadying, jealousy, and ill feelings, but without apparently bringing any commensurate benefits whatever.

One word more and I have done. From the nature of my subject, I have dealt entirely to-night with photography as an art. I hope no one will go away with the idea that I am one of those who regard this art spect of photography as the be-all and end-all of photography as photography. There are some, I believe, who hold that it is no part of a photographer's business to endeavour to perfect our processes, or to increase his individual skill in using them; that, in fact, the sole aim of a photographer should be to "paint by light," using the word "paint" in its narrowest sense, as implying the object "pictures." This is, of course, the opinion of the enthusiast, and will be echoed and re-echoed by those who are not likely to achieve success in any other direction. I know a gentleman who, I have no doubt, would maintain that the whole aim of a photographer should be to take pictures by magnesium light. Let us clear away from our minds any such narrowing prejudices. Photography is surely something wider than this. It is true that this is the particular direction in which public interest is most manifested, and that ten people will rush to see a pretty picture for every one that goes out of his way to see an example of some other form of applied photography. This is in itself an argument against the devotion of too much collective effort to encourage picture-making. The tendency nowadays often is to lose sight of the fact, none the less true in consequence, that this particular section of photographic work is but one of the many divisions of applied photography, and that it has no more claim to be the alpha and omega of the photographer than has photo-micrography, astronomical photography, or the manufacture of transparencies for the kinetic lantern. Is not this very tendency a reason for the concentration of the more powerful efforts of the societies on those branches of the craft which are suffering most from neglect, and a reason against spending too much valuable effort in fostering that which, from its very nature, is of all the sections of our subject that best able to stand alone?

R. Child Bayley.

PHOTOGRAPHIC WORKERS AT WORK.

V.—Messrs. Illingworth & Co. at Willesden Junction.

Our visits hitherto have been to works at which photographic materials of one kind or another have been made; on this occasion, however, we saw the production of photographs themselves, rather than of implements by which photographs are produced. Messrs. Illingworth & Co. have recently opened an attractive showroom at No. 5, Soho-street, where specimens of the firm's work in the shape of prints in carbon, platinum, and silver, and enlargements of all kinds are to be seen; and, after a call here, we took advantage of the excellent train service from Euston to inspect the works at which they are produced. Nominally, these are situated at Willesden Junction; actually they are at Harlesden, which is the less known, but more strictly accurate, title of the rapidly growing district in which that far-famed railway centre is located.

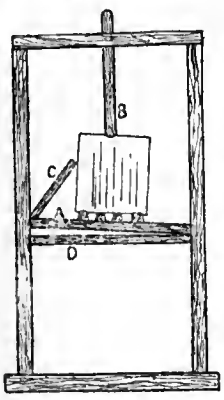
A few minutes' walk from the station brought us to the works; these are in two parts: the first an ordinary, double-fronted house, which has been adapted to the business to be carried on in it; the second, and newer, portion consisting of a series of buildings, in which the bulk of the photographic work is now done, the house having been soon outgrown.

The first department to be visited was devoted to carbon printing, and occupied a long one-storied building, divided into two parts, of which one was glazed with yellow fabric to serve as a filling room for the frames, and the other, by far the larger, portion was used for developing and finishing. In the first was to be seen a plentiful allowance of table space, such as its purpose required, together with arrangements for spotting the negatives, and carrying out those little operations of a similar nature which are needed, more or less, by every negative, in order to secure the best result possible from it. The developing room is of oblong shape; down one side of it are the squeegeeing slabs for mounting the tissue, down the other are the developing tanks. Slate slabs are employed here for squeegeeing, each slab being mounted in a wooden sink to carry off drippings. The tanks on the other side of the room are four in number, and are made of ample proportions of galvanised iron. The first is used for mounting the tissue, and is, of course, full of cold water, the second for developing, containing hot water. We noticed in this an ingenious arrangement for syphoning off the dirty water, so as to keep the tank nearly full of water, which was nothing like so dirty as is usual in carbon works, the supply coming from a boiler heated by gas, and capable of delivering twenty gallons, boiling, in twenty minutes. The other tanks contained alum and cold water respectively, and call for little notice.

In front of this building is a large yard, which, enjoying a north aspect, and sheltered from the sun by the main body of the works, is eminently suitable for the operation of printing, which is there carried out in fine weather.

Parallel with the building in which the carbon work is carried on is a large two-storied erection, the upper floor of which affords accommodation for enlarged negative-making. In a spacious dark room here, the atmo-

sphere of which was strongly flavoured with ether from the collodion, we found Mr. Samuel, a wet-plate worker of many years' standing, engaged in making enlarged negatives. The dark room was roomy, the walls covered with black waterproof paper for easy cleaning, while openings on one side of the room, each with a camera fixed in front of it, were provided for enlarging purposes. In front of these cameras ran lines of rail carrying the easels. In this case the latter, being constructed for wet plates, were mere frames, in which the plate is held as shown in our sketch. The bar, A, carries a series of wooden blocks, notched at the top, into which the plate is dropped, and B, which is similarly notched underneath, is brought down to hold the plate vertical. The latter bar, B, is made to move stiffly through the opening provided for it by means of a spring, and so no further clamp is requisite. The bottom bar, D, can with A be shifted up and down the framework to the required height, and then clamped. In case the image is not square on the negative, this bar can also have one of its ends tilted as shown, so as to incline the plate to one side or the other, and so to correct the enlarged image. No dark slide is used in this apparatus, the focussing screen being inserted into the notches in the easel, and the image centered and focussed. The arm, C, is then brought down till it touches the screen, and acts as a guide for the position of the sensitive plate, and, the lens being capped with yellow glass, the plate is substituted for the focussing screen and the exposure made.



The plates to be coated with collodion are supported either with a pneumatic holder in the case of small plates, or with large ones on a ball, and the silver bath is a horizontal one, mounted on trunnions, and containing a box for the solution at one end, so that the bath can be tipped up to remove the plate. Hypo is employed exclusively for fixing.

The wet-plate dark room occupies a considerable portion of the upper part of this building, but there is still a large room freely glazed in which enlarged negatives are made in the camera from prints, &c. An arrangement in use here struck us as being very convenient, and we give a description of it for the benefit of our readers. Every one who has done any enlarging in the camera must have experienced the inconvenience of adjusting the position of the print on the easel to that of the camera, especially when they are some little distance apart. It necessitates a considerable amount of oscillation between the easel, to adjust the picture, and the focussing screen of the camera, to see whether the adjustment has been made correctly. At Willesden, a little invention of Mr. Illingworth's obviates this altogether. The camera slides to and from the easel in guides, and can be fixed at any required distance, and between the guides and just underneath the camera are four cords. The board of the easel to carry the print or what not to be copied slides freely in two series of grooves, one vertical and the other horizontal, much in the same way as the front of the camera with rising and horizontal movements. Two of the cords pull the movable portion of the easel to the right or left, the other two pull it up or down, and its exact position can be settled in this way, while the head is under the focussing cloth and the camera at any distance from the easel. It struck us as both simple and efficient.

We now went into the ground floor of the same building. This is occupied with bromide enlarging, in which the firm do a considerable business. The arrangements for illuminating the negatives are similar to those in the wet-plate dark room, openings in the wall admitting light from a series of fluted glass mirrors. The floor here is of concrete, and the rails carrying the easels are bedded in it so as to prevent the slightest danger from vibration. The chief operator here, observed, in showing us the various operations, that the exposure required by the bromide paper was never measured with a watch, and that they but rarely went astray. This, of course, led to an inquiry as to how it was done. "I hold my finger between the lens and paper, so—" says our informant. "so that its shadow falls across the most opaque part of the negative, and, by noting the difference in the illumination of the least lit part of the enlarged image and that where no light falls upon the paper at all (the shadow of my hand), the exposure is easily estimated with a little practice." This was certainly the case in the particular instance which we saw, the print developing up brilliant, but not too hard.

Ferrous oxalate is here used exclusively for bromide paper work, with excellent results. The oxalate and iron solutions are kept in large jars fitted with a tap, from which the necessary quantities are drawn off and mixed. Glass-bottom dishes are employed, and the point at which to stop development is decided by looking through the enlargement, on the bottom of the dish, at the yellow lamp. The glass baths not only permit this examination to be done easily, but are also very economical of developer, three ounces being sufficient for a print up to 15 × 12. Acetic acid is employed to get rid of the iron, and is used both before and after fixing. The enlargements when fixed are taken out of the dark room to be washed, an operation carried on in a series of large tanks.

The washing of a silver print or bromide enlargement is an important matter, and is evidently so regarded by Messrs. Illingworth. No mechanical washers are employed, but the prints are transferred from tank to tank, and are laid down on an inclined slate slab between each such transfer, sprayed on with a hose and squeegeed. "This," says Mr. Illingworth, "is the old-fashioned way of thirty years ago, with silver prints, and, although more trouble and labour than any mechanical washing, is in my opinion more efficient." This would certainly seem to be the case, and there could have been very little trace of hypo in the prints which we saw undergoing this very thorough form of washing.

So far we have been in the new buildings specially erected for the work done in them, but we now leave these and pass into the house in which the works started. Here we find the offices, together with two rooms in which a number of artists are to be seen colouring and working up enlargements. At the back of these premises are the rooms in which platinotype and silver printing are carried on, and in which the various prints, &c., are mounted. Here also is a packing room. These operations call for little remark from us, no departure from recognised methods being noticed. Before leaving, Mr. Illingworth pointed out to us some vacant land beyond the works as giving him the opportunity to enlarge if necessary, a proceeding which, to judge from the busy condition of the firm, is far from being unlikely; and expressing our hope that this will soon be the case, and thanking him for the trouble taken to enable us to lay this article before our readers, we return to Willesden Junction, wondering whether photography as a business is in quite such a bad way as some of our pessimist friends appear to believe.

PHOTO-MECHANICAL NOTES.

THE possibility of taking direct half-tones from nature, at which I hinted in my last notes, and referred to in a recent editorial in this JOURNAL, has been long ago proved. The earliest attempt within my experience was made by the late Mr. R. L. Kidd, who, acting upon my suggestion, had a portrait of himself taken through a Levy screen. This was in the early part of 1894. It was on a dry plate, and was very successful, but I forget the exposure. One thing the negative was chiefly notable for, viz., the most subtle rendering of delicate tones in the high lights. For instance, a strong high light like a white collar was rendered with beautifully soft shade in the curves and folds, and the flesh tints were also modelled and rounded in such a way that the negative seemed to have had all inequalities smoothed down by a skilful retoucher. Whether Mr. Kidd followed up this experiment I don't know, probably the matter was put aside for further investigation in those spare moments which the busy man fondly anticipates but never attains; and his lamentably sudden death, which occurred not many months after, put an end to it for ever.

Another experiment of the kind which I well remember, and in fact I have the negatives somewhere, was an attempt of mine to take a landscape through the screen, whilst on a visit to my friend, Mr. W. A. Whiston, at Llandudno. This was in the summer of 1894. The view was from the window of that gentleman's house, and he will be able to corroborate me as to the circumstances. To the best of my recollection, the exposure was two minutes, with a square stop corresponding to *f*-16. The plate used was a now defunct Photo-mechanical, and the camera an ordinary half-plate, with Dallmeyer R.R. lens. The dark slide was, of course, made sufficiently large to take the screen—133 line Levy—with a separation of one-sixteenth of an inch from the plate. It required three shots to hit the exposure which would give dots in the shadows. The negative was printed and etched, and there was a quality of vigour and softness, quite absent from the usual reproduction from a silver print.

It may, no doubt, seem strange that I did not follow up these promising results, but the fact is I did not think more of them than that they were successful "flukes," and the half-tone process had

been so little investigated at that time that I could see no sure basis of working; and it was not to be expected that one could go into the field to take half-tone negatives by a process "of trial and error." To do that, one would have to take out a dark room on wheels like the old wet-plate perambulator, and that was impedimenta not to be lightly considered. Any way I have had no time to do anything more in direct half-tone since then.

No doubt, direct half-tones had been taken before my experiences, but I have not heard of any instances. However, our American friends have, I believe, been cultivating this branch of late, and it is a regular thing to send to the process man the actual objects for catalogue illustrations in half-tone. The firm of Blanchard & Watts, Boston, U.S.A., have been conspicuously successful in the direct reproduction of articles of jewellery, silver plate, &c., and a wonderful amount of detail is secured. There are no heavy shadows, the common drawback to direct photographs prepared for the wood-engraver, for the skilled half-tone worker knows how to break up the shadows with minute dots in the negative. Another notable direct half-tone was published not so long ago in the *Engraver and Printer*. It was a street view, the negative and block having been made by the Suffolk Engraving Company of Boston.

There is, in fact, no difficulty in making direct half-tones from still objects, and especially in a well-lighted studio, or out of doors in close proximity to the dark room. In such case, the exposure, which is the crucial part of the whole matter, can be tested. Whether the making of half-tone negatives from nature, anywhere and everywhere, can ever be done as readily as ordinary negatives are now made, is another question. So much, however, has been done of late to systematise the half-tone process, that I do not think it will be long before we hear of some one regularly taking direct half-tones.

Some difficulties of apparatus will have to be surmounted first, but no difficulty can long withstand the ingenuity of modern camera-builders. It will, for instance, be necessary to have a screen with much thinner cover glass than at present, so that as large an aperture as possible can be worked within the lens. The screen adjustment must be in the camera, not in the dark slide, so that several double backs can be used, as in ordinary landscape cameras. The diaphragm system must be so calculated as to work in geometrical proportion to the screen and focal extension without having to resort to guesswork. Further, it will be necessary to adopt some plan of apportioning the exposure of foreground and sky in landscape work. The lens will, of course, be fitted with a prism for securing reversed negatives. The exposure will have to be accurately timed by one of the numerous meters on the market, or in some definite manner, though it may be mentioned that the slow "process" plates which would be used give a great amount of latitude, and a little over-exposure can easily be corrected by means of a reducing solution. The dodge of flashing white cardboard in front of the lens may be resorted to in order to quicken the general exposure.

Now, if such a process as I have indicated comes within the range of practicability, what possibilities it opens up for illustrated journalism. The negative of some important scene could be printed on a copper or zinc plate, and etched out within one to one and a half hour from the time of its being dried off, and the reproduction would have lost none of the vigour of direct photographing. It may be urged that the use of slow plates and the retarding action of the screen would limit the class of subjects that may be taken in this way; but, as rapid plates are now made with wonderful freedom from fogging, it would be quite possible to select a suitable brand, and by careful adjustment of screen distance and diaphragm no serious loss of sharpness would result. The whole tendency of recent investigation and practice has been to show that the reason dry plates have not rendered such good results in the past has been that process operators did not work the optical conditions sufficiently exact for them, and a looseness of working, which was permissible with the wet-plate process by reason of the ease with which the result could be modified by intensification and reduction, was soon found to be impossible with dry plates.

I dare say it will be amateurs who will lead in any advance in this direction. Professional workers have no time for experimenting. But amateurs have not yet grasped the half-tone process, so it may be some years yet before direct half-tones are a regular thing. I hope, however, that those who have leisure, whether amateur or professional, will give some attention to this matter, which appears to me to open up a very profitable field. WILLIAM GAMBLE.

RENARD'S PROCESS AND APPARATUS FOR FLATTENING MOUNTED PHOTOGRAPHS.

M. E. RENARD, the patentee of this device, says in reference thereto:—

"When a photograph is mounted on card, its shrinkage causes the card to present a concave curvature on the face, sometimes in the length, sometimes in the breadth, sometimes in both.

"My invention relates to means of removing this curvature so as to render the face of the photograph flat.

"For this purpose I provide boards, convex, some longitudinally, some transversely, and some both ways; and on one of these, of suitable form, I place a mounted photograph, or a number of these, their convexity facing the convexity of the board. I clamp the whole within a rectangular frame, which is made of wood, with a metal rim fixed on its upper face, this rim projecting inwards all round.

"The mounted photographs, being thus clamped between the convex board under them and the flat rim above their margins, are flattened, and, while thus clamped, are kept a few minutes in a hot chamber, whereby the flattening is rendered permanent."

RECOMMENDING A HAND CAMERA.

I AM often asked to recommend a hand camera. "Tell me which of all the various hand cameras I see advertised should I buy," writes one seeker; and "How am I to select the best hand camera in the market?" plaintively asks another. To tell the truth, I would as soon recommend a saddle back to a friend (says the Editor of the *Journal of the Photographic Society of India*). We all know that in the abstract the horse is an animal that can be ridden, just as we know that a hand camera is a piece of apparatus in which a photograph can be taken; but, whether the hack or camera I would recommend is the best for the purchaser's purpose depends on so many circumstances that I prefer to be excused. For instance, for the beginner in photography a hand camera is not to be recommended at all. His experience should be gained with a tripod camera, a rapid rectilinear lens, and a slow plate. When he has mastered the rudiments of exposure and development, spoilt a few dozen plates, and given vent to his feelings generally, he is in a more humble condition, and so better qualified to attempt work on a hand camera. Even at this stage of the photographer's progress, I doubt the advisability of trusting him with anything lighter or handier than a half-plate tripod camera. I doubt, indeed, whether one's progress is ever so rapid as to warrant the total abandonment of our old and trusty friend, the tripod.

In some of the recent home journals may be seen a portrait of the late Mr. J. Traill Taylor, the accomplished Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY. He is depicted with a half-plate camera fixed to its tripod, like a trusty rifle—"at the shoulder." Here was a man who knew more about photography than most people, and his attitude and his camera alike are silent witnesses of what he thought was a good photographic apparatus. Personally I have never found anything in the shape of a hand camera to beat this good old-fashioned instrument when serious work is in hand. But the average amateur is not a serious worker. On the contrary, his whole and sole aim is the acquisition of numberless little pictures of scenes he has visited, episodes he has passed through, and people whom he has met. He argues that he cannot pass through life with a tripod camera at the shoulder, and could never get the pictures he wants if he had to "ground arms" and pass through the elaborate drill involved in focussing, plate-loading, capping, presenting, and firing a tripod camera. And he is quite right. For such work nothing but an ever-ready hand camera, a snap-shotter, so to say, can yield him the "bits" he yearns after.

Now we are approaching our subject. Amongst the essentials of a serious half-plate tripod camera are a firm support, a good lens, a glass plate-holder, arrangements for focussing, and a cap. There may be added to these many elaborations, such as rising and falling fronts, swing backs, lens shutters, &c., but they all tend in one direction, namely, to the seriousness of the work. In the earlier days of the hand camera these essentials were all more or less kept in view, and to this day certain makers of them—themselves serious probably—insist on the necessity of double backs, focussing arrangements, rising and falling fronts, and swing backs. When very positive, as well as serious, they also provide a veritable tripod on which to fix their instrument, but the weaker makers compromise the situation by turning the tripod into a make-believe walking-stick. With such instruments as these the serious worker who "goes in" for a hand camera is more than content; but, between you and me and the tripod, dear reader, he was much better off with his honest tripod camera.

Other makers, again, crowd into their hand cameras all kinds of machinery, till they look as intricate, and bewildering, and dangerous as

the engine-room of a torpedo boat-destroyer. "Give us a long-focus hand camera," says one worker, "something with which I can take a distant view ten thousand miles away." And straightway he is supplied with an instrument as long and unwieldy as a coffin. "Oh, do away with those heavy double backs," says another; "I can only carry three of them, and that means limiting me to six pictures for an outing, whereas I want to take six hundred." And, presto! out comes some marvellous press-button roll-holder camera, warranted not to splutter. "But I must see the image full size, as I am taking it," says a third, "and I want to take only objects in motion on treble XXXXX rapid plates." So still more hand cameras are placed on the market, which depict a bird on the wing, a horse leaping a fence, or a man's leg in the air as he is walking along—anything and everything in the most awkward and ungainly of attitudes. I hope I have said enough to convince inquirers of the hopelessness of attempting to advise in the purchase of any particular hand camera. It depends entirely on the wishes and proclivities of the purchaser as to which he ought to buy, and there are designs now in the market to suit all tastes, from the most serious to the most frivolous, and all pockets, from those as shallow as mine, or, like those of my readers, deep, let us hope, as the Indian Ocean.

PHOTOGRAPHY OF COLOUR.

[Society of Amateur Photographers of New York.]

It would be presumptuous on my part to expect to present to you this evening much, if anything, entirely new pertaining to a subject to which so much careful study has been given for more than a quarter of a century, the fundamental principles of which, in fact, have been known ever since photography itself was discovered. It only remains for us to bring the many delicate and intricate details to a higher degree of perfection and to put them more completely under our control.

In order that we may proceed intelligently with the problems before us, I will briefly state the theory now held of the nature of light. The boldest assumption ever made by the scientist is that of the existence of an all-pervading ether, a nothingness, yet having such properties as perfect elasticity, no weight, continuity, filling all space not occupied by matter, &c. Time will not permit of the discussion of the nature of a scientific theory. Suffice it to say that no theory is of any value whatever which positively fails in a single test to which it may be put. In this, as in most cases, the proof is entirely negative—it cannot be demonstrated that such an ether does not exist, while, on the other hand, it enables us to account for a large number of phenomena, otherwise unexplained. So much, then, for the validity of the theory. The ether may be defined as that compilation of properties necessary for the explanation of the phenomena of light, electricity, and radiant heat.

The undulatory theory assumes that energy may be transformed into that state in which it may be propagated by the ether at the enormous velocity of, approximately, one hundred and eighty thousand miles per second, in the shape of waves, exceedingly small, but of definite dimensions. These waves are of the transverse kind, *i.e.*, similar to those on the surface of water, in which the vibratory, or up-and-down, motion is crosswise to the onward or propagatory motion. At present our knowledge of this wave motion is limited to a range of about eight and a half octaves, to use a musical term, an octave meaning the doubling of the number of vibrations. The eye is affected by less than one octave of these ether vibrations, the longest that can be perceived being about one-thirty-eight thousandth of an inch in length, and the shortest about one-fifty-nine thousandth of an inch. Light, then, is defined as that range of ether vibrations whose wave-lengths lie between these limits. I shall, presently, show, with the lantern, how the waves of different lengths affect the eye. For the present it will be sufficient, but important, to note the well-known fact, that the longest of these waves produce the sensation of red, the shortest, of violet, while those of medium length produce that of green. Now give your imagination full play for a few minutes, and picture every source of light, from this lamp to the blazing sun itself, as sending forth, along straight lines, in all directions, a subtle, palpitating set of waves, speeding on through space at a rate great enough to carry them more than seven times around the earth in a single second, and you have the theory in operation before you.

Perchance, a few of these rays enter the pupil of your eye and strike into that sensitive chemical of the retina, called purpurine, in which the optic nerve terminates. Is it any wonder that the delicate moleculea of this substance are shattered, and its rich purple bleached and faded, and that the nerve terminals in the midst of this disturbance recognise that something has happened? The mind simply says: "I see." This is the theory of vision. We are interested still further with this purpurine. Every one knows that the pupil of the eye dilates or contracts accordingly as the intensity of the light is less or greater. But the pupil is not the only regulator in this matter, as was formerly supposed, nor could it be, for the eye accommodates itself to a change of intensity, amounting often to more than a hundredfold, while the contraction of the pupil to, say, one-third of its former diameter (and that amount would be phenomenal) would compensate for less than a tenfold increase in intensity. It is now known that the amount of purpurine infused into the retina is greater as the quantity of light is smaller; in other words, the sensitiveness of the eye is made by this means to vary inversely as the quantity of light admitted approximately.

Thus the eye is a perfect camera, not only in its mechanical construction, but in its chemical action also, and is far more convenient, in that the sensitive film is not mounted on a glass plate or on a roll of celluloid; but the new sensitive material is constantly supplied and the old withdrawn without interrupting the operation of sight.

The theory of the vision of colour, assumes that there are three kinds of purpurine. One is susceptible to the action of the long waves of light, and, consequently, gives the sensation of red; this may be called the red-perceiving variety of purpurine. Another kind is affected by the short waves and gives the sensation of violet, and the third by those of medium length and produces the sensation of green; and these may be called the violet-perceiving and the green-perceiving varieties, respectively. Other colour sensations are produced when two of these varieties are acted on simultaneously; for example, the perception of yellow results when both the red and the green varieties are affected, and, when all three are acted on in the proper relative degree, the sensation of white is produced. One of the strongest arguments in favour of this theory is found in cases of colour blindness, in nearly all of which the result is just what must happen if the red-perceiving purpurine is absent; in a few cases the green-perceiving variety is wanting, either alone or along with the red. This is, practically, Young's theory of colour vision, but with this modification, that instead of his triple nerve terminals of different lengths and their mode of operation, which was simply mechanical, we have a purely chemical process, which is so analogous to photographic action as to demand careful consideration. Instead of assuming the actual existence of different varieties of purpurine, it would probably be more correct to attribute the several colour sensations to different characteristic modes of chemical decomposition of the purpurine by the various rates of etheric vibration.

The question as to what the primary colours are suggests itself in this connexion. We will define them as that fewest number of colours with which all possible varieties of colour may be produced; and these are red, green, and violet, and not, as is usually stated, red, yellow, and blue, notwithstanding the necessity of using red, yellow, and blue pigments to produce the whole range of colour, in printing or painting. Red, yellow, and blue ought not, however, to be called the primary colours, for neither the yellow nor the blue colour of a pigment is a simple colour, but rather a combination of two colours, in consequence of which green results when yellow and blue pigments are mixed or superposed.

I would urge the adoption of such a definition of primary colours as will avoid the necessity, and exclude the possibility, of there being two sets of primary colours; one set for coloured light, as such, and another for light from coloured pigments, for that is both confusing and unscientific. Since the spectroscope shows the colours from yellow and blue pigments to be complex, they cannot be considered primaries. The definition, then, should read: The primary colours are that fewest number of pure spectral colours which, singly and in varying combination with each other (or by their total absence), will produce the entire range of colour vision. Spectral red, green, and violet are these colours, and there can be no other primaries. A pure spectral colour, physiologically considered, is the colour sensation produced by a single limited section of the natural spectrum; for example, roughly speaking, the section from D to E is spectral yellow. In a physical sense, a spectral colour is a particular continuous range of wave-lengths, whose limits are largely determined by its physiological effect. On the other hand, a complex colour, as, for example, complex yellow, results when spectral red and spectral green are combined, and this may be either with or without spectral yellow.

The eye cannot distinguish between spectral and complex colours, but the spectroscope at once reveals their true nature.

The explanation of the colour of an object, it will be remembered, is that, when white light falls upon a body, some of the waves, the longer, or shorter, or medium ones, singly or combined, are absorbed and cease to exist as light, while the rest are reflected, and, being of particular lengths, produce a corresponding colour sensation. The colour, then, is not possessed by the object itself, but results from its power to absorb a part, and reflect the remainder, of the white light which strikes it. If

all the waves are reflected, the object is said to be white, as a piece of white paper or cloth; if none are reflected, but all absorbed, the term "black" is used to designate the absence of reflected light. A perfectly black hat, hung against a perfectly black wall, would be no more visible in broad daylight than in blackest night; but, as it is not possible to find a material which will reflect absolutely no light, such a result can only be approximated in the experiment.

In the case of transparent coloured bodies, a little further explanation is necessary. A piece of clear glass transmits the waves of light practically undisturbed, so far as their length is concerned, while a piece of red glass permits only the long waves to pass through it, at the same time absorbing the others; a green glass transmits only those of medium length, while only the short waves get through a violet glass. Of course, it is understood, these colours must be pure and saturated, conditions that can only be approximated in practice. Often the waves that do not penetrate are reflected from the surface on which they fall instead of being absorbed, and thus a large part of the set of waves is separated into two divisions, and the colour effect produced by one division is said to be complementary to that produced by the other, that is, the resulting colours are complementary.

It is evident from this that two complementary colours combined will produce white light, since, together, they contain the whole range of visible waves. An illustration of this kind of separation of light is found in common red ink. If a few drops are poured on a black surface, the ink will appear green; or, if allowed to dry on a pen or on the stopper of the bottle, they are coloured green. The inks used in printing coloured pictures, and many of the pigments used by the artist, are transparent materials, that is, a high degree of transparency is one of their most essential qualities, and, when these are spread on a white surface, the result is practically the same as laying on the surface a very thin piece of glass having the same colour. In both cases a particular part of the light only is transmitted to the white surface beneath, which reflects it, to be retransmitted and carried to the eye, so that the surface appears to have the colour of the transmitted light.

Let us assume, for the present, what will be proven later, that blue glass or blue pigment is blue because it transmits green and violet light, either with or without spectral blue, and that yellow glass or yellow pigment is yellow because it transmits green and red light, either with or without spectral yellow. Now, if a layer of blue pigment be superposed on a layer of yellow, but one colour will be able to pass through both, and that will be the one transmitted by them in common, that is, the green. Consequently, the production of green by the combination of yellow and blue pigments is not caused by a chemical action, but is a purely physical result. Neither does it argue in the least that yellow and blue should be considered primary colours. In the same way orange is formed by the combination of yellow and red, and purple, from blue and red; and, furthermore, it is evident that, if red pigment is superposed with yellow and blue, all the light will be absorbed, and the surface becomes black.

We are now ready for the explanation of the method of making a coloured picture by, what has been termed, the tricolour process. Let it be understood that the problem of coloured photography cannot be admitted into our discussion this evening. It remains, up to the present, practically unsolved, and bids fair to baffle the scientist for some time to come, notwithstanding it has been the fondest dream of the photographer for more than half a century to reproduce Nature in all her varied hues. The photography of colour, however, is a very different thing, and is quite practical. It constitutes the first, and perhaps the most important, part of the tricolour process. I may assume that all who are associated with this Society are familiar with the operations of making an ordinary photograph, and have carefully studied that all-important thing, a negative, which is simply a film rendered opaque in some parts, quite transparent in others, and having all degrees of sub-transparency ranging between. This negative is a miniature reproduction, perfect in form, but without any of the colour of the original.

Now, for our present purpose, we will group all the colours in any subject we may wish to make a picture of into five classes, viz., the blacks, reds, yellows, blues, and whites. It is understood that each of these so-called classes is supposed to contain what would correspond to one of the effects of coloured pigment ingredients if the original had been produced by the use of red, yellow, and blue pigments, *i.e.*, each class contains a particular colour, not only when it is pure and uncombined (in which condition it might be absent altogether), but also when combined with one or both the others, in large or small quantity, and no matter how thoroughly disguised. A careful examination of a common negative shows that the transparent parts correspond to the blacks, reds, and yellows in the original, while the opaque parts correspond to the blues and whites; the whites because of the blue in them. This means, then, that only the blue, or, more properly, the blue-violet, light produces the opacity in a common negative. When a black-and-white monochrome or ordinary photograph is made, its light and dark regions are just the reverse of those in the negative, so that the light parts of the photograph represent the whites and blues in the original, while the dark parts represent the yellows, reds, and blacks. This monochromatic representation of colour is strongly objected to by the artist, and with good reason, as I will show a little later. Results very different from that obtained on an ordinary plate, with the usual methods of exposure and development, may, however, be had under special conditions. Most important among these are the so-called sensitisation of the plate and the filtration of the light. Notwithstanding the interesting results of Mr. Ives's experiments on the sensitisation of the ordinary plate, published some time since, which seem to show that, with proper filtration of light, photographic action may be obtained from any part of the spectrum, yet, in practice, it is necessary to make use of sensitisation. The methods of sensitisation and the results it produces may be clearly stated, but not so when it comes to explaining what the nature of the effect produced on the plate really is.

The violet end of the spectrum acts generally as a reducing agent, while, on the other hand, the red end often shows a tendency to act as an oxidising agent, under ordinary conditions. However this may be, one of the essential properties of a sensitiser is chemical in its nature, and such as to enable it to appropriate to itself, and dispose of, the oxidising tendency of the red end of the spectrum. Another very important, if not indispensable, property is physical in its nature, the so-called optical property, *i.e.*, to be most effectual, the sensitiser should absorb only that colour the photographic effect of which is desired, the remainder being reflected, which means that the colour of the sensitiser is complementary to the colour to which the plate is to be rendered sensitive; thus, cyanine and malachite green sensitise to red, and erythrosine and methyl violet sensitise to yellow, &c. When the kind, extent, and degree of sensitisation are determined, the problem of filtration is quite simple.

The filter must be chosen with reference to the condition of sensitiveness. Many experimenters make a serious mistake at this point by assuming that, because the end in view is to obtain three photographs, one of the red, another of the green, and another of the violet colour ingredient (in the case of a lantern picture), they must needs use ray filters of corresponding colours. Such filters would perhaps be the correct ones to use if there could be produced in the plate a perfectly uniform and continuous sensitiveness throughout the entire visible spectrum. It is doubtful, however, if such a condition is at all desirable. Various sensitisers may be made to produce maximum sensitiveness in one or more particular regions of the spectrum without, as a rule, appreciably diminishing any sensitiveness previously possessed by the plate. If, then, sensitiveness is produced in regions where it is desired to have it, there will generally be one or more other regions also sensitive, and it is the function of the filter to cut out the one or more other colours to which the plate is sensitive, but which it is desired should not produce an effect. For example, if a plate is rendered sensitive to green, it will still be sensitive to blue and violet, and, in order that it may photograph green only, the other two colours must be cut off; consequently, any filter which will transmit green but not blue and violet will do equally well, *i.e.*, it may be a yellowish green, or a yellow, or even an orange, and the result will be the same. Or, again, if a plate is rendered sensitive to yellow, it will retain its blue-violet sensitiveness, which makes it necessary to cut off the blue and violet, if the yellow is to be retained alone, and, as before, a yellow, or orange, or orange-red filter will give, approximately, the same results. Cyanine produces sensitiveness in regions of the yellow and orange, and well into the red, so that, with the natural blue-violet sensitiveness, all the spectrum, except the green, region, is sensitive; consequently, it is not strange that almost any red filter, which does not transmit blue and violet, will give about the same result. This red filter may transmit much, or little, or no green, without modifying the result in the least, and yet the difference in appearance to the eye, resulting from the transmission of more, or less, or no green, is exceedingly great. No other explanation than this is necessary; nevertheless, some of the best-known experimenters pronounce it paradoxical that red filters, of different quality, give practically the same results. The question is not so much, What shall the ray-filter admit? as, What shall the ray-filter exclude? Of course, it must admit the particular colour whose effect it is desired to obtain. It follows from this that with the usual methods of sensitisation, no matter what the result desired, there is positively no need whatever of a green filter.

PROFESSOR J. STEWART GIBSON.

(To be continued.)

PHOTOGRAPHING ANIMALS TO SCALE.

Mr. W. I. Chadwick's plan of utilising photography for the purpose of obtaining photographs of animals taken to scale is described by himself as follows:—

As is well known, photographs of animals are practically useless for purposes of measurement, owing to the effects of perspective, ignorance of the distance of the point of sight, and the general absence of comparison with objects of known dimensions. The object of my said invention is a definite process or procedure having known conventional constants, and the introduction of a comparison scale into the photographs for purposes of measurement or estimation of the dimensions of the animal.

For example, in making photographs of horses according to my said invention, I use a lens of known focus, fixed at a known height above the ground and at equal or proportionate distances from certain fixed marks in the ground. The horse is brought in front of the lens and over the indicating marks on or in the ground. The position of the horse's feet with respect to such marks is noted either by eye observation or by examination of the photograph.

Subsequently, with the lens still in the same position with regard to the indicating marks, a screen, having horizontal and vertical bars, subdivisions, or graduations, is placed on the line running between positions previously occupied by the fore and hind feet of the horse. A photograph of this screen is taken, and by double printing, superposition, or combination, the two photographs of the screen and the animal are combined into a single photograph. Owing to the procedure adopted, the vertical plane of the screen will coincide with a vertical plane through the spine of the animal, and, partaking of the same effects of perspective projection, the contour of the animal may be quantitatively noted, and reliable comparison of what are known to breeders as "points" may be made between photographs of animals taken at different times and places. According to a modification of my said invention, a screen, or graduated framework is placed about the animal in a plane passing through its spine, and is photographed simultaneously with the animal.

SEAMAN'S PRINTING FRAME FOR STAMP PHOTOGRAPHS.

Mr. Edward Seaman has patented a printing frame to print twelve photographs, each one inch by three-quarters of an inch, on one piece of prepared photographic paper three inches square. The frame consists of two slides. One contains a hole, one inch by three-quarters of an inch in size, which is the size of the photographs, made in such a manner that a negative may be fixed behind it; the other slide contains a hole three and a quarter inches square. The paper is laid on a ledge, which goes round the hole, and fixed by means of the back. The slides are grooved, so that when fitted together each one may be moved to and fro. By this movement the paper is brought into position behind the negative, and is exposed by the frame being held up to a light. The slide is moved again to change the position of the paper, and then it is again exposed. This is repeated until twelve exposures have been completed, thus producing twelve separate photographs on one piece of paper.

HODDLE'S APPARATUS FOR MOUNTING PHOTOGRAPHS.

Mr. Charles Hoddle's description of his invention for mechanically mounting photographs is as follows:—

I provide a drum or cylinder, mounted in any suitable manner, and adapted to be rotated either continuously or intermittently, and to receive the wet photographic or other prints, which are placed face downwards thereon, preferably by hand, a roller being provided for partially drying the prints and pressing them on the drum or cylinder.

In any suitable position in the path of the drum or cylinder I provide a receptacle to contain paste or other adhesive material, the said receptacle having an opening through which the paste escapes on to the back of the photographic or other print as the latter passes under the opening. The opening of the receptacle is provided with an indiarubber or other suitable squeegee or scraper for spreading the paste evenly over the back of the print. I further provide a case or receptacle for the mounts, and means for feeding the same one at a time down through an opening or slit in the bottom of the receptacle on to the periphery of the drum. An indiarubber or other roller is placed underneath the said slit or opening, so that the mount is held firmly against the periphery of the drum, and the movement of the mount is so regulated that it arrives opposite the said roller at the same time as the corresponding print, whereby the latter is firmly pressed on to the mount, and is caused by the paste to adhere thereto. A second pair of rollers is preferably provided, through which the mounted photographic or other print passes.

For feeding the mounts through the opening in the box or case containing the same I advantageously mount a face cam on the drum or cylinder spindle, or I form the same on the end of the drum, the said cam actuating a lever which reciprocates a slide, the said slide forcing the mounts one at a time through the slit or opening in the box containing the same.

Our Editorial Table.

The "Sweetheart" Adhesive Cloth.

Marion & Co., Soho-square.

This is a thin cloth, one side of which is coated with an adhesive substance, thus admitting of the rapid mounting of photographs. It is pointed out that, among others, reduction in weight and bulk, perfect protection against tearing or cracking, without the necessity of using a rolling press in mounting, are some of the advantages which may lead to its general adoption. The following are the directions for use:—"Place the photograph, face downward, upon a sheet of paper larger than the cloth, place the brown (coated) side of the adhesive cloth upon the back of the print, apply an ordinary flat iron, moderately hot, to the back of the cloth, and press well in contact with the print. If preferred, a hot roller press can be used for this operation, in which case it is only necessary to pass the print with the cloth once through the rollers." Many opportunities, doubtless, arise in both professional and amateur practice when it is advantageous to mount prints on cloth supports, and the "Sweetheart" cloth supplies quite the thing for the purpose.

The Perfectus Sensitised Albumen Paper.

The Perfectus Sensitised Paper Co., 38, St. John's-park, Blackheath, S.E.

We remarked, last week, of celluloid films, that a determined effort was being made to popularise them among photographers, and the same observation holds good with regard to sensitised albumenised paper, in which many photographers and some manufacturers appear still to retain great faith. The above-named Company sent us, the other day, some pieces of the "Perfectus" paper to try, which yielded us prints of great richness and evenness. The "Perfectus" paper appears to have been well made and liberally sensitised, and is as good a paper of its kind as we have tried.

The Parastudio.

W. Watson, 130, West Graham-street, Glasgow.

A rough model of the Parastudio has been submitted to us for inspection by its inventor, Mr. W. Watson. It is intended for controlling the light in outdoor portraiture. It may briefly be described as consisting of a light metal tripod stand with a species of umbrella attached, which is adjustable at various angles. The whole thing by the aid of a fabric adapter can be converted into a tent. The Parastudio embodies a good idea, and for garden portraiture should be found useful in controlling the light as circumstances dictate.

The Austin-Edwards Films.

Austin Edwards, Willoughby-lane, Park, Tottenham.

Mr. Austin Edwards has lately asked us to subject some of his Double Instantaneous films to trial, and the result of having exposed and developed them is to confirm us in the opinion we expressed of them when they were first introduced, nearly two years ago, namely, that they possess great speed, combined with the power of resisting fog, even under strong or forced development. The emulsion is fine in the grain, and the preparation of the films throughout is evidently accomplished with great care. Among those who cater for the supply of cut films, Mr. Austin Edwards deserves to take a prominent place, and it will not be the fault of his films if he does not retain it.

Catalogues Received.

Joseph Levi & Co., 97, Hatton-garden, E.C.

Messrs. Levi's catalogue is an elegant production of over 130 pages, and, between its covers, it is difficult to discover that any modern requirement in the way of photographic apparatus has been denied mention. The catalogue, in addition to its completeness, has the further merit of being well illustrated.

W. Butcher & Son, Blackheath, S.E.

Messrs. Butcher's catalogue is largely a *résumé* of the firm's own specialities, of which, as our readers are aware, they have many. For the rest, a large selection of apparatus and sundries is recapitulated and illustrated.

Reduco.

Arthur Harrison, 221, Cowbridge-road, Cardiff.

This is a pink-coloured, ointment-like mixture, which, upon being applied gently with a leather stump or a soft cotton rag on the ball of the finger to the too dense or halated parts of a negative, will effect the desired degree of reduction. We have tried Reduco, and found it answer its purpose.

News and Notes.

We are informed that the Oxygen Compression Works of Messrs. Leonard Chapman & Co., Sheffield-street, Lincoln's Inn-fields, W.C., have been acquired by Mr. Walter Tyler, of Waterloo-road, S.E.

It will be seen, from an announcement made in our outer columns, that, in future, packages of dry plates will be obtainable at the railway bookstalls of Messrs. W. H. Smith & Sons. Doubtless, many amateur photographers and others will much appreciate this convenience.

Paisley Photographic Society.—The following are the office-bearers for 1896-97:—*Hon. Presidents:* Messrs. H. H. Smiley and Stewart Clark.—*Hon. Vice-Presidents:* Messrs. Robert Harris, James Donald, jun., James Barr, and A. F. M'Callum.—*President:* Mr. Edward Cook.—*Vice-President:* Mr. Thomas Rastall.—*Council:* Messrs. D. B. Jack, F. Matheson, J. Gibson, J. Mure, C. Glassford, M. M. Wright, and J. M'Kinlay.—*Treasurer:* Mr. Robert Pitblado.—*Secretaries:* Messrs. Robert M'Kinlay, Wallace Lea, Glasgow-road; and Robert Alexander, 2, Gordon-place.

Enlarging on Canvas.—In the *St. Louis and Canadian Photographer* the following method of enlarging upon canvas is given:—Wash canvas in hot water, rinse with cold, after which stretch to remove all folds. Salting solution: Potassium bromide, 3 parts; potassium iodide, 1 part; cadmium bromide, 1 part; water, 240 parts. Thoroughly saturate the canvas with this, and hang in a warm room to dry. Then sensitise with nitrate of silver, 4 parts; citric acid, 1 part; water, 140 parts. Sensitising is done same way as salting. Expose in solar camera, or in a similar camera illuminated by electric light. Develop the exposed canvas in pyrogallic acid, 10 parts; citric acid, 4 parts; water, 410 parts. Use slightly warm, and about 10 minutes are necessary to bring out the picture, thoroughly washing after development. Tone same way as silver prints, with acetate of soda and gold. Fix in hypo-sulphite of soda.

The law of copyright in this country has occasionally been strained unjustly in cases which it was hardly intended to cover, but in America it is apparently a power which can be used almost to the extent of persecution. Messrs. Harper Bros., the publishers, of New York, have recently entered an action against Messrs. Riley Bros., of Bradford and New York, the well-known optical lantern outfitters, which certainly puts the American copyright law in a very unfavourable light. When the popular story *Ben Hur* was printed by Harpers, they reserved all rights to the publication and dramatisation of the novel, and afterwards sold the dramatisation rights to Messrs. Clarke & Coxe, a Western firm. Messrs. Riley, at considerable expense, have prepared an illustrated lantern lecture on the story, and Messrs. Clarke & Coxe now object to this as an infringement of their rights of dramatisation, and claim damages to the tune of 10,000 dollars. The case had not come to a hearing when the latest advices were received.—*Bradford Observer.*

The statement is interesting, as coming from Professor William Huggins, foremost in such researches, that beyond the violet end of the spectrum there is a whole gamut of invisible rays, which only reveal themselves by their effect in promoting chemical action, and similarly, beyond the other end of the visible scale, the deep red, there is a gamut of invisible, or dark, rays, which are only perceived by their heating effects. Some idea, he says, of the importance of the "ultra red" may be gathered from the fact that it has been traced to a distance nearly ten times as long as the whole range of the visible, or light-giving, region of the spectrum. To learn, then, the character of these mysterious dark rays, it has been clearly necessary for science to fit itself with some new sort of eyes for seeing what ordinary eyes cannot, namely, heat rays and chemical rays; and, in respect of the latter, the photographic plate has brought out some wonderful facts, while the bolometer has been used in feeling for absorption lines in the great invisible spectrum which lies beyond the red.

The Glasgow "Evening Times" Annual Photographic Exhibition.—This Exhibition will have classes for amateurs and professionals. Thirteen silver medals, thirteen bronze medals, and certificates will be awarded. The Exhibition opens August 3, and closes August 29. Pictures are to be sent in on July 15, 16, or 17. Classes for amateurs only: I., II., III. Landscape or Seascape. IV. Portraiture or *Genre* Study. V. Hand-camera Work. VI. Architecture. VII. Novices' Work. VIII. Lantern Slides. IX. Stereoscopic. X. Enlargements. XI. Champion Class. Classes for professionals only: XII. Portraiture or Figure Studies. XIII. Landscape or Seascape. All pictures must be sent in to the Rooms of the *Evening Times* Camera Club, 46, Gordon-street, Glasgow, on one or other of the following dates: July 15, 16, or 17. On each of those days the Rooms will be open from twelve o'clock noon to nine p.m. for the reception of pictures. Correspondence relative to the Exhibition should be addressed to Mr. H. C. Shelley, *Evening Times* Office, Buchanan-street, Glasgow.

Röntgen Ray Phenomena.—Mr. J. William Gifford writes to *Nature*: "At one of my demonstrations last week two tubes failed to act. They were both of the kind which depend for their action on a piece of platinum placed within, and from which after bombardment by cathode ray the Röntgen rays take origin. A glance at the tubes showed that, owing to the unusual strength of spark, the platinums within them were red-hot at the point of impact. Before the demonstration the tubes had been in good working order. I considered they had broken down, but, on returning home, tried them with the spark from my own apparatus, with which they had before answered well. I was somewhat astonished to find them giving off Röntgen rays rather more freely than when first tried. This tends to show that Röntgen rays are not given off by platinum heated above a certain temperature. I think this has already been suggested, but I have not seen it corroborated. Following up the idea of reinforcing the effect of the Röntgen rays by placing a fluorescent screen under a sensitive film on celluloid, the celluloid side being next the screen to prevent "grain," and having tried screens of barium platino-cyanide, potassium platino-cyanide, calcium tungstats, natural scheelite, artificial scheelite (Edison's), fluoro spar and calcium fluoride, I find that potassium platino-cyanide and artificial scheelite alone produce any effect through celluloid. Barium platino-cyanide, placed underneath, gave no effect either in contact with the sensitive film itself or through celluloid, but the films were not sensitive to yellow, and this salt gives yellow fluorescence. The effect with potassium platino-cyanide was decidedly the best."

A New Type of Telescope.—A very important discovery has been made by Professor C. S. Hastings, of the Yale Scientific School, the result of which is a new type of telescope, in which the defect known as the secondary colour aberration is removed without the use of other than the ordinary silicate glasses, says the *Evening Post* (New York). In developing last summer the optical equations involving the thickness and separation of lenses to the second order of magnitudes, Professor Hastings found a term which might be of the opposite sign to that involved in the equations of colour correction. Although it seemed improbable that this would afford a means of correcting the old error, it demanded, in the Professor's opinion, further investigation. After much labour he demonstrated theoretically a new method by which the secondary chromatic aberration, which had resisted solution for almost a century and a half, might be remedied. He next constructed a telescope with a ratio of focal length to diameter of only eight and a half, for use with the spectroscope. This has fulfilled in every way the hopes founded upon the theoretical investigation. It shows the solar spectrum with absolutely unvarying focus from extreme red to extreme violet, eliminating all secondary colour aberration. While the experiment has not gone beyond this, there is no reason to doubt that the method is applicable to telescopes of all sizes. Several years ago Professor Hastings published a construction involving a lens of but two kinds of glass, which very nearly met the desired end; but it has proved impossible to obtain large pieces of glass of the required kinds, and thus the method has been confined to small telescopes. It is an interesting historical fact that Fraunhofer, while endeavouring to solve this same problem, discovered the lines of the solar spectrum which bear his name. The discovery of Professor Hastings will add at least ten per cent. to the power of the telescope, so that an instrument with a ten-inch object-glass will be about equal to an eleven-inch telescope of the existing type.

A Great German Telescope.—The Berlin Industrial Exhibition opened May 1, and, in connexion with it, the Astronomical Observatory of Grunewald will be transferred to Treptow, near Berlin. One of the features of the Exhibition is that of photographs of old instruments, models of telescopes, reproductions of astronomical drawings and kindred subjects. As the largest refractor hitherto erected in Germany has only been one of eighteen inches' aperture, it is gratifying to note that one is now being constructed having an aperture of twenty-eight inches. The mounting is so arranged as to receive two objectives, of which one is designed for direct visual, the other for spectroscopic and photographic observations. For this reason the latter will be a double objective of short focal length, twenty to twenty-three feet, and large aperture, forty-three and one-third inches, which, for the present, will be exhibited in an unfinished condition, as the means for the purchase and polishing of the enormous lenses, which have been very successfully cast by Dr. Schott, can only be raised during the Exhibition. The rough discs of glass for the lenses of the telescope have been furnished by Dr. Schott and Gehrcsser, of Jena, while the polishing has been executed by Messrs. C. A. Steinheil, of Munich. The mounting of the instrument was intrusted to the Berlin Maschinenbeau Anstalt C. Hoppe, "who were assisted" by the firm of G. Meissner, Berlin, in the execution of the minute mechanical portions. The other objective, on the contrary, is completed, and has an aperture of twenty-seven and a half inches, and a focal length of sixty-eight feet. Instead of the usual dome, the telescope is provided with a cylindrical protective envelope, which, together with the tube, is mounted on a rigid box, which can be rotated round the declination axis. The polar axis is placed in the interior of the pier. Attached thereto, and therefore revolving round it, is a kind of bell, which encloses the observer's seat. The above-mentioned box revolves with the bell round the polar axis. The observer sits in the prolongation of the polar axis, in such a manner that his head is in the turning point of the whole telescope, so that he can easily follow its movements by slightly turning his head. The counterpoises for the tube extend at either end of the box, besides which there is attached a second bell, which serves to relieve the polar axis, and for this purpose runs on two anti-friction rollers fixed to the pier.

Affiliation of Photographic Societies.—Twenty-fourth Meeting of Delegates, held at 12, Hanover-square, on Thursday, May 21, 1896, Mr. W. Thomas (Chairman) presiding.—The Secretary gave the approximate figures of expenditure and receipts for the series of lectures just completed, which showed that, as far as could be seen at present, the lectures would have cost between 11*l.* and 12*l.* (after deducting sums received for tickets). After some remarks by the Chairman, a vote of thanks to M. Demachy was proposed by Mr. Oakden (South London), seconded by Mr. Huddy (Richmond), and carried. On the proposal of Mr. Panting (Woolwich), seconded by Mr. Beckett (Hackney), a vote of thanks was carried to Royal Photographic Society for the use of their rooms for the lectures. It was proposed by the Chairman, seconded by Mr. Oakden, and carried: "That the thanks of the Affiliation be given to Captain Abney, and Messrs. J. A. Sinclair, W. E. Debenham, J. D. Geddes, and W. T. Wilkinson for their lectures." The

Chairman suggested that a series of illustrated lectures should be prepared for circulation, and it was proposed by Mr. Oakden, seconded by Mr. Hertslet (North Surrey), and carried, "That the Affiliation Committee provide a certain number of special papers, illustrated by slides or otherwise, on various photographic subjects." After some discussion it was agreed that Messrs. Beckett, Hertslet, Mackie (Royal Photographic Society), Oakden, and Panting be appointed a Sub-committee to make the necessary arrangements for carrying this resolution into effect, the following subjects being suggested: Elementary papers upon lantern-slide making, pictorial photography, enlarging, architectural photography, photographic optics, printing methods, hand-camera work, and negative making. Mr. Oakden said that a desire had been expressed that the Committee should help the country societies, when desired, to arrange for lecturers. The following resolution, which was passed on February 24, 1894, was read: "That an offer should be made to assist local societies in the way of lectures if two or more of them could temporarily amalgamate for the purpose." It was agreed that the Committee already appointed should be instructed to take the necessary steps for carrying out that resolution, which, it was agreed, should apply to individual societies as well as to more than one society. The resolution of May 9, 1894, with reference to the circulation of a set of slides of Rejlander's work, was rescinded on the proposition of Mr. Bridge (Photographic Club), seconded by Mr. Marchant (North Middlesex). A desire was expressed that there should be another conference of Secretaries, and it was pointed out that the Secretaries of metropolitan societies had arranged with the Secretary that they were to be called together upon the application of any three Secretaries. It was agreed that the Chairman should make the best arrangements he could for the publication in pamphlet form of the series of lectures on the bichromate salts, with the stipulation that 200 copies should be supplied to the Affiliation for the Societies.

THE BUSINESS END OF THE QUESTION.—In the discussion of the question of emulsion *versus* albumen paper for printing photographs, the business view of the question, to those who aspire to raise our profession as much as possible out of the mire, financially and otherwise, has, so far, been ignored. Even granting that the question of relative permanence of results has not been determined, I would like to ask the better class of photographers on which side their bread is buttered? Is it on the side that puts the product in its qualities, after the negative gets to the printer, on a dead level with every tinkerer and cheap John who buys the same paper, or in adopting one where each photographer puts his own individuality in that, as he does in his negative? I have already proved, by our own experience, that the old method saves labour, both in the toning and washing operations, and in the finishing, and is therefore, in that sense, cheaper. But it is also true that in emulsion papers there is no latitude of treatment. Each paper must be treated by the method recommended by the makers; and those who would avoid trouble must see their prints exactly like those of every one who uses that paper. Whatever is made easy and mechanical is one more nail in the coffin of fair prices for superior skill and taste. On the contrary, the results on albumen paper, though always good in first-class hands, can be varied to suit each individual taste. One may like very warm tones; the other very cold tones, black and gray; another the medium between the two; yet all be equally good, according to the taste and skill employed. One may like strong negatives and a weak silver bath; another more delicate negatives and a strong bath. Both may yield excellent results, and yet differ entirely in character. One may like the purplish tones of the acetate bath; another the neutral warm black of the lime bath (in my opinion the most artistic of all); another prefers the brown and blue-black of the simple bicarbonate of soda bath. In none of these cases can exact imitation be followed by the cheaper class of men, but only by those with equal skill. In all the emulsion papers, the hard steely whites produced by the enamelled paper forming the support are in evidence where the negative is much stronger than a mud wash, and, wherever the toning is pushed in the least beyond a certain limit, we have the horrid effect of cold tones in the half-shades, with warmer colour in the deep blacks, while every artistic instinct points the other way; and no matter how strong may be the negative, unless it represents nothing but black and white, the albumen print always has a softer and more fleshy effect in the whites, an effect distinctly different from most emulsion prints, and by which the high-priced man can show his patrons that his work is not like his dollar or two dollar a dozen neighbour, who buys ready-made and ready-cut print-out papers. It is much more easy to convince people when the tones and surfaces of your prints are not like those of the host of photographers who put themselves, so to say, in the hands of the manufacturers. In other words, what is for the benefit of the unskilful and ignorant in our business is to the detriment of those who are of the better class. The dry plate was already a step in the levelling direction, yet its advantages compensated for it; but these papers, while incalculably more levelling, certainly show no compensating advantages so far, and, if we can save ourselves from the inevitable result, an intelligent self-interest justifies our doing so.—D. BACHRACH in *Wilson's Magazine*.

Patent News.

THE following applications for Patents were made between May 13 and 20, 1896:—

PHOTOGRAPHIC APPARATUS.—No. 9935. "Improvements in Apparatus for Developing, Toning, and Fixing Photographic Plates, Prints, and Films." J. G. WILLIAMS.

AUTOMATIC INDICATOR FOR SLIDES.—No. 10,030. "An Automatic Indicator for Photographic Dark Slides." J. B. SINCOCK.

KINETOSCOPE.—No. 10,033. "Improvements in the Photographic Reproduction of Moving Objects." S. D. WILLIAMS.

URANIUM INTENSIFIERS AND REDUCERS.—No. 10,072. "Improved Uranium Intensifiers and Reducers as applied to Photographic Negatives and Positives." A. HILL and THE CRESCO FYLMA COMPANY, LIMITED.

PHOTOGRAPHIC MAPS.—No. 10,118. "An Improved Mode of obtaining Photographic Maps and Earth or Ground Measurements." Communicated by A. Nobel. A. V. NEWTON.

DEVELOPING SOLUTION.—No. 10,157. "An Improved Apparatus for the Distribution of Solutions in the Development of Photographs and for other like purposes." F. C. BRIGGS and L. M. ISAACS.

LANTERNS.—No. 10,194. "Improvements in Optical Lanterns." J. RILEY, W. RILEY, and H. DALBY.

FILM-HOLDERS.—No. 10,217. "Improvements in Frames or Holders for Photographic Films." F. ANDREAE.

PLATES.—No. 10,242. "Improvements in the Production of Photo-chromatic Plates for General Printing Purposes." W. HAYWARD.

APPARATUS.—No. 10,495. "Improvements in or Relating to Lenses, Sensitive Films, and Cameras for Photographic Purposes." W. FRIESE GREEN.

LENSES.—No. 10,518. "Improvements in Lenses for Photographic Purposes." R. KRÜGENER.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

June.	Name of Society.	Subject.
1.....	North Middlesex	Informal Meeting.
1.....	South London	*The Improvement of Negatives.* H. J. Dalby.
2.....	Brixton and Clapham	Ordinary Meeting.
2.....	Gospel Oak	Judging of the Competition Pictures taken on May 9.
2.....	Hackney	*Lighting.* W. E. Debenham.
3.....	Borough Polytechnic	*Lantern Slides, their Production and Use.* W. Wade.
3.....	Edinburgh Photo. Society	Election of Office-bearers and Council for Session 1896-7.
4.....	Leeds Photo. Society	*Some Notes on the Use of Orthochromatic Plates, with and without Screens.* S. A. Warburton.
4.....	London and Provincial	*Stops. f-2.* P. Everitt.
5.....	Aintree and District	Stereoscopic Photography.
6.....	Borough Polytechnic	Excursion: High Barnet.
6.....	Hackney	Excursion: Leigh. Leader, C. A. Russell.
6.....	Liverpool Amateur	Excursion: Ingleton. Leader, J. T. Norman-Thomas.
6.....	Oldham	Exc.: Alderley. Leader, J. Fullalove.
6.....	South London	Excursion: Edgware and Whitchurch. Leader, W. C. Boyce.
6.....	West Surrey	Excursion: Kew Gardens.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 21.—Mr. W. D. Welford in the chair.

A letter was read from Mr. E. J. Wall, who was to have read a paper before the Association, saying he was prevented from fulfilling his promise on account of the death of his mother.

It was proposed by Mr. FRESHWATER that the condolence of the members be conveyed to Mr. Wall in his bereavement, seconded by Mr. BEDDING, and carried unanimously.

Mr. A. L. HENDERSON brought up a quantity of developer, the constituents of which were not mentioned, and asked some of those present to try it against any other developer and report the result.

THE NEW PHOTOGRAPHY.

Mr. T. BEDDING had had a communication with reference to fluorescence of plates, which stated that, instead of using a screen of platino-cyanide of potassium for visual use with the X rays, one might substitute a gelatine dry plate, which answered in the same way. He inquired if anybody could confirm this, and said, if it could be done, it would probably account in some measure for the action of the X rays on gelatine dry plates.

Mr. T. E. FRESHWATER did not think in the ordinary way any fluorescence could be got from a plate. He had been going into the subject, but had failed to notice any trace of such an occurrence. It was said that the action of the rays was due to the fluorescence from the glass, but this he doubted. He would also like to see proved the assertion that a plate exposed to these rays developed from the back instead of the front surface. His experience pointed to the contrary, the image coming up in the usual manner. He did not think it was anything to do with the glass, as one got the same result with films, whether they were thick or thin.

Mr. HENDERSON inquired how the screens were produced. Those he had seen were very rough.

Mr. FRESHWATER said the paper was coated with the crystals with the aid of some tacky substance, but the process was kept somewhat secret. There was a screen which was quite smooth; but, whatever it consisted of, it did not give the amount of fluorescence obtainable with potassium platino-cyanide.

SCUM ON NEGATIVES.

Mr. BEDDING asked Mr. Henderson what was the cause of the scum on negatives in the form of irregular serpentine markings, which were often to be seen many years ago on gelatine plates. He had recently heard it put down to hand coating.

Mr. HENDERSON replied that the probable cause was simply the superheating of the emulsion, and suggested a remedy in allowing the temperatur

to go down and filtering through washleather. He said it could all be got off the negative with a little friction, but, as the exposure was made through the scum, there would remain transparent marks.

Mr. BEDDING pointed out, however, that the marks he referred to were not visible until the negative was dry. He had not encountered them at all until lately.

Mr. J. E. HODD inquired how long a piece of bromide paper should remain good if properly kept, and whether a manufacturer was justified in declaiming responsibility because the paper had been made five months ago.

The opinion was that it should last indefinitely.

The CHAIRMAN mentioned a new reducing medium which would soon appear. It resembled cold cream, and was used upon the negative in a dry condition by means of a wad or stump, the density being reduced by gentle rubbing. He did not know its composition.

Mr. BEDDING suggested that it probably consisted of fine pulverised pumice in some greasy vehicle.

Mr. HENDERSON thought this likely, but asked, Why play about with such things when you have ferricyanide and hypo—a perfect reducer?

A discussion occurred as to why a plate appeared denser when wet than dry; why drying by heat gave a denser negative than when done naturally; and as to the reason for a black developed negative drying green.

Mr. HENDERSON made a statement, as delegate of the Association to the Convention, with reference to his alleged grievances against the Council of the Convention, and his future attitude towards that body, giving details of the reasons for the breach between himself and the Convention.

On the proposition of Mr. BEDDING, seconded by Mr. FRESHWATER, it was resolved, "That this meeting expresses its confidence in Mr. A. L. Henderson, as delegate of the London and Provincial Photographic Association to the Photographic Convention of the United Kingdom," for which Mr. Henderson expressed his thanks.

PHOTOGRAPHIC CLUB.

MAY 20.—Mr. Naegali in the chair.

Mr. Welford passed round a series of photographs made with a hand camera similar to that shown by Mr. Hodd at a previous meeting. The results were good.

Mr. BEDDING drew attention to some negatives which he passed round. He asked for some explanation of the scum marks which showed upon the surface of the film. Various points were raised, and the general conclusion was that the peculiarity was probably inherent in the method of manufacture of the emulsion.

Mr. Tottem showed some pieces of gelatine printing-out paper which had a curious white mark in the centre of each sheet. This had the appearance of an oval patch, which was whiter than the rest of the paper, and which could be more clearly seen on the back than on the coated side. No probable explanation of the phenomenon was forthcoming.

Mr. WELFORD asked if any member had tried the new reducer, which was in the form of a "pink grease," and which could be locally applied. He had found it to reduce the yellow negative deposit caused by pyro soda, a feat which was difficult of accomplishment at any time.

Mr. CHILD BAYLEY then read his paper upon

PHOTOGRAPHIC SOCIETIES AND PHOTOGRAPHIC ART.

Mr. Bayley, in opening his subject, said that one of the first papers read before the now Royal Photographic Society, about the year 1853, was upon the subject of art in photography, and that many persons had been writing upon the same subject ever since. He had read much that had been published on this subject, and he ventured to say that he believed he was right in asserting that everything which was worth writing could be found in either Burnett's *Essays* or Robinson's *Pictorial Photography*. In most cases these authors had expressed their ideas more happily than their imitators and extractors. Dealing briefly with present-day writers upon photographic art matters, the author of the paper, without descending to personalities or mentioning names, applied a good deal of humorous, if sarcastic, comment, and closed an interesting paper with the statement that the best way to further photographic art was to have a frequency of Exhibitions containing the best work of every school displayed, so as to show it to the best advantage.

In discussing the paper, Mr. BEDDING stated that, although Mr. Bayley had disclaimed any other position as the author of the paper than that of a member of the Photographic Club, he could not help regarding it as a plea for the Royal Photographic Society *versus* the Salon. In brief, Mr. Bayley's contention was, that we should make photographs and not talk about them; but he, Mr. Bedding, thought that the various papers which had been written upon art in connexion with photography (even by people who possibly knew very little about it) had done some good, small as it might be. He said that critics had been described as persons who had failed to produce successfully; but one of the functions of persons who write and criticise is to point out where failure exists. Knowledge cannot be acquired without this iteration, and reiteration, of which Mr. Bayley had complained in his paper. How was art knowledge to be spread if Mr. Bayley's advice were followed? Mr. Bayley, in his paper, had judiciously omitted to refer to the split which had taken place in the Society a few years since; but, in referring to it himself, he would say that he thought the cleavage had been an advantage, possibly, to both parties to it.

Mr. BRIDGE said that he thought the writing of papers on such a wide subject as photographic art would, probably, always commend itself to two classes of people—viz., secretaries who wanted matter for their meetings, and editors who wanted copy.

Mr. SINCLAIR was fully in accord with the remarks which had fallen from Mr. Bayley. For himself, he admitted that he had learnt more by seeing good pictures than by reading about them. He contended, however, that a photographic Exhibition should be representative of art all round, and not of the art of a clique.

Mr. HAES said that we must largely be guided by the standard of art of the times. He said that many pictures were admitted now to the Royal Academy which would not have been admitted some years ago, and *vice versâ*. No rule could be laid down as to what was good art. There would always be a fashion, and it would vary from time to time.

Mr. GOTZ emphasised the fact that photography is a many-sided subject, and that photographic art as generally understood was only one part, and perhaps a small one at that.

Mr. WELFORD expressed his disappointment—his great disappointment—at the paper. He expected to hear something which would lead to a good discussion, whereas the writer had dealt with the subject in such a manner as to leave the expressions of opinion almost all of one character. He said that the paper was really only a long tirade against H. P. Robinson and the Salon. As regarded the latter, whatever might be the verdict of postperity, it had accomplished much for the photographic art of this country; every one must work in his own way, and, so far as papers on the art side of photography were concerned, it must not be forgotten that, if there had been a flood of articles upon the art side, the photographic world had been deluged with articles upon technique.

Mr. CHILD BAYLEY, in his reply, said that, as the author of the paper, he must be regarded entirely as a fellow-member in a private club. He had neither the desire nor the power to speak as the mouthpiece of the Society of which he was the servant. He could not accept Mr. Welford's criticisms as being pertinent to his paper. He was glad to be supported in his opinion that more could be gained and learned by looking at good photographs than by reading about them.

Mr. Child Bayley was cordially thanked by the meeting for his interesting paper.

Croydon Camera Club.—No more attractive or profitable evening has been spent at the Croydon Camera Club than on Wednesday, May 20, when that talented and distinguished Russian-American, Mr. NAHUM E. LUBOSHEZ, gave a most animated and graphic series of

SMALL TALKS

upon various photographic subjects. Nothing better could be desired than his little lecture, vivacious and pointed, pithy yet clear, on the way to obtain artistic *portraits which are likenesses*. His description of how the lights of a studio should be arranged was so forcibly put that it will be remembered with advantage by all who were present. How wide or long faces may be produced at will by shifting the sitter was humorously descanted upon. Mr. Luboshez was very severe upon the use of reflectors, which the ordinary portrait photographer is fond of employing in order to help out the shadowed side of the face, and, by aid of quickly sketched diagrams, he explained how such a system produced distortion, which at times was exceedingly grotesque; any how, the face is thereby depicted askew, the eyes being at the same time given a horrible squint. It need hardly be said that such defects are usually not noticed by the ordinary individual, because the negative undergoes revision at the hands of the retoucher. Having explained the foregoing *vice* of portraiture, he proceeded to give *ad*vice upon the way to light a sitter in order to ensure a faithful and fully illuminated portrait. This he demonstrated by using the head of the President as an object-lesson, the members quickly catching up the points thus illustrated by Mr. Luboshez. Another main subject touched upon during the evening was that of bromide printing, Mr. Luboshez detailing with considerable fulness why bromide paper is more adapted to the amateur than many other papers. He also explained why he preferred the iron developer to all other ones, and gave his audience much personal experience which they would not else be likely to get. Greatest interest was evoked by the system advocated of toning the ordinary black image brown. The method described appeared simplicity itself. The print, being developed and fixed in the ordinary fashion, is immersed in a bath of hyposulphite of soda, 10 parts; alum, 1 part; water, 80 parts. The dish is then placed over a convenient source of heat, and with the contained print the solution is heated up to 100 c., when the toning will be complete. Besides the advantage gained by turning the black tone into a brown one, Mr. Luboshez claimed that the bromide of silver, being replaced by a sulphide of silver, made the image more permanent; moreover, immersion in the hot bath was calculated to extract destructive impurities which might be contained, not in the gelatine coating, but in the paper itself. At the close of Mr. Luboshez' remarks, which were by unanimous desire extended until nearly eleven o'clock, Mr. HECTOR MACLEAN, F.G.S. (the President of the Club), warmly eulogised both the manner and much of the matter of Mr. Luboshez' lecturette, and asked members to accord him their hearty thanks. This, seconded by Mr. J. T. SANDELL, was carried by a full attendance with much applause. The particulars of three Club competitions were announced:—(1) Enlargement competition; Judge, A. Horsley Hinton; (2) Lantern slides; Judge, John A. Hodges; (3) Negatives and prints. Valuable prizes are offered in the above classes.

Hackney Photographic Society.—May 19, the President (Mr. Thomas Bedding) in the chair.—Mr. J. A. SINCLAIR gave a demonstration of

THE ARTIGUE CARBON PROCESS,

and showed that most beautiful results could be produced thereby. Briefly, the various operations are as follows: The tissue is to be sensitised by immersion for two minutes in a two per cent. solution of potassium bichromate, and then dried away from the light. Expose beneath the negative for about as long as for ordinary carbon tissue. To develop, immerse the print in water at 85° to 90° Fahr., until the image shows faintly; then transfer to cold water to stop the action, float on to a piece of glass, and then develop by gently pouring on a mixture of fine sawdust and water at a temperature of 65° or 70°. The mixture should be of the consistence of thick soup, and should be poured on continuously until the image is entirely up. Immersion for ten minutes in a five per cent. solution of alum, afterwards well washing and drying, completes the process.

Liverpool Amateur Photographic Association.—The fourth excursion of the season took place on Saturday last, when a party of twelve members and friends, under the leadership of Mr. James Parkinson, left at 8 a.m. for Chirk,

and proceeded by the tramway to Castle Mill, which was reached about 10.15. A beautiful day was enjoyed in photographing the charming scenery of the Ceiriog Valley up to the picturesque village of Llansaintffraid Lylyn Ceiriog, and about eighty negatives were obtained. Tea at the Glyn Arms Hotel was followed by a drive back to Chirk, and Liverpool was reached about eight o'clock.

Correspondence.

☛ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

BROMIDE PAPER FOR NEGATIVES.

To the EDITORS.

GENTLEMEN,—As a dealer and an amateur, I heartily endorse "W. R. F.'s" remarks in your issue of the 22nd ult. with this addition, Reduction in weight as well as cost.

I have just placed in my slides six 12 × 10 plates, weighing five and a half pounds, and shall have the pleasure of carting this dead weight of glass about.

What is wanted, and wanted badly, is a sensitised film on paper as a means of taking negatives thereon. You may point out to me that there are films on the market securing that reduction in weight so ardently desired; but, then, look at the price! They are luxuries, not ordinary daily food. Why cannot we have slow films at the price of slow plates, and a sensitive film on paper at half the present prices of plates? I am constantly asked why celluloid films are so expensive, and why we cannot have paper films without this messing stripping business.

Messrs. W. & W. are to be congratulated on their new production, but we are still waiting for a paper film, and the manufacturer who places one on the market will find he has "struck ile."—I am, yours, &c.,

Leigh, May 25, 1896. WILLIAM HAMPSON.

CURIOUS FORM OF HALATION.

To the EDITORS.

GENTLEMEN,—I have lately been in the south of France, taking, as usual, some architectural views, and had pretty good success, however making some mistakes as to exposure, of which I may speak to you later on. The reason of this letter is, however, to speak to you of a novel happening, at least to me, and which may be an accident I cannot as yet explain, or it may be some new kind of X rays; but I am sure never to have seen the same before. With the idea of taking a certain class of views, and so as to avoid halation, I got all my plates backed. This gave me very good results with most of my views, but a few of them showed something quite different from the usual however, a halo also, not from a strong front light, but from dark objects; the strong white light not encroaching on the dark subject, but, returning on itself, collected around the darkest parts. I send you by mail, and untouched, three prints which are enlargements from 4 × 5 negatives made to 8 × 10. On the largest one, a white building, you can see all the smallest branches of the tree, and prints against sky or building have a halo on both sides. Another one shows a halo around the palm-tree, the building being in the shade. The third one, a white building, also shows a halo around the persons in front of it. Can you, or some one, explain this? The smaller proofs show the same halo, but less noticeable.—I am, yours, &c., A. LEVY.

Asnières.

[The prints sent by M. Levy very plainly indicate the curious phenomenon to which he refers.—EDS.]

FLUORESCENCE OF DRY PLATES.

To the EDITORS.

GENTLEMEN,—The letter from Mr. W. P. Walker in your last issue calls attention to a very interesting point in Radiography. I do not think any one prior to Mr. Walker has thought of employing a dry plate as a cryptoscopic screen, but the fluorescent properties of both dry plates and the glass and gelatine employed in their manufacture are well known. Nearly all glass is more or less fluorescent according to its composition, and most important according to the temperature and duration of annealing. Gelatine itself possesses this property in a marked degree, and, curiously enough, the source and method of manufacture of various samples seem to affect it.

Let your correspondent take *any rapid dry plate*, and expose it in contact with a luminous calcium sulphide tablet for, say, half a minute or a minute; on separating them he will observe a marked fluorescence from the plate which lasts visually for some little time. If he sticks a band of paper across the tablet, the phenomenon will be more apparent by contrast.

I have no doubt that Mr. Walker is correct in assuming a very large proportion of the fluorescence to arise from the sensitive film itself. Nevertheless, this phenomenon is not confined to any particular dry plate, but is exhibited more or less by all dry plates, without, so far as I have observed, a single exception. Several batches of Edward's "Cathodal Plates" have exhibited this so strongly as to rival a fluor-spar screen. So far as my observations extend I can support Mr. Walker in the contention that the reduction does not take place from the back of the film. To settle this point, a film which showed this peculiar appearance in the early stage of development was fixed, washed, and dissected, and examination revealed that the reduced silver was fairly equally distributed throughout.

The whole question of the most suitable plates for Radiography is most intimately associated with the property of fluorescence; but hitherto, of a large selection of materials (celluloid, tin ferrotype plate, aluminium, zinc, &c.), glass alone seems to give the finest results.—I am, yours, &c.,

The Grove, Hackney, London, N.E., May 23, 1896. J. B. FINDLAY.

CHLOROPHYLL.

To the EDITORS.

GENTLEMEN,—"Orthochromatic" is wrong in thinking that I ever stated that chlorophyll might be employed successfully "in" a collodion emulsion, or that it would be effective when the plates were dry. The glass plate must be flowed with a collodio-bromide emulsion which contains no free silver; then, when set, flowed two or three times with the alcoholic solution of chlorophyll, and finally immersed in water to precipitate the chlorophyll within the film. The plate must be exposed while wet, as the colour sensitiveness is destroyed by drying. Such plates are not more sensitive than the Cadett spectrum plate, and have the disadvantage that they will not bear such long exposures, because it will not do to let them get dry; otherwise the results are about the same.—I am, yours, &c., F. E. IVES.

24, *Southwick-street, Hyde Park, London, W., May* 22, 1896.

AN ABSCONDING OPERATOR.

To the EDITORS.

GENTLEMEN,—Will you please give a description of a man who is likely to call on photographers for retouching, or else he will use the camera, &c., which I sent him out with on Monday, and which he has not brought back. To-day I have been all round where he was sent, and he has not done any work there. In the morning I shall have a warrant issued for his arrest. The following is a description of him:—

Man, about thirty-eight, dressed in blue-serge suit, hard hat, collar, and cuffs, rather red face, sandy hair and moustache, has Oxford shirt which shows below the collar; will most likely call on photographers for retouching, or else be seen with the following camera:—

Lancaster's half-plate instantograph, without shutter; small spirit level on top. Has two double dark slides, numbered, in black lead on the bottom edge, 1·2 and 3·4. Slides are carried in black cases, which have small ivory tablets on one side for writing on. They are numbered between seven and twelve. Tripod has one stretcher pin loose, and a small split on the inside edge, where one of the stretchers go. Black-velvet focussing cloth, and small black Gladstone bag, with nickel clasps. Has most likely walked into Surrey.

If you can help me in any way to regain apparatus, you will greatly oblige.—I am, yours, &c., A. W. HOLLIDAY,

Photographer and Picture-frame Maker.

Market-street, Alton, May 19, 1896.

THE CARDIFF EXHIBITION.

To the EDITORS.

GENTLEMEN,—Where must the line be placed that separates the amateur from the professional? It has hitherto been understood that *when money is taken for work done* the amateur ceases to be, and the professional area is entered. The Cardiff Exhibition contains a photographic studio ostensibly run by amateurs, but *money is taken there for work done.* Has the line been cut, sir? If not, it has "sagged" awfully, and the "slack" requires hauling in.—I am, yours, &c., A. HORTON.

Central Studio, Caroline-street, Cardiff, May 25, 1896.

ASSISTANTS AND THEIR GRIEVANCES.

To the EDITORS.

GENTLEMEN,—I desire to add my vote of thanks for the excellent leaders on the above subject, published in your issue of May 15, in which you sympathise with their demands; and I am sure all assistants will recognise this, they owe a very signal debt to the Editors of the JOURNAL for exposing the sweating and bullyings which are carried on by those cheap firms. If the letters published in your columns from time to time are from assistants who have suffered from the treatment meted out by the principal of a firm of cheap photographers (of whom I have

had a slight acquaintance), they are by no means "overdrawn." It would be impossible here to detail all the petty acts of tyranny and injustice practised by this firm on their assistants which have come under my notice. Should this firm still refuse to yield to the demands of their assistants for better treatment, the name of the firm should be published. They would then have to face the music, which would be a bad omen for them.

The public who patronise these cheap firms believe the assistants employed by them have comparatively easy work. Short hours, long holidays, good salaries, and in short, by comparison, with many other workers, that they are a class that live in "clover." The truth is that operatives' and assistants' work is in the highest degree exacting and nerve-wearing; that, with exceptions of the comparatively few operators mentioned in your leader with a salary of two or three hundred a year, it is miserably underpaid work. It is the "mere lads" mentioned in "A Retoucher's" letter, who, after a little learning, fancy they are competent operators, &c., who over-stock the labour market, and reduce the rate of pay with regard to the "Polytechnic photographer." It is a well-known fact that one institution turned out large numbers of young men who, after going through a three months' course of printing (fee 10*s.* 6*d.*), rush on the market as printers; meanwhile the benefits offered by a Union are becoming more widely understood and appreciated, and assistants should strain every nerve to form one. It will be a good thing for assistants, but like other good things they are not to be had or kept going without money, and I think a special effort should be made to finance a Union by means of a subscription list, say in the JOURNAL, assistants could send in their loose cash, which they would probably not spend otherwise so well. Failing this, I trust assistants generally, and especially Mr. Randall, will not relax their efforts to promote the establishment of a photographic assistants' branch of the Shop Assistants' Union.

The essential point is that twelve (according to Rule XXXIII. of the Shop Assistants' Union) capable and energetic assistants should be formed to start a branch with, who will, first of all, do the necessary hard work, and who will, in the next place, understand and trust each other. Can photographic workers supply this need? If they can, much may be achieved, and in this, as in most other lines of effort, to be faithful and effective in small things is the best avenue to success to form a Union on the larger scale. It is therefore profoundly to be hoped that operators and photographic workers generally will respond heartily to the opportunity and the generous conditions extended to them by the Shop Assistants' Union.—I am, yours, &c.,

London, May 25, 1896. FRANK BRISLEY.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

John Patrick, 52, Coniston-road, Edinburgh.—*Photograph of Birth-room of Thomas Carlyle, Arched House, Ecclefechan, N.B.; Photograph of Thomas Carlyle's Study, Craigenputtoch, Dumfries-shire, N.B.*

SALARY.—"BOB." Your query was answered last week. Do you not read the JOURNAL?

COMPOSITION.—E. G. RICHARDSON. We do not know the composition of the material mentioned. We imagine it is a trade secret.

EMPLOYMENT IN DRY FACTORY.—L. COOMBE. Sorry we are unable to help you. We know of nobody who is about to start in the manufacture of dry plates.

LOAN OF APPARATUS.—W. B. W. We believe that Messrs. Sands & Hunter, and Merley & Cooper let photographic apparatus out on hire. We are not aware upon what terms.

C. S.—The article is clear enough, if it be followed. Any good optician, who makes microscopes, will construct the apparatus for you—Messrs. Ross, Dallmeyer, Perken, Son, & Rayment, or Wray, for example.

PATENT TITLE.—TRADE writes: "If I take out a provisional patent, cost 1*l.*, and do not complete it, can I mark the article 'Patent' for trade purposes?"—Certainly not. If you did so, you would render yourself liable to a heavy penalty.

PAPER FOR WOODBURYTYPE.—T. BALL. We are not sure that paper, ready for use, for Woodburytype printing is to be purchased in this country; we think not. Possibly, however, Waterlow & Sons may supply it; if not, you can obtain it from Liesegang, Düsseldorf.

PARAFFIN *versus* GAS.—A. MACINTYRE. A paraffin oil stove for heating is far preferable to a gas stove in a room where silver paper and carbon tissue is dried. The fumes from the former, though unpleasant, are far less injurious than are those from the latter, though there is no smell with them. If the oil stove is kept clean and the wick in trim, there will be little or no smell.

BRONZE-EDGED MOUNTS.—SIMON. The chemist has deceived you; the edges of the mounts are not gold at all, but ordinary bronze. This you can prove for yourself by touching the "gilt" with a weak solution of nitrate of silver. Return the mounts, and demand your money back. Any respectable photographic dealer would have supplied gold-edged mounts for the price you paid.

DAMAGED LENS.—C. CHARLES. Apparently nothing worse has happened than that the two glasses have become uncemented through the balsam giving way. We do not recommend novices to attempt recementing lenses, though it is a simple operation if the glasses are not burnished in thin cells, which most lenses of the rectilinear type are. Send the instrument to any maker of photographic lenses, and he will do the work for a very small sum.

COPYRIGHT.—J. H. JONES says: "In your issue of July 10, 1891, in the column headed 'Answers to Correspondents,' you will find a notice that I registered two photographs of model of house in which Nelson was born. Will you please inform me whether the copyright has run out; and, if not, what steps I must take to renew the same?"—The copyright has not run out; it will last for your life and seven years after your death, counting from date of registration.

LENS FOR PORTRAITURE.—W. S. B. writes: "Would you kindly say what would be the best lens to use to take a full-length cabinet in a studio that will only allow twelve feet from sitter to lens?"—No lens that has yet been constructed will take a full-length portrait in so short a distance with good perspective. The question simply resolves itself into one of covering power rather than ferm of lens. A lens of about seven and a-half inches equivalent focus will be necessary, and will have to be stopped down until sufficient covering is obtained. Possibly a lens of the "extra rapid" type will be the best.

STEAMING SHOW-CASE.—SPECIMEN writes: "I am much troubled with steam on the inside of my show-cases. As soon as the sun gets on them the glass is covered with dew, and the pictures cannot be seen. Is there any remedy?"—There are two. One is to have plenty of ventilation in the case, so that the moisture can escape freely; the other is to thoroughly dry the mounts, pictures, and backboards, and then hermetically seal up the cases so that no moisture can gain access. In this case the backboards should be thickly painted so that they are impervious. The latter is the better plan, as then the pictures are the better preserved from fading.

VARNISH TO BE APPLIED COLD.—W. REED says: "The other day I watched an itinerant photographer at work, taking glass positives. After the portrait was taken, he recommended the customer to have the portrait varnished, to preserve it—additional charge, 3*d.* I noticed that the varnish was applied to the cold plate, yet it dried quite glossy. Can you tell me what varnish it was, as it ought to prove very useful for negatives?"—Probably the varnish was simply dammar resin dissolved in benzole. That is what is generally used for glass positives. It is not, however, a very durable varnish for negatives, as it will not bear rough usage. A very hard varnish, to be applied cold, can be made by dissolving amber in chloroform, but it is necessarily expensive.

YELLOW PRINTS.—E. PARKS asks: "What is the cause of the yellowing of the enclosed prints? it made its appearance while prints were in washing under running water between aluming and toning; also the cause of the metallic stain? I have been using P.O.P. for about three years, and never had it appear before. I have lost about eighty prints out of one hundred and fifty, is there any way of taking out yellowness? I have thought that it has been caused by the silver and alum not being properly washed out. When washing my prints after fixing, I change them from one dish to another for two hours, each change taking about ten minutes; is the hypo likely to be washed out in that time?"—The stains are due to faulty manipulation—in all probability from the prints being washed in a dish, or water, contaminated with hyposulphite of soda. There is no way of removing the stains. The washing after fixing will be sufficient if plenty of water be used.

SPOTTY PRINT.—L. B. asks: "Can you give me any information as to the development of the small white spots on the enclosed print? There are several of my photographs, in the same album from which this was taken, gone in the same way, but most of the others are all right. I have a print myself from the same negative as the enclosed which is in perfect condition, and was printed at the same time. It cannot be from any negligence on my part, I think, as I am most particular in fixing and washing. The album is a very common one; and I use gelatine as a mountant. I might also add that the photograph will not be above twelve months old."—There are so many causes that will conduce to spots like those on the print sent. The mere fact that the one sent was kept in common album and became spotty, and another that was not so kept did not, will not, we think, account for the spots. If the two prints were identical as regards mounts and mountant, the cause must be sought for in the manipulations.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1883. Vol. XLIII.—JUNE 5, 1896.

Contents.

EX CATHEDRÂ.

Messrs. Cadett & Neall are issuing with their price-list of dry plates some interesting particulars relating to their recently introduced "Spectrum" plate. They enclose a copy of the colour chart which is given with Cassell's *Technical Educator*, as well as a reproduction in half-tone from a negative on a "Spectrum" plate of the said chart. No more effective method could be chosen for demonstrating at a glance the power possessed by a plate of more or less correctly translating colour values into monochrome.

* * *

As regards the manipulation of the "Spectrum" plates, Messrs. Cadett & Neall say: "Where perfectly orthochromatic results are desired, a light yellow screen must be used. With the following light filter all visible colours are rendered correctly according to their luminosities. The filter should be made with a cell one-eighth of an inch thick internally, containing a solution of pure chromate of potash, one part of the salt to 250 of distilled water, made slightly alkaline with pure caustic potash or carbonate of potash."

The entire manipulation of the plates, Messrs. Cadett & Neall state, should be carried out in total darkness until the negative is nearly finished in development, when a moderate amount of the dark-room light may be cautiously used. The "Spectrum" plate is stated to be very slow, but we understand that Mr. Cadett will shortly have ready a plate of much greater rapidity, with the same colour-rendering properties. In passing we rank it as a tribute to the enthusiasm of the manufacturers that the plates appear to have to be prepared under as great disadvantages of illumination as are necessary for their development.

* * *

The Speaight Studio is the name given to a new studio which Messrs. Speaight have just opened at No. 178, Regent-street—premises that were, we believe, formerly in the occupation of Messrs. Lock & Whitfield. Much skill and taste have been expended in the decoration and adaptation of the various suites of rooms, which comprise the usual reception, waiting, and dressing rooms, studio, dark rooms, and various other rooms devoted to the actual production of the photographs. The "colour scheme" adopted creates an impression of elegance upon the mind of the visitor, a light tint pervading the decorations and furniture. The studio struck us as being extremely well appointed, the accessories are in good taste, and the backgrounds judiciously chosen to give natural effects. Messrs. Speaight, whose work is of good class, have a moderate scale of charges, and we hope will receive a profitable share of the public patronage.

* * *

Replying to Mr. Hill, who, in our correspondence columns, a fortnight ago, expressed some anxiety to know when M. Jarchy, photographer, of Union-road, Rotherhithe, would hold the baby show he expressed, so long ago as last September, an intention of holding, we have received from M. Jarchy a letter which, we regret, is couched in terms that render its publication inadvisable. To say the least of it, M. Jarchy is very frank towards his interrogator. However, he has been kind enough to state when the baby show will be held. Thus:—"No. 1. A Baby Show for the Competition of Beauty, Health, and Weight, will be held as soon as M. Jarchy can secure 1000 children to select from."

* * *

"One thousand children to select from" is, if we may quote one of the favourite locutions of the day, a large order; still,

with perseverance and a little inducement to the mothers of the small people to come forward, we see no reason why M. Jarchy should not succeed in his object. We wish him a speedy realisation of it, and trust to be favoured with an invitation to the Exhibition—when it is ready to be opened.

* * *

THE old grievance of the war of prices crops up again in the letter of a country correspondent. "What can be done," he asks, "by the Royal Photographic Society when a member treats his profession in this manner?" He refers to the bold advertisement of a firm of photographers, in the same town as himself, who announce that during the month of June they will take first-class photographs at half price on certain days. This is a matter in which the Royal Photographic Society, cannot interest itself for the simple reason that the regulation of photographers' charges does not come within its scope. The half prices in this instance charged are 10*s.* 6*d.* per dozen for cabinets, and 5*s.* 6*d.* per dozen for *cartes;* and the prices are certainly low, but we could point to numbers of cases in which they are lower. As to the main question involved, experience shows that the unreasonable lowering of prices ultimately retards, rather than advances, business, so that the wisdom of such competitive methods is not obvious.

* * *

MR. W. BROWN, 9, Gilmour-street, Paisley, writes with reference to our note in a recent number of the JOURNAL as to a skin complaint being caused by hypo: I may say that I have suffered from the same for some years, and blame the pyro and ammonia as the original cause, although hypo will irritate the complaint; indeed, long working in cold water will revive it after once started. To prevent it in the first instance, I think it advisable to lift plates from the solutions with a thin, flat crochet pin; I have tried many remedies, but the following is the only one which has been effectual with me, and for which I am indebted to a photographic chemist. Before using, wash the hands with Castile soap or coal-tar soap. Liniment of iodine, say half ounce, one or two applications with brush or cork will dry up the disease. To relieve the irritation and to prevent a return of the complaint, I use always after developing, and when troublesome, the following wash:—

Carbolic acid	1	drachm.
Wright's coal-tar solution	½	ounce.
Glycerine	3	drachms.
Water up to	12	ounces.

EXPERIMENTS UPON HYPO RESIDUES.

WE return again to a topic before dealt with in this column, in the hope that a set of experiments we have made will throw further light on the practical aspects of the subject, and lead to a proper appreciation of a correct mode of treatment in which all the metal may be recovered. It is one of the most remarkable facts in connexion with photography on a large scale that, notwithstanding all we and others have written and said on the subject, there still remains a large majority of workers who never attempt to recover the silver from waste hypo fixing solutions, and, of those who do attempt it, a large proportion go about the operation in the wrong way. In proof of the former assertion, we may say we have been informed, by one of the principals of what is, perhaps, the largest portrait publishing firm in the country, that they never, under any circumstances, attempt to recover the silver from waste hypo solutions. We were almost incredulous, till we were assured again that all the waste hypo went down the sink. It was not for us, of course, to ask so close a question as to the amount of silver used; we think we should not be over-estimating if we said that a hundred pounds sterling would not cover the value of the metal thus wasted.

Let us repeat what we have said before many times. Taking ordinary home-sensitised albumenised paper, the silver recovered from the washings of the prints will not be equal in value to that obtainable from the fixing solutions. Taking ready-sensitised albumenised paper, the washings are not one-fifth the value. Taking P. O. P. or collodio-chloride papers, there is still less precious metal in the washing waters. With regard to the latter there is apt to be some misconception, for there is usually a considerable milkiness produced in the water the prints are placed in to soak; but this is not silver chloride, but baryta white, used in the manufacture of the paper.

Turning now to a consideration of how to obtain the silver from the hypo, there are three leading plans in vogue, where the hypo is treated at all. They are, firstly, the addition of strong acid; secondly, the suspending of strips of metal, such as zinc; thirdly, the addition of solution of liver of sulphur.

We have been surprised to learn how often the plan is adopted of adding strong acid to the hypo, and our hearers are usually surprised, and generally incredulous, when we inform them their method is useless as usually worked. We are told in reply that, so far from the silver not being thrown down, there is a large amount of precipitate produced. The answer to this is, that the same precipitate would be seen if perfectly fresh, unused hypo solution were experimented with. The precipitate obtained in the usual manner is neither more nor less than sulphur, with possibly a slight, very slight, percentage of silver and some gold. So persistent is the idea of the value of this precipitate from hypo, that we determined to make actual trial, and give our readers the benefit of the experiments.

Having in our possession several gallons of old fixing baths, we started by adding pure hydrochloric acid, sp. gr. 1·42, in a measured quantity. Though, in actual practice, commercial acid would be used, the results with pure acid would be the same, and there would be no fear of the presence of the iron usually found in the crude acid masking the simple reactions. We used what we thought would be a maximum quantity in practice, five fluid ounces to a gallon. In a very short time the solution became cloudy, and shortly afterwards a dense, dirty, yellow precipitate was visible. Leaving this to settle, we, at the expiration of twelve hours, drew off a portion of the supernatant fluid and filtered it. Upon testing it, after neutralisation, with sulphydric acid, we obtained a dense precipitate of sulphide of silver, and when testing it in a diluted form the indications showed little, if any, diminution in the amount of silver originally present. We then increased the amount added to half a pint of acid to the gallon, without any alterations in result of the experiment. Next we added acid at the rate of fifteen ounces to a gallon, a quantity that is not likely ever to be used in practice. Still the silver remained in solution, and the precipitate was more difficult to deal with, as a portion floated upon the surface of the solution. Finally we added a pint of acid to the gallon: result, sulphur, very dirty-looking, thrown down; almost all the silver left in solution.

We had by this time very little hypo solution left, so we

added the hydrochloric acid to a small quantity, almost an equal measure of each, acid and hypo; then, and only then, did we find, after a day's rest, that the supernatant fluid contained no silver; all the hypo was decomposed, in fact, and there was nothing to keep the silver dissolved. We obtained a large mass of precipitated sulphur, with a small quantity of silver mixed with it.

It is, however, quite plain that such a proportion as this is never used in practice, and would indeed be absurd. Hence we can only repeat what we have said before, and now more strongly in the light of these actual experiments. It is useless to attempt to recover silver from hypo by means of the addition of strong acid. We have so recently written upon the use of liver of sulphur, that we need not again refer to it, except to say that, though offensive in smell for a brief time, its action is as perfect as that of the well-known kitchen salt for precipitating the chloride from first washings of albumenised paper prints.

ORDINARY DRY PLATES FOR PHOTO-MECHANICAL WORK.—II.

We do not intend in this place to indicate the remedies for this state of affairs,* chiefly because, in using plates of the highest rapidity, we do not think any remedy possible under the most favourable circumstances. We mention the conditions simply in order to emphasise the fact that, while the collodion plates were workable, the only moderately rapid gelatine ones were not. The internally reflected light, while not powerful enough to seriously affect the collodion film, which is notoriously insensitive to weak radiations, was more than sufficiently so to destroy any chance of success with gelatine, though far removed from the highest stage of sensitiveness.

After this digression we will proceed to describe the manner in which we succeeded in perfectly adapting these gelatine plates to our purpose, even without any material alteration of the other conditions beyond masking the margin of the subject, which still cast a considerable amount of reflected light into the camera. The specially prepared photo-mechanical plates, as is well known, are much slower than the slowest in ordinary use, and we consequently set about reducing the sensitiveness of those in use.

The first attempt made consisted in immersing the gelatine plate in a solution containing sixty grains of bichromate of potash and thirty grains of bromide of potassium in ten ounces of water for three minutes, afterwards washing thoroughly, and, after draining, exposing while still wet. This, we had anticipated, would have materially reduced the sensitiveness of the film, but the result was in no way different to what we had already obtained, and, on trying a plate so treated side by side with another not treated, beyond a scarcely perceptible increase of clearness in the shadows, there was no difference. The same treatment, in fact, applied to a plate of greater rapidity, which was liable to a slight veiling in development, actually had the effect of increasing its rapidity, for by removing the tendency to fog without directly lowering its sensitiveness, as we should have expected, it permitted the development to be pushed further, with the result indicated.

Although this treatment failed in reducing the rapidity, as we had expected, it provides a means by which deteriorated or foggy plates can be brought into a utilisable condition, and, as such, it will be found most useful; and, where such plates are to be eventually lowered in sensitiveness, it should always be applied as a preliminary treatment, as the first essential is an absolutely clean film.

The next attempts were made to lower the sensitiveness by impregnating the film with a more or less dilute solution of bromide and iodide of potassium alone and in combination and conjunction also with gallic acid, which is known to have a very powerful slowing action; but whether it is a slowing action on the plate itself, or only a retardation of development, has not been satisfactorily decided. This gave a better result, but still not what we required, even when the plate was treated with a cold saturated solution of gallic acid, with two grains of bromide and half a grain of iodide of potassium to the ounce. The plates were allowed to soak in this solution for two minutes, drained, and exposed without washing, and, though considerably "slowed," were not placed beyond the influence of reflected light.

We then remembered an experience of several years back with a batch of commercial plates, which were subsequently found to contain traces of bichromate of potash used in their preparation and not completely washed out. These, when applied to landscape purposes, gave the most perfectly graded and most brilliant images it is possible to imagine, and with an ordinary exposure; but, beautiful as the image appeared before fixing, it disappeared almost completely in the hypo, only the high lights remaining with any strength; indeed, it was only the sky or white objects in sunshine that retained any density sufficient for printing purposes. Increase of exposure had not the least effect on the shadows and half-tones, though, by such treatment, the highest lights increased in density, while the half-tones almost disappeared, and the shadows became absolutely clear glass in fixing.

This suggested the lines upon which to proceed in adapting our dry plates to the requirements of line and aud half-tone work, and, after a few trials, we succeeded in obtaining results quite equal to any obtainable with the specially prepared photo-mechanical plates. The precise quantity of bichromate to employ must be very small, and it will vary with different plates; some will bear or will require more than others. It is applied by simply soaking the plate for a given time in a solution of known strength, and draining without washing. Half a grain of bichromate to the ounce we have found a suitable average strength. If the solution will not drain evenly off the plate, it must be blotted off with a pad of linen or cambric, or unequal action will result. We hope to report further of this process after more extended trials.

* See page 338.

The Best Form of Crookes' Tube for Röntgen Work.—Just as in the earliest days of photography the form of lens to be used was the least important consideration, so, with Röntgen photography, the marvellous nature of the results almost overwhelmed every other thought but that of photographing through opaque objects; but, for some time past, it has been seen that the actual shape of the tube has a most important bearing, first, upon the rapidity of impression; and, secondly, upon the sharpness of outline in the object delineated. For some time past the form devised by Mr. Jackson has been looked upon as the best, and it is stated that this form of so-called "focus tube" is now made use of by Röntgen himself. A large number of investigations have been made upon the subject, both theoretically and practically, with the result that the Jackson form, or one founded on it, proves the best.

A very neat form has been devised by Messrs. Brady & Martin, consisting of a narrow tube in which the concave cathode faces the

usual platinum plate, but the latter is immediately attached to the anode.

New Form of Tube.—Writing in *La Nature*, M. Gaston Tissandier says that for a tube to give the maximum sharpness three requirements have to be fulfilled: Firstly, the cathode (supposed to be the plane) should be of restricted dimensions: secondly, the bundle of rays from the cathode should strike the walls of the tube at a short distance from the cathode: thirdly, the cathode ought to be sensibly of the same diameter as the tube itself, and so arranged as to form a partition dividing the tube into two compartments. Following upon these considerations, it will be thought that sharp photographs will be obtained with a narrow cylindrical tube containing a cathode of almost the same diameter as the tube, and placed sufficiently deep down the tube as not to be separated by any great distance from the anode or anti-cathodic wall. This form of tube has been employed in an experimental trial and found to give very sharp images. In last week's *La Nature* two illustrations are given, one with the ordinary Crookes' tube and the other with the new form just indicated. The first is very indistinct in outline, while the latter is marvellously sharp and clear. The tube was placed fifteen centimetres (six inches) from the object, and when one minute's exposure was given with a six-centimetre (about two and a half inches) spark coil, a sharp and fairly good image was given Even in one minute a negative was obtained, feeble but sharp.

Röntgen Rays at the National Academy of Science.—Washington Meeting.—Naturally great prominence was given to the New Photography at this meeting, and Professor Rowland's contribution was remarkably interesting and full of suggestiveness. He pointed out that the greatest development of the rays took place when the cathode discharge fell upon the anode, so that a curved-surface cathode, the reflections or molecular bombardments from which fell upon a reflecting surface, preferably of platinum, gave the best results. At the same meeting, however, MM. Michelson & Stratton expressed their views to the effect that the Röntgen rays were similar to the Lenard rays, and that they radiate in all directions from the surface first encountered, and that they do not start from the anode.

Professor Rowland obtained excellent results with a perfect vacuum tube, in which the electrodes were placed within one millimetre from each other. The starting point of the rays is there less than the one-thousandth part of an inch in diameter, and gave a shadow of remarkable sharpness.

Failures with Tubes.—Mr. Gifford writes to *Nature*, detailing certain failures and their causes. At one of his demonstrations two of his tubes that had acted perfectly shortly before entirely failed to act at the lecture. He thought it possible they had been over-worked—it is well known that the "fatigue" arrests their action; but he eventually traced the cause to the fact that the platinum reflector, owing to the unusual length of spark, had become red hot, at which stage they appear to cease to be able to give off the Röntgen rays.

It has been found that, after a tube has been used some time, and ceased to act quickly through the walls of the tube excluding a portion of the rarified contents, it may be brought back to its former condition by gently heating in a Bunsen burner flame, which causes the gas to be rediscarged.

The Whole of the Spectrum Photographed on one Plate.—Professor Liveing exhibited at the Philosophical Society at Cambridge photographs of a variety of spectra in which all the spectrum between lengths 550 and 214 was taken at one operation on a single plate, or, rather, sheet of celluloid. He used a concave grating of ten and a half feet radius, with the slit in the centre of curvature, the slide which held the film forming part of a cylinder five and a half feet radius: the result was that the whole of the spectrum was sharp at one time on the film.

The Explosiveness of Celluloid.—Many stories, chiefly of the *ben trovato* type, have been told with regard to the alleged explosiveness of celluloid, and we recollect with what awe the statements were received by the "lay," or non-scientific, public of billiard balls and artificial teeth, composed of that material, having unexpectedly exploded when used with rather too much vigour. Last week, the *canard* crops up again in a quasi-scientific contemporary, where the story is told of the "explosion" of so harmless an article as a celluloid collar. The driver of a traction engine, we are told, was the victim; he was driving his machine when a spark caught his collar, which "exploded with a loud report," and, seizing the collar to tear it off, he was severely burnt about the hands and face. The account does not explain how it was that, if the collar "exploded," it remained to be torn off; that might have been the cause if it had merely "taken fire," but the "loud report" establishes the case, for the purposes of the story at least, as a genuine explosion.

After many years' experience with celluloid in a great variety of forms, we have yet to meet with an instance of its explosiveness under ordinary, or indeed any, circumstances. That the basis of the composition known as celluloid or xylonite is gun-cotton is quite true, as well as sufficient to establish its dangerous character in the minds of the ignorant and unthinking, but those who are best acquainted with it will be aware how utterly absurd such stories are. That in some of its forms, more especially when on thin sheets or films, it is inflammable goes without saying, but in this respect it is not more dangerous than ordinary paper. It is true that, if a quantity of it got "well alight," to use a fire-brigade expression, it would require prompt and energetic measures to extinguish it; but we think the chances of accidental firing would be less with celluloid than with paper. Let any one who doubts this try the experiment of trying to ignite a celluloid negative and a piece of ordinary paper, and see which takes fire the easier. In its more solid forms, as in thick sheets or slabs, brush handles, combs, and the innumerable fancy articles for which it is now used, it is extremely difficult to get it to burn at all unless thrown into a hot fire. The gun-cotton from which it is made is of the lowest grade of explosibility, and mixed, as the manufactured article is, with a variety of other substances, this quality is scarcely likely to be increased. Those, therefore, who make celluloid negatives need not be alarmed for their safety.

This reminds us of an instance which shows how readily the non-scientific but "clever" mind works in and to its own interests. Some years ago, in the pre-gelatine days, we were discussing with the representative of one of the largest fire insurance offices the question of photographers' risks, and asked why it was that the companies almost unanimously refused to insure negatives at any price. The reply at once amused and startled us, for it was to the effect that photographic negatives formed one of the most hazardous of risks, owing to the glass being coated with a highly explosive compound of gun-cotton! Truly a little knowledge is a dangerous thing.

THE CAUSE OF THE RELIEF IN GELATINE NEGATIVES.

The relief which occurs in a finished negative, produced under certain conditions, must have attracted the attention of a beginner before he has finished the development of his first dozen plates, and yet no explanation of this phenomenon has been given beyond ascribing it to the tanning action of pyro on gelatine, though it is obvious that, if this is the case, the whole of the gelatine should be made equally non-absorbent of water, and we should have no solution of the gelatine taking place such as occurs sometimes when negatives are being developed in a tropical country. Pyro pure and simple has no tanning action, if by tanning is meant rendering the gelatine less absorbent of water, and causing it to go into solution

at a higher temperature than it would if soaked in pure water and warmed; pyro, *per se*, has, on the contrary, a softening action, and if gelatine be soaked in a strong solution of pyro (without addition of any other body), as soon as it is thoroughly saturated with the solution, the shreds of gelatine will gradually coalesce into one soft mass.

That pyro has no tanning action on gelatine we proved by closing one end of a glass tube about half inch in diameter, placing some gelatine in it, and some solid pyro; the open end was then drawn out, and, after filling the tube as full as possible with water, it was sealed. When the sealed end of the tube had become cold, the contents were heated, and the gelatine was found to dissolve at the same temperature, or even a lower one, than did the same sample of gelatine when simply soaked in water, and then the melting point determined.

Gelatine in this condition will not "set" at a much lower temperature than it would if dissolved in pure water: the temperature of the blood is sufficient to cause such a mixture to become fluid enough to allow a bubble of air to pass from one end of the tube to the other when it is placed in a vertical position.

Another tube containing gelatine and a solution of pyro was prepared and allowed to remain at the temperature of the air for some time; it was found that the shreds of gelatine gradually coalesced, and, on placing the tube in a vertical position, the mass flowed from one end to the other like a viscous liquid.

These two experiments, we think, proved conclusively that gelatine is not tanned or rendered insoluble by the action of pyro pure and simple.

Before making these experiments, we soaked some gelatine in a solution of pyro, and tested the temperature at which it went into solution: we found this temperature a little lower than was observed when a sample of the same gelatine was soaked in pure water and its solution point tested. On the following day, a few shreds of the gelatine which had been left in the beaker containing the pyro solution, which was now very dark in colour, were tested, and found to be absolutely insoluble even in boiling water; the tanning action is not due, therefore, to pure pyro, but to the products of its oxidation.

When once gelatine has been stained by the oxidised pyro, we have found it impossible to remove the colour, the gelatine and certain products of oxidation have so powerfully combined that only decomposition of the gelatine will cause it and the colour to go into solution.

In our recent paper on *The Solubility of Silver in Hyposulphite of Soda*, we referred to the fact that, after all the silver had been removed both from developed paper and plates, there remained a brownish-yellow stain, having the same gradation as the original; this stain is due to the combination of the oxidised developer and the gelatine, and this stain is unaffected by the hyposulphite of soda. When a line subject is reproduced either on paper or on a plate, and developed with pyro, the oxidised developer renders the gelatine insoluble where the light has acted on the film, as there the oxidation of the pyro is greatest and thus the gelatine is tanned locally, these particular portions of the film thus absorbing less water and swelling less than the unexposed parts, in which the gelatine not being altered absorbs the maximum amount of water it is capable of doing, and is thus swollen to a greater degree than the tanned portions; and it is for this reason that we obtain relief in gelatine negatives.

About fourteen years ago Mr. Warnerke worked out a process in which the film, after development, was in part dissolved by means of warm water, those portions which correspond to the shadows being soluble in warm water, the portions that correspond to the high lights and half-tones being more or less insoluble. Mr. Warnerke simply gave the results of his investigations, but, as far as we can remember, advanced no theory in explanation of his observations.

It is also due to this same tanning action that gelatine negatives which have been dried swell but little when soaked in water, the oxidised pyro having tanned the gelatine to such an extent as to render it non-absorbent of water; it is thus difficult to dissolve the gelatine from old negatives, as, from the time the plate leaves the developer till it is thoroughly fixed, the pyro which the gelatine contains still continues to absorb oxygen, and, combining with the surface gelatine, renders it insoluble in water even when hot.

In order to ascertain whether the tanning action is due to only partially oxidised pyro, or to pyro which has absorbed as much oxygen as it possibly can by free exposure to the atmosphere, the following experiment was tried. A strong solution of pyro containing carbonate of soda was placed in a tube and air bubbled through it for sixteen hours; at the end of this time, the solution, which had become of a dark brown colour and syrupy consistence, was transferred to a beaker and some shreds of Nelson's No. 1 Photographic gelatine soaked in it for twenty minutes: the gelatine was then washed for about an hour in running water, and transferred to a test tube containing water which was gradually raised to the boiling point, but the gelatine refused to go into solution. On the addition of a few drops of nitric acid and further boiling, the gelatine dissolved to a very deep-coloured solution. We find that, of all the different reagents we have tried, a dilute solution of hydrochloric acid has the greatest power of lowering the temperature at which the pyro-tanned gelatine goes into solution, though, as is well known, a solution of potassium bichromate containing sulphuric acid dissolves it in the cold.

We have noticed, when using some of the more recently introduced developing agents, that in some cases no relief was visible in the negative after fixing and washing, though in other cases it was very marked.

In order to test the tanning properties of the modern developers, strips of gelatine (Heinrich's) were soaked in solutions of the following, rendered alkaline by the addition of a small quantity of sodium carbonate, metol, di-amido-phenol, glycin, eikonogen, hydroquinone, rodinal, and amidol, the strips of gelatine were allowed to soak in the different developers until they had absorbed as much of the solution as possible, which took about ten minutes. The strips thus saturated were attached by one end to a sheet of paper and exposed to the air till thoroughly dry: during the process of drying the gelatine strips soaked in the solutions of amidol, metol, eikonogen, di-amido-phenol, and hydroquinone, became dark brown in colour, the intensity of the stain being in the order above mentioned, the gelatine soaked in the glycin and rodinal solutions being unchanged in colour, though the oxidation was allowed to continue for two months.

Small portions of these gelatine strips were soaked in water for about twenty minutes, and at the end of this time they were placed in test tubes half filled with cold water, a thermometer was then inserted and the water gently warmed, the temperatures at which the different pieces of gelatine went into solution being noted; the following results were obtained:—

Developer.	Temperature of Solution.	Remarks.
Original gelatine	45° C.	
Metol	62° C.	Does not dissolve like ordinary gelatine, but breaks into pieces at about 50° C.
Glycin	45° C.	
Di-amido-phenol	80° C.	
Rodinal	45° C.	
Eikonogen	100° C.	Dissolves slightly on boiling.
Hydroquinone	Insoluble.	Hardly softened.
Pyrogallic acid	"	"
Amidol	"	Becomes soft and slimy, but refuses to dissolve.

On examining the above table, we notice that the gelatine treated with pyrogallol, eikonogen, hydroquinone, and amidol, does not dissolve even at the boiling point of water: that treated with metol and di-amido-phenol goes into solution at a lower temperature, whilst the gelatine treated with glycin and rodinal, has not had its melting point altered. From this we might infer that the first-mentioned developers would produce the maximum amount of relief, the second less, and the last none at all; in practice we find that glycin does not give any relief, and most probably rodinal would behave in a similar manner, whilst pyro gives great relief.

We might still further infer that the oxidation products of glycin and rodinal either have no tanning action and are colourless, or that glycin and rodinal do not oxidise when exposed to air even in conjunction with an alkali, and, in order to test this point experimentally, a few grains of glycin were dissolved in water and oxidised by the

addition of a little bromine, then the solution boiled to drive off the excess of the oxidising agent; this produced a slight brown colouration, which, when we had neutralised the free acid produced by means of sodium carbonate, became dark brown in colour, and on soaking some gelatine in this for a few minutes, then washing, and testing the melting point, we found that even at the temperature of boiling water it was quite insoluble. On treating rodinal in the same manner, a similar action was found to have taken place, the gelatine was tanned and rendered insoluble in boiling water. These results show that glycin and rodinal are not oxidised even when freely exposed to air, but by submitting them to the action of such a powerful oxidising agent as bromine, an operation which takes place in the development of a plate, a coloured oxidation product is obtained, which has the power of tanning gelatine, and we would therefore expect to obtain a "relief image" when developing with rodinal or glycin.

It must, however, be remembered that all the modern developers are associated with from five to twenty times their weight of sodium sulphite, when employed as developing agents, the developer merely serving as a carrier of oxygen to the sulphite of soda, the action most probably taking place as follows:—

X	+	2 Ag Br	+	H_2O	=	Xo	+	2 Ag	+	2 HBr
developer		silver bromide		water		oxidised developer		silver		hydrobromic acid

and

Xo	+	Na_2So_3	=	Na_2So_4	+	X
oxidised developer		sodium sulphite		sodium sulphate		developer

This will explain why some of these developers can be used to develop a number of plates, and also why, when these developers are used with a large excess of sodium sulphite, no tanning action of the gelatine takes place, and therefore no relief image is obtained; it will be found that, if a plate be developed with pyro, associated with a large excess of sodium sulphite, no relief image will be obtained, or, if it does occur, it is very much less pronounced than when the sulphite is omitted.

The colour of the tanned gelatine is of a very non-actinic nature and must have great influence on the printing qualities of a negative, and we thus see why a pyro-ammonia developed negative, though apparently very weak and lacking in silver density in the high lights, yields such plucky prints, as, where most silver is reduced, there also the maximum amount of tanning and colouration of the gelatine takes place. Visually negatives produced by the modern developers (with plenty of sulphite) are much denser, but as printers they are often very disappointing, in consequence of the opacity depending entirely on reduced silver; if, however, only a small quantity of sodium sulphite be associated with hydroquinone, eikonogen &c. slightly brown-stained images are obtained with better printing qualities.

When certain of the organic developers are used for the development of plates whose opacities are to be determined on the Hurter & Driffield system, considerable error might be introduced if the reducing agent be not associated with a sufficient quantity of sulphite of soda to prevent the staining of the gelatine.

Any one can easily prove for himself that the image in the gelatine of a pyro-developed plate is not due entirely to silver by placing the plate in a solution of ferrous sulphate; the colour of the image is changed, due to the conbination of the iron and the oxidised pyro in the gelatine. In this way negatives, as is known, can be sometimes slightly improved in printing quality.

DIGRESSIONS.

VI.—Is it Good Enough?

This is a question, not without a suspicion of slang, we often ask ourselves, and the value depends upon the seriousness with which we take our work, and the standard we set up by which it may be judged.

The standard is everything. What do we want to be or do? Shall we work or play? Shall our aspirations lead us to the Salon, or is all that we care for to carry a hired Kodak, and our greatest merit be to wait patiently for the finished prints? These two statea are as wide as the poles asunder, and the photographer can get hot and cold many times between them.

It is said that the cleverest thing to achieve in any art is to find when success is reached.

I remember the frontispiece of an old *Preceptor* of the last century —I used to look upon this as one of the wisest books—which represented Minerva leading a child up a terribly long flight of steps to the Temple of Fame, where there was a young woman blowing a trumpet in anticipation. He appeared to be an intelligent lad, but not altogether happy; but then he had not climbed very far. In the foreground was a group of children playing in a puddle. "Pleased with a rattle, tickled with a straw," it was good enough for them. As Mr. Slawney would say, this was not altogether untypical.

Eighty out of every hundred, probably, who use photography do not care to succeed beyond a certain point, and it does not come within their scope to have any ambition to succeed. It is not every athlete who wants to get from Marathon to Athens in the shortest time, so why should they try? all that I ask for is that those who really are in earnest should be very earnest indeed. As I have hinted, one of the chief difficulties in the arts seems to be to know when the work is finished. Much depends on what we understand by the word "finished." Any sense of laboured effort has a bad effect on the beholder, except those who admire the lesser virtues, patience and ingenuity and care, which are by no means the essence of art. Indeed, if I were asked what I most admired in the technique of a picture, apart from the subject, I think I should say, *a spontaneous effect based on intention.* I have no sympathy with flukes and happy chances, if they are too obtrusive. A very usual criticism on a picture is, "How beautifully it is finished!" when probably it would have been all the better finished if further labour had been bestowed on effacing all the "beautiful" niggling. I have heard a painter say, "Now I am doing mischief. It would be better to let well alone. It is good enough."

On the other hand, anything like slovenliness must be avoided. This is especially true in our own art. An impressionist painter—a genuine one, I mean—may, and does, take infinite trouble to make his work look as though he had thrown his subject on to the canvas by a mere effort of thought, and by that means produces effects nearer to nature and more beautiful than any other way would afford, but this is the result of real hard work; his imitator, the sham impressionist—the one we see most of and are used to—makes some careless dabs of paint, and says, "How fine," and, helped a little by his own pose, trusts to the ignorance and reverence for fashion of his well-drilled audience to make a fine work of it. Much talk by these kind have done much mischief, but there are other causes of slovenliness.

Genius makes some people careless, but carelessness must not be taken for genius, and there is always the tendency of the black-crow, carelessness, to assume the peacock's feathers of genius; but sometimes genius suffers for not caring sufficiently for the humble means. Two of our most poetical photographers—we have had so few that I need scarcely say I mean Rejlander and Mrs. Cameron—cared little for manipulation, and suffered accordingly; indeed, the beauty of that part of the execution on which the effect depends of Mrs. Cameron's pictures owes much to the accident of what was then called a bad lens, the qualities of the badness of which seem now to attract the admiration and imitation of our best opticians. So the world wags. But she could *see*, and had the sense to take advantage of accident, unlike many of our original inventors of gelatine emulsions and other processes, who, if we are to believe them, had fame and fortune between their fingers, and had not sense enough to close their hands, and we hear a good deal of their "generosity" in giving away processes which never really existed until long after those who had failed to see had passed on, and somebody else had put to use crude experiments that had been allowed to run to waste. It is matter for curious speculation if we should ever have heard any more of early emulsion experiments if Bennett had not stewed his preparation of it. Our experience with the many slow, dry-

plate processes, more numerous in their time even than developers are now, was not exhilarating. We had a few operators who showed that beautiful work could be done with patience; they had to use much knowledge of chemistry and still more common sense. Even then their technique was no better than a pupil can do now the emulsion has been stimulated by fire, and nothing more. A complete list of the old dry-plate processes would show how ingenious and even imaginative we were in those days. Everybody modified everybody else's process, and with great originality tried almost every article of kitchen chemistry as a preservative except mustard and pepper; yet there was some good work done. The gum-gallic and collodio-albumen processes, in the hands of such men as Russell Manners Gordon, Mudd, of Manchester, and Lyndon Smith, of Leeds, produced pictures worthy of any time or process; but their lasting quality (in the sense that you did not tire of them) was due to the artistic knowledge of their makers. The last name I have mentioned is almost forgotten. He died young, being drowned while skating. He was certainly the most poetical landscape photographer of the time, and I think he took the first medal ever offered for photography in Great Britain. Technically, everybody can do better now without much technical study. The ghastliest failure of all the dry processes was the one about which most fuss was made—the tannin. The greatest discovery of the time was alkaline development, first published in THE BRITISH JOURNAL OF PHOTOGRAPHY by Mr. Leahy, of Dublin.

I will return to my subject by making the general statement that a picture has reached the greatest attainable perfection when it is "good enough;" but, when it reaches that altitude, is the problem so difficult of solution? If it goes beyond that uncertain point, degeneracy begins to set in,—

> "To add another hue to the rainbow. . . . .
> Is wasteful and ridiculous excess."

The question then, "Is it good enough?" should always be kept in mind, and be the touchstone of all you do. It is just possible that in course of time you will find yourself—being your own judge and jury—letting yourself off rather easily; this must be checked. Pass some unmerciful judgments and smash negatives: also think of the court of appeal, for which you may take the exhibition.

The question "When is a picture finished?" has caused much controversy. Mr. Whistler is one of the few who have endeavoured to reply. He says:—

"A picture is finished when all trace of the means used to bring about the end has disappeared.

"To say of a picture, as is often said in its praise, that it shows great and earnest labour, is to say that it is incomplete and unfit for view.

"Industry in Art is a necessity—not a virtue—and any evidence of the same in the production is a blemish, not a quality; a proof, not of achievement, but of absolutely insufficient work, for work alone will efface the footsteps of work."

In which is great wisdom if you read it rightly.

It is a very usual thing to say, I often say it myself, I hope with discrimination, "Never be satisfied." But I am not sure it is not like playing with edged tools. To wait for perfection is to lose all. It is better to do well what is possible, or even easily possible so that it is good enough, than to cry for the moon and fail. The most perfect state of mind for a photographer to attain is that which enables him to see instantly what will make a good picture, and to possess the courage to secure it without more ado. I am afraid that many photographers proceed in a very different manner; they may have eyes to see a good subject, but cannot satisfy themselves that it may not be made better, then they hesitate, and confusion sets in. They have come to the end of their knowledge, the crowning knowledge, which teaches them that it is good enough.

But to act with decision is nearly always only to be attained by long experience. The greatest painter I ever knew, and far and away the greatest true impressionist, put his picture on to the canvas in an incredibly short space of time; every touch was *right* in tint, and tone, and place, and never retouched, but all this was the result of the most minute study for very many years. I knew him from his early days, when he was an enthusiastic pre-Raphaelite, and, if he covered a square inch of canvas in a long day's work, he knew he had done well. In his later years his decision was absolute, and his painting almost as sudden as a snap-shot, but with this difference, every touch was applied with assured intention, while, I am afraid, the certainty of absolute intention seldom presses the button. This swiftness and certainty of touch could only be won in perfection, as my friend won it, by painful study and something very like hard labour.

The danger of too high a standard is like the search for truth, a compulsory impracticability is set up, and the result is that nothing is found good enough, and, as with the experimenters, everything ends in talk. Is there not an old song with a refrain that goes something like this?—

> "Little fools will love too much,
> But great ones not at all."

That little sentiment about expresses the situation. In judging whether they are "good enough," the weak, undertrained photographer is apt to take all his geese for swans, but the earnest student often goes too far the other way, and we lose what might have been of value. "When in doubt smash the negative" is a good rule, but there is something to be said on the other side. It depends on your temperament. If you trust yourself not to be too lenient, it may be well occasionally to put a doubtful negative aside for a month or two for further consideration. There is a household saying: "Put it away for seven years and it may come useful: if not, try another seven." Here is an example of how the saying has worked. After my pot-hunting days were over, when Exhibition committees racked their brains to find numerous classes for the encouragement of the worst photography, under the excuse of helping the young, I experimented in the direction of taking just another medal. To have any success, I found I had to look up some pictures that were cast away twenty years ago, which I did with success. They were "good enough;" better would have failed. I ought to add that, although the exhibition to which they were sent was a large one, there was no room for my newest and, I think, best efforts. They were not wanted. So photography was encouraged. H. P. ROBINSON.

FORM

How many otherwise good pictures are spoiled, or, at any rate, their appearance considerably impaired, by inattention to their shape, it is difficult to say. The final trimming may make or mar the result. A very presentable picture may frequently be cut from one which, if left of the original size, would be fit for nothing but the residues. So, if Röntgen rays, kinetoscopic projections, and colour photography have not hustled out every other subject, a word or two about trimming and form may be profitably considered.

Enlargements especially suffer from being left of inartistic proportions, there is such a disinclination to cut down for no fault but superfluity of subject, that the offending portions are retained from sheer reluctance to destroy beautiful detail, although that detail may, if left, seriously damage the appearance and art value of the whole subject. After practising photography for many years, I have experienced the feeling myself, and with sundry spasms of regret have sliced off little by little part of a pretty foreground until the picture was depleted of the full amount I had in the first instance thought would be necessary to remove. No matter how crisp and full of light the portion may be, providing it interferes with the proper balance of the subject, the shears must be ruthlessly applied, shutting our eyes to everything else but artistic form, which must, if possible, be secured at almost any cost, if we mean to have a picture and not merely a photograph. Of course, providing our work is a mere topographical representation, there are other considerations perhaps more important than the purely artistic, at the same time we must go as near as possible to the correct form, as a judiciously trimmed print will make as much better of an awkward subject as a badly trimmed one will make worse of it. Photographers more frequently err in respect of an unsuitable proportion of foreground than in any other manner, it may be too little or it may be too much, frequently the latter, especially when the idea is to get a picture the full size of the plate. I believe it is almost impossible to decide precisely and definitely as to the exact amount of subject that will make the best picture, by examining the image on the

focussing screen. It is not until we have the print before us that we can satisfactorily do this, and even then it takes more consideration than might be supposed would be necessary, masking off a slice here and a slice there until the final shape is determined upon.

The fact of having become accustomed to work with plates of definite sizes, and making our photographs to fill them up as much as possible, irrespective of other considerations, has been a prime factor in fostering the disinclination to cut the prints down. Mounts, too, being made for quarter-plate, half-plate, whole-plate, &c., sizes, has also influenced the makers of negatives and prints to make them to correspond with the mounts. I am not aware that any mounts are in the market that are not made in accordance with the usual sizes of the plates; that is, if we purchase them ready-made, with paste-down or lithographed tints, or ornamental lines and borders. A plain board will, of course, suit any shape, but a print, quite different in proportion to the usual tints, looks very ugly when attached to them, unless the prints are very much smaller than the tints they are laid on. Taking one size with another, I am inclined to think the general run of photograph is too square for landscape pictures, a somewhat longer shape would be preferable. However, this is a mere matter of taste, and is also in a measure regulated by the subject itself, or ought to be to a much greater extent than it is. When suitable, one of the advantages of a longer form is, that it increases the effect of extent. The shape termed panoramic gives the widest obtainable by trimming, and very often a photograph of this kind may be cut from a squared form with advantage, making a good picture, when the original was unsatisfactory. The proportions of a panoramic picture may be anything more than having the length twice that of the width. It is especially suitable for sketches of flat country, or river scenes when there are no tall objects in the near or middle distance; if there are, we are almost bound to adopt a square form. It is very seldom that a picture looks its best when the width equals its height; perfectly square or circular forms are only occasionally useful in landscapes, and even then the square is a doubtful advantage; probably the same subject in an oblong or oval would have a more pleasant appearance.

If we examine many artistic and delightful etchings and engravings, we find a portion bounded by the segment of a definite circle, or eccentric shape, and the rest vignetted; then, the outside form is unimportant, and is adapted to the exigencies of the case. In the book, or in whatever it may be mounted, the subject being a rule to itself, and independent of outside trimming. Tall, narrow forms are only applicable to tall narrow subjects, floral or *decorative* photographs, but for ordinary landscapes or portraits they are quite out of place. If three or four of this upright narrow shape are mounted side by side, the conditions are altered, and they assume the more ordinary character, the outside margins or lines of the *whole* impress one with the general effect, and not each individual picture, which singly would appear unsatisfactory, although, together, the effect is pleasant enough. As a rule, the horizon line regulates the amount of sky and foreground, the position of which is dependent on the height of the eye of the spectator, but in a photograph this rule is frequently disregarded. For instance, a photograph taken from a great elevation has frequently a much larger allowance of sky than it ought correctly to have; and one taken from a very low point of view may have much more. There is no absolute rule as to the proportion of sky or foreground above and below this line, but one-third of the width of the picture above the horizon, and two-thirds below it, is frequently adopted as a satisfactory adjustment. If the sky and landscape occupy exactly the same amount of space, there is a formality imparted to the picture better avoided,

When the upper part of the subject is well filled with clouds, a new interest is added, and then the horizon line may be lower, with advantage, than were the clouds non-existent. When the subject consists principally of near objects, without any distance, an imaginary line is drawn of the average height of a standing figure, and the print trimmed to suit it.

It is a very common practice to take the interior of large buildings from an unusually high standpoint, which gives an unreal effect, unless there is something that unmistakably indicates the position from which the view was taken. If an unobstructed view can be had from the floor, the general effect is, in my opinion, much better; even if we have to tip the camera, swing the back, and raise the lens, the point of sight still remains the same. There are occasions when something in the foreground has to be left out; that can only be managed by adopting a high standpoint, or it may be the position for which a photograph can be made is so restricted that the elevated position is imperative. This is, however, rather outside the subject of shape, which we are more especially considering, although the amount of floor space and roof has a very important effect on the results. Too much trimmed off the foreground makes a building seem to be sinking into the ground, and too little gives an up-hill appearance, to what should be the level. This up-hill look is frequently seen when churches and similar buildings are taken from a lofty gallery; it is not that the perspective is incorrect, but that the point of sight is unusual, and we get too little foreground to make a pleasant picture. This emphasises the necessity of having the horizon line of a suitable height, so that the perspective may not appear distorted, and applies to all architectural photographs, especially those that have to be taken from a near point of view, for no trimming will get rid of the effect of an unsuitable standpoint.

Whilst on the subject of architecture too great importance cannot be laid on the necessity of having perpendicular uprights obtained only by properly adjusting the *dark slide* so that it is truly vertical and level. In a print in which lines that ought to be upright incline one way or the other the trimming must in some degree be managed to counteract the inclination; supposing they incline inwards at the top, the trimming must be slightly inclined too, which will make the top edge of the print narrower than the bottom; in mounting the top can be stretched a little, so that the want of uprightness of the lines is remedied, and the mounted print will be more correctly rectilinear. Sometimes it happens that the uprights are so much out of truth that it is impossible to stretch the paper sufficiently; in this case the sides of the prints are better left slightly sloped, which will apparently reduce the inclination of the image, and so be better than accurate trimming that would have a tendency to emphasise the fault. Eccentric shapes are to be deprecated, even dome-shaped tops or very much rounded-off top corners interfere with the appearance of the subject; but, as for cushion shape, it should be abolished altogether, it was originally introduced to cut off defective corners, as also was the dome; but since we have cleaner manipulation there is no necessity for perpetuating a decidedly ugly shape. The only place in which such forms are not very objectionable is in the portrait miniature, which will permit the use of such shapes that for other kinds of photographs are quite out of the question; at the same time the trimming of portrait subjects is governed by the same rules as landscapes with a few additional precautions.

The oval form is a favourite one for vignetted heads and busts, and, when the boundary line is not too close to the subject, very suitable; trimming so that the head occupies the proper position both with reference to the centre and the pose is important. As a general rule, the head should be rather above the centre of the picture and never below it, and never trimmed so as to appear pitching forward or backward, as the case may be. If the body is included in the vignette, although the pose may be a leaning one, the picture should be upright: this especially applies to full-length figures. In portraiture, the trimming usually is secondary to the mounting, at any rate it is the determination of the outside boundaries of the subject, so it comes to the same thing. Square formsare generally more applicable to portraiture than landscape work; narrow oblongs, either horizontal or vertical, more rarely. In the first, a reclining figure or extended group, and in the second a single standing figure or small standing group are most appropriate. But for all subjects the shape is controlled by the composition as to length and breadth, the only imperative condition is that it shall be symmetrical.

EDWARD DUNMORE.

CO-OPERATIVE PHOTOGRAPHY.

THE photographic trade has expanded considerably of late years, and is rapidly adding to itself all the good and bad features of modern commercialism. This progress is shown by the complaints of employers that work is harder to obtain, profits are smaller, and that competition grows keener every day. The severe struggle to make photography pay is felt by assistants, who are also complaining of worse conditions, decreasing wages, and a general want of consideration in the treatment they receive from employers. Both master and man are seeking to form unions to protect their class against the aggression and sharp practices of the other. All this follows the ordinary laws of commercialism, and comes from the development of photography into one of the ordinary industries of the country. It indicates an advance from the nature of a simple unorganized cottage industry towards that complex and highly organized condition which is manifested in the factory system. The factory system has already made its appearance in some branches of photography, such as enlarging, view work, cheap portraiture, and retouching. Every branch is becoming specialised, and a worker no longer practises the trade throughout, but confines himself to a single branch. Such division of labour leads directly to the factory system, and large firms are becoming common who employ a great number of men com-

stantly working at one thing at which they are very proficient. These men are combined under one head or manager, and the firm thus becomes a most perfect machine for producing the best work at the cheapest possible cost.

This progress towards the factory system is the main tendency of photography; but at the present moment, due to various causes, of which Polytechnic teaching is the chief, there is also a minor movement away from the factory system and division of labour. Springing up everywhere we see a great number of small masters whose existence almost reduces the trade to the condition of a cottage industry. These master men employ little assistance outside their own families, and are satisfied if their incomes are a trifle better than the average wage. However, this condition cannot last, and it is only a question of time when many of these small masters will go down before the advance of the factory system. It only wants the men to arise with a faculty for organization to break up all these small capitalists.

The factory system, although having great advantages over individual production, is one of the evils of modern commercialism; it increases the greed of employers, reduces the workman to a machine, and destroys individual initiative. To remove these evils, and, at the same time, to secure the advantages of the factory system, the principle of co-operation was formulated. That principle maintains that all the workers in a society shall share in the management, receive the whole profits, and sustain the losses. Many so-called co-operative societies are merely so in name and not in principle, but there are also many flourishing societies in which the principle of co-operation is faithfully applied. Whether competing against the factory system or the more enlightened co-operation, the individual producer is at a disadvantage, and, under equal conditions, will be forced out of the struggle.

The majority of co-operative societies are simply distributors, and not manufacturers of goods. A little consideration will show why it is more difficult to carry on a co-operative productive than a distributive society, yet many of these co-operative productive societies are working well and supplanting the usual capitalist and factory system of production. For instance, in the boot trade at Kettering and other towns in the Midlands, these societies are managed, and the stock owned, by working shoemakers, who are, in consequence, much better off both as regards wages and conditions of labour than if working in a shoe manufactory.

A study of these various efforts has led me to the conclusion that similar methods could be most successfully applied to photography, and would add greatly to the prosperity and well-being of the workers engaged. Co-operative photography has never yet been tried, though I believe an attempt was made by a lady at Maidstone to form a society. This is somewhat remarkable, for few trades appear to be so peculiarly adapted to this method of production, and in few trades exist the same proportion of isolated master men who could work more economically and with more profit by combining their resources.

Photography would, of course, come under the head of co-operative production, the more difficult case; but, in spite of this, I will indicate some of the reasons which lead me to think it would add one more to the successes, and not the failures, of co-operation. Many attempts at co-operation have failed through bad work and mismanagement. In a photographic business both these defects can be immediately dealt with and remedied before much harm is done. Bad work carries its own condemnation with it, and bad management soon brings confusion. This confusion from mismanagement comes from the character of photographic work as a continuous process. To produce a photograph our methods must be so adjusted that they work like a well-arranged machine. When once the process is started, the slightest failure in a single part upsets the whole scheme. Operator, retoucher, printer are like the wheels in a watch, all must move if one is started. The sitter once taken, the remaining work must follow to completion. Photography, therefore, is, by its very nature, a co-operative process. This highly organised state of photography reduces the duties of management to a minimum, and we see this in actual practice, for the head of many a large business does the operating himself, as well as fulfilling his duties as manager. In general trade this would not be possible, the work of a manager demanding the whole time and attention of the principal. In photography, however, it is usual to combine the two functions of workman and manager. In a co-operative firm the duties of management could be still further simplified by each section doing its own, and in this way the co-operators would be at little expense for wages of management.

Bad work can always be detected, because, in past work, there is a standard to which present work can be compared; and, practically, it is a simple matter to keep up the quality of photographic work. The check of one worker upon another aids in this result, the operator soon detecting a falling off in the printing, and, a printer being the first to complain of faulty negatives, it is in the interest of each to secure the finest work from the other. By experience it will be found that a photographer can have no more exacting critic than those with whom he is working. From bad work and mismanagement, I see no good reasons to expect the failure of any scheme of co-operative photography, carried out by thoroughly qualified workers; in fact, these two main sources of failure are not such grave objections against co-operative photography.

The first gain from any scheme of co-operative photography would be financial. The principal difficulty to be met in all photographic ventures is the primary outlay for apparatus, accessories, and stock. Economy in these respects cripples all future action, and leads to complete failure; but this obstacle would be readily overcome by the intending co-operators adding their small means and making one respectable total. For example, many an operator or printer commences business with an outlay of about 100*l*. With this amount he is quite unable to purchase a very extensive outfit, and in consequence he is compelled to limit himself to a single class of work. For a large proportion of his trade he must hire apparatus, or put it out to be done, because he possesses no convenience for doing it himself. He is thus paying wages for work he might do himself had he the necessary appliances; but, supposing an operator, retoucher, and printer combine their means and start with an outlay of from 300*l*. to 400*l*., they can commence with a practically complete outfit, able to do all the ordinary work of the trade, and with the conveniences for doing a very large quantity. In the end this will pay, first, because they take the first profit, and the only profit, on all they do; secondly, because, when one branch is slack, another will be busy. The single man loses both these advantages, for he must share with many others the profits on a large part of his output.

A good outfit having once been secured, it will remain in working condition for some years, and the remaining heavy expenses of the business, to be constantly met, will be wages and materials. Leaving aside material, and considering wages, it will be seen that the co-operators would gain on this, the largest item of expenditure in a photographic business. Profits coming solely from the skill of the workmen, and varying with the rate of wages, it follows that, the members having every inducement to display the highest skill, the maximum profit will be made for the lowest wage; but, supposing the operators pay themselves the ordinary wage, they are then obtaining underpaid labour, and their profits swell by the exact amount of the difference between the value of capitalist labour and co-operative labour. Hence, in a co-operative society, in which the skill resides in the owners, the maximum of work is obtained for the minimum wage, and the largest possible profit is made.

In materials, likewise, a saving might be effected, and the waste reduced to the minimum.

To avoid waste of material, and also waste of time, is of first consideration in any business doing a high class of work, and we may be sure that the waste would be the least possible amongst workers who were directly interested in avoiding bad work. Waste of time, in like manner, would be small; every ray of daylight would be utilised, and in no trade is it so necessary to catch the fleeting sunshine as in photography—in fact, it is the first element of commercial success.

A society of photographers, working on co-operative principles, would thus be certain to attain, in a high degree, good work, economy, and dispatch, and these are the elements of success. Management and business acuteness are of secondary importance as distinct factors, for they are contained in the former. Workmen possessing the necessary skill are quite as able to secure the profits on that skill as any of the capitalists, totally ignorant of photography, who is at present exacting his wages of management.

In co-operation might also be found a remedy for some of those grievances of which assistants are repeatedly complaining, for there can be no question that, if nothing more were obtained, the improved conditions of the workmen would repay those who made the venture.

JOHN A. RANDALL.

EFFECTS OF BICHROMATES ON THE SKIN.

[Autotype Notes.]

QUESTIONS are frequently asked at demonstrations of the carbon process, and in the photographic press, as to the ill effects the bichromate salt is likely to have on its users. As carbon printing is rapidly extending amongst amateurs, as well as professionals, this seems a proper subject to be deal with in *Autotype Notes*. I am one who has suffered somewhat severely from the bichromate, as well as seen its effects, and non-effects, on others. It may here be mentioned that its injurious effects are comparatively rare, for I have many friends, who have worked the carbon process for many hours daily for twenty years and more, who have experienced no inconvenience whatever, while others, after a few months, have suffered severely. In no instance, however, have I known any trouble to arise where the process is worked only on an amateur scale.

The pernicious effects of the bichromate may be experienced in two ways, each distinct from the other; that is the opinion of Dr. W. B. Richardson, who has gone somewhat deeply into the matter, and my unpleasant experience quite confirms it. The first form is from the use of cold, strong solutions, such as those used for sensitising carbon tissue, paper for photo-lithography, &c.; the other from warm, dilute solutions, such as result from the continuous development of carbon prints in the same water. The former is only likely to cause trouble when there is an abrasion of the skin. Then the salt causes a smarting, may set up inflammation, cause festering, and ultimately, perhaps, ulceration. This latter often results in a deep and painful wound, exceedingly difficult to heal. The second trouble takes the form of a skin disease, and has been termed the "bichromate disease."

The first symptom of that is an irritation of the skin at the back of, and between, the fingers; slight at first, but, if neglected, increasing

later with the appearance of minute watery pustules. The skin then becomes dry, and afterwards exfoliates in bran-like scales. In the more acute stages of the disease mattery pustules form, the skin dries up like hard leather, and cracks into painful sores, particularly on the joints when bent. The skin then peals off in thick scales not unlike the shell of a shrimp. At this stage the itching is almost unbearable. It is, however, consoling that the bichromate disease is quite a local one, as it does not extend beyond those parts that come into direct contact with the solutions—the hands, wrists, and forearms, and there only where the skin is thinnest. I have never known the palms of the hands to be affected. In some phases of the disease it closely resembles a form of psoriasis, and has, before now, been mistaken for it.

Remedial measures.—In the first form of trouble, bathing the part in warm water, to which is added a little ammonia, followed by bread and water poultices; if taken in time, this treatment will usually effect a cure. If, however, it does not, and there is an appearance of ulceration, a doctor should be consulted without delay. With regard to the cure of the cutaneous disease, none is known to the medical profession. There is, however, a simple and efficacious one, namely, to avoid further contact with the bichromate, and nature herself will quickly work a cure. This may be done by working, in future, in indiarubber gloves.

Palliatives.—If, at the first stage of the disease, the affected parts have a little of the strong nitrate of mercury thinly applied, though well rubbed into the skin, and future contact with the bichromate be avoided, as a rule, no further inconvenience will be experienced. In the more advanced stages of the disease the following lotion will be found to greatly allay the irritation:—Alcohol, 5 ounces; carbolic acid (crystallised), 40 grains; glycerine, ½ ounce. If the skin is much cracked, this lotion may cause considerable smarting, in which case it may be diluted with water, or a dilute solution of subacetate of lead may be used instead. When the hands are washed, a carbolic oil soap is preferable to all others, as it allays the irritation, and at the same time softens the hard skin.

Precautionary measures.—After sensitising tissue, always wash the hands, before exposing them to a strong light, in water to which a little liquor ammoniæ has been added, and afterwards in warm water. The ammonia will take the stain out of the skin and nails. If there happens to be an abrasion of the skin, a smarting will be felt; then, after the washing, the place should be well sucked for a few minutes, and, if further pain is felt, the part must be poulticed at bedtime. After finishing development wash the hands and arms, if they have been in contact with the developing water, in warm water, using a carbolic oil soap and a hard nail brush. When these simple precautions are taken, and the old proverb, "Prevention is better than cure," is kept in mind, there is little, if any, fear of ill effects from carbon printing even when it is practised continuously and on a large scale. I speak feelingly on this point, as the total neglect of them for a long period entailed very serious inconveniences on myself.

E. W. Foxlee.

PHOTOGRAPHY OF COLOUR.*

The first step in the tricolour process consists in making three negatives of the subject, which are exactly alike in form, but each different from the others in that its opacity represents different kinds of colour. They are similar in this respect (which is true of all negatives), that all are transparent in regions corresponding to black in the original, and all opaque in regions corresponding to white; but here the likeness ends: one must be further transparent in regions corresponding to red, another in those corresponding to yellow, and the third in those corresponding to blue. To accomplish this, various kinds of sensitisation and filtration are necessary. The fundamental conditions to be considered are these: First, black will always be represented in a negative by transparency, and white always by opacity; and, second, the superposition of red, yellow, and blue transparent pigments on white paper produces black, while the absence of all three will, of course, leave the paper white; therefore, whatever be the process of printing, this common or black, representing transparency of the three negatives, must have corresponding to it the three pigment impressions; and, further, the common or white, representing opacity, must have corresponding to it none of the three pigments.

The transparency, then, of each negative represents the extent and degree of distribution of a particular pigment. The red-printing negative is transparent for black and red, but opaque for yellow, blue, and white; the yellow-printing negative is transparent for black and yellow, but opaque for red, blue, and white; and the blue-printing negative is transparent for black and blue, but opaque for red, yellow, and white. And, since opacity results from the action of light, while transparency means the absence of such action, it follows that each negative is produced by the action of white light *minus* that particular colour which is to be printed by it. In other words, the colour of the light which produces each negative is complementary to the colour of the pigment printed by the plate made from it. An ordinary plate will not serve to make one of the negatives. Such a plate, however, is almost invariably used, and this means the underlaying of all the red pigment with the yellow. An attempt to correct this error is made by using a red ink, containing more or less blue, to neutralise the warm effect caused by the yellow, but much of the luminosity, and many of the delicate effects, especially in the tints, are lost by this compromise. The artist's severe criticism of the process with regard to this point is certainly most just. This arrangement makes it absolutely necessary that the yellow should be printed first, and the aim seems to be to bury it just as deep as possible. Such should not be the case, but rather, provided the pigments are equally pure and transparent, any order of superposition ought to give the same result. But there will be no such fault if the third plate is properly sensitised and exposed.

A very interesting fact in connexion with this subject seems to have been quite overlooked. In producing coloured pictures in pigments, or by light in the lantern, distinct, visible colours are substituted for various regions of the spectrum with reference to correspondence of colour, either when separate or when in combination; consequently, the ultra violet light must be taken into account, so that its very marked chemical action may not result in the introduction of one or more of the colours in places and proportions wholly foreign to the original. This is of especial importance in making a coloured lantern picture, and must be provided against, by barring out the ultra-violet action.

The mechanical part of the process consists in preparing a plate from each of these three negatives, from which an impression in ink may be transferred to paper. Red, yellow, and blue ink is then applied to the respective plates, and the three impressions are successively superposed on white paper, care being taken to have them registered exactly.

Of the many perplexing problems which present themselves when it comes to the printing operation, we can say nothing here. To print from gelatine seems to be the easiest and most satisfactory method for experiment, although the difficulty in controlling the quantity of ink is a very serious one. If the right materials are used and the work is properly done, the printed picture thus produced will be a very exact reproduction of the original in colour. In actual practice there are a number of difficulties, as yet not entirely mastered, in consequence of which the majority of coloured pictures made in this way only approximate to the desired result. But this may, in all justice, be said of it, that the theory is sound, and that it is the only practical method so far discovered by which a permanent coloured picture can be produced by the aid of the camera. Photography is made, not only to select the proper colours, but to distribute them correctly as well. A simple illustration may serve to clear up some of the most difficult parts of the process. Let it be required to make a coloured picture of a bouquet of three flowers, one red, one yellow, and one blue, with a green leaf or two, all tied up with a white ribbon, and arranged with a black background; not a very artistic group, I must admit, but it best serves our purposes. The three negatives are taken and the printing plates prepared, each of which is rolled with its proper ink. The picture is to be made on white paper, and we understand that red, yellow, and blue pigments all three combined, produce black. What is each plate to do? It is evident that all three plates must spread ink over that part of the paper which is to represent the background, for that is black. Again, none of them must leave any ink on the space where the white ribbon belongs in the picture. The space for the red flower must receive red ink only, and so with the yellow and blue flower spaces, each of which must be printed with the one colour only, and, as for the green leaf space, that must receive both yellow and blue ink, and the resulting colour will be green; that is, each plate has certain portions of its surface blank, so that it does not obtrude its colour where it does not belong.

The production of a coloured picture with the lantern, by the use of three slides, is based on the same principles; but there are certain important differences in the negatives. That the differences are very considerable is not difficult to see; notwithstanding which, some eminent experimenters have come to the remarkable conclusion that a set of negatives which are correct for a coloured print are equally good for a lantern picture and *vice versâ*. This seems strange, for it may easily be shown that not a single negative in the print set is duplicated in the set from which the lantern slides are made. To make this set, an ordinary plate may be used for one negative, and it is exposed with a filter which cuts off the ultra-violet rays only. It corresponds very closely to the ordinary negative, but the ultra-violet action must be suppressed, else violet light will be substituted for what was invisible in the original, a very common fault with triple lantern pictures. The second negative is made from a correct orthochromatic plate, and a plate sensitised to red is used for the third.

The positive used in the red lantern is transparent, not only to the pure red, but also to the red in composition in the orange and yellow; th

* Concluded from page 346.

one in the green lantern transmits, besides the pure green, the component green in the orange, yellow, and blue; while the violet slide transmits pure violet and the violet ingredient of the blue.

There is one other point of interest in connexion with the so-called orthochromatic plate. The name signifies correct colour value. By that is meant a true representation of the luminosity, as measured by the eye, of the various parts and colours of the object photographed, when reproduced in the black-and-white monochrome. Photographic action is regulated far more by the kind of colour, the hue, than by luminosity. On the whole, the most luminous, and, generally speaking, the most effective colour ingredient in a coloured object or group is the yellow, the blue, as a rule, being inferior. If, then, any one colour class to be represented by light is to be luminous in the monochrome, it should be the yellow, and not the blue, as is the case in all ordinary photographs. Sensitisation to yellow and proper infiltration accomplish this result. It is always necessary to use a filter, however, in order to prevent the action of the blue-violet, which, together with the yellow, would destroy the balance in the monochrome, too much being represented as light. If the colours be grouped, as before, into the blacks, reds, yellows, blues, and whites, and two of these groups, one of which is the white, be represented as light, and the other three, which include the black, be represented as dark, the resulting monochrome seems to be well balanced.

An ordinary plate produces two groups, the whites and blues, as light regions; a good orthochromatic plate without a filter reproduces three groups, the whites, blues, and yellows, as light regions, while the same, with an orange filter, reproduces the white and yellow as light, and the blues, reds, and blacks as dark parts, thus preserving the balance and giving a true orthochromatic result in the monochrome.

In conclusion, it may be fairly claimed that the subject of photography of colour furnishes a most interesting and profitable field for investigation and study. It is of much worth to the scientist in dealing with the many subtle phases of the nature of light. Of no less importance is it to the artist, who frankly acknowledges the aid derived from the analysis and synthesis of light by this means, and its bearing on the nature of pigment colour. But the greatest value probably lies in the promise of its becoming a means of true education of the æsthetic sense with reference to that much-neglected, not to say greatly abused, aspect, the colour quality.

PROFESSOR J. STEWART GIBSON.

THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

THE Forty-first Annual Exhibition of the Society will be held from September 28 to November 12, 1896, in the Gallery of the Royal Society of Painters in Water Colours, 5A, Pall Mall East, London, S.W.

ADMISSION.

The Exhibition will be inaugurated on Saturday, September 26, by a Private View, followed in the evening by a *Conversazione*.

The Exhibition will remain open daily (Sundays excepted) from Monday, September 28, until Thursday, November 12. Admission (from ten a.m. till five p.m.), 1s. It will also be open on Monday, Wednesday, and Saturday evenings, when lantern slides may be shown; admission (from seven to ten p.m.), 6*d*.

Members have free admission at any time. They receive ten tickets for their friends, available either in the day or the evening, and can purchase additional tickets at half price. Members of affiliated societies can purchase tickets at half-price of their respective Secretaries. Every exhibitor receives a season ticket and a catalogue of the Exhibition.

MEDALS.

Medals will be placed at the disposal of the Judges. Exhibitors may state whether they wish their exhibits to go before the Judges in the Art or the Technical Section, or both. The Exhibition will be conducted according to the rules adopted at the Conference of Judges.

The under-mentioned gentlemen have been elected by the Members of the Society to act as Judges, and have consented to serve:—

Art Section.—Mr. F. P. Cembrano, jun., Colonel J. Gale, Messrs. B. W. Leader, A.R.A., G. A. Storey, A.R.A., and W. L. Wyllie, A.R.A.

Technical Section.—Captain W. de W. Abney, C.B., D.C.L., F.R.S., Messrs. Chapman Jones, F.I.C., F.C.S., and Andrew Pringle, F.R.M.S.

GENERAL REGULATIONS.

Photographs.—Each exhibitor must fill up the entry form supplied by the Society, and send it to the Secretary, Royal Photographic Society, 12, Hanover-square, London, W. Information as to particulars should be given with any work produced by a special process of the exhibitor.

At the back of each frame must be written the name and address of the exhibitor, with the title or description of the photograph, and the number (if there are more than one) to which it refers in the entry form. The front of the frame or picture may have the exhibitor's name, and the title of the picture, neatly inscribed upon it, *and this only*. To avoid damage to other frames, it is requested that all frames have sunken backboard, with the fastening nails not projecting, and the backs covered with thick brown paper.

Lantern slides will not be eligible for award unless both the negatives and slides are the work of the exhibitor. Frames will be provided for them.

Negatives, transparencies, photo-mechanical prints, stereoscopic work, photographs of purely scientific interest, and photographs coloured by scientific or mechanical means will be admitted. Photographs in Oxford frames, photographs already shown in any public Exhibition within the London postal district, and photographs coloured by hand are not eligible for admission. Excessive breadth in frames or mounts, silvered or oval frames, or projecting mouldings, are undesirable, and may prevent photographs from obtaining the position they otherwise merit. It is generally desirable that each photograph be separately framed.

All working up of photographs by hand, except mere spotting, is undesirable, and may cause the rejection of the exhibit.

Apparatus.—Each exhibitor must fill up the entry form supplied by the Society. A removable card must be attached to the exhibit containing the name of the exhibitor and the number to which it refers in the entry form. Attention is requested to this regulation, as, without it, the description of the apparatus may not appear in the catalogue. The exhibitor should fasten on each exhibit a small adhesive label containing his name only.

No apparatus will be admitted that has been shown in the Society's previous Exhibitions unless it has some new detail. All apparatus must be *concisely* described, and a list of the novel details given. Apparatus that has already been shown at London Exhibitions may be refused.

Sales.—The prices of the exhibits will be published in the catalogue so far as they are furnished by the exhibitors. Exhibits not priced on the entry form will be indicated as being "not for sale." Fifteen per cent. commission will be deducted on sales.

Foreign Exhibitors are invited to contribute. They will not be charged for wall space. The Society will provide frames or portfolios during the Exhibition for approved photographs.

Reception of Exhibits.—Exhibits sent by carrier must be *carriage paid*, and addressed to the Secretary, Royal Photographic Society, 12, Hanover-square, London, W., and must arrive on or before Wednesday, September 9.

Exhibits sent by hand will be received at 12, Hanover-square, W., only from nine a.m. to nine p.m. on Thursday, September 10, after which time and date no exhibit can, under any circumstances, be received for competition.

Very large frames and bulky or fragile apparatus may be delivered at the Gallery, 5A, Pall Mall East, if special arrangement, beforehand, is made with the Assistant Secretary.

Removal of Exhibits.—Exhibits received in packing cases will be repacked and dispatched as soon as possible after the close of the Exhibition.

Exhibits delivered by hand must be fetched away on the day appointed, due notice of which will be sent to the exhibitors.

Particular attention is requested to the removal of exhibits on the day appointed. If not taken away then, considerable expense will be incurred in removing and warehousing. This expense will be charged to the exhibitor. Exhibitors can have their pictures packed in a case and sent by carrier, by giving instructions to the Assistant Secretary and paying the cost.

CHARGES.

The privileges mentioned below are accorded to members of the Society whose subscriptions are not in arrear, and are granted to them in their individual capacity only. A firm or company exhibiting in their corporate capacity is treated as a non-member, although one or more members of the firm may be members of the Society.

Wall Space.—No charge will be made to members of the Society. To non-members a charge of 1s. per square foot, and to members of affiliated societies a charge of 6*d*. per square foot, will be made for wall space. To obtain this reduction, the entry form must be accompanied by the membership voucher bearing the affiliation stamp. The minimum charge in each case is 5*s*. Lantern slides and transparencies will be charged as for pictures. Twelve lantern slides are calculated as equal to one square foot. Postal orders to pay for the wall space required must accompany the entry form, and, should any of the photographs not be accepted, the due proportion, in excess of the minimum charge, will be returned. The charge for wall space to those exhibitors who may be elected as members of the Society before the end of the year will be remitted, and the amount paid credited to their entrance fee and subscription.

Apparatus.—The apparatus will be under the personal supervision of an attendant, who will be ready to furnish explanations to visitors during the whole time the Exhibition is open. Each apparatus exhibit will be described in the catalogue, and, where thought desirable, illustrated. The charge to members will be at the rate of 5*s*. for each piece of apparatus or square foot of table or floor space (whichever is greater), with a minimum charge of 10*s*. The rate to non-members will be at 10*s*., with a minimum charge of 20*s*. These charges must be enclosed with the entry form, or the exhibit will not be received. If a case of apparatus is accepted for exhibition, each item contained in it will be treated as a

separate exhibit and so catalogued and charged for, except when the items naturally form a single exhibit; as, for example, a hand camera, including the camera and lens, or an apparatus with parts of it shown separately to illustrate its construction.

CONDITIONS.

It is to be distinctly understood that the sending of exhibits signifies acceptance by the exhibitor of the decision of the Council upon all matters connected with the Exhibition as absolute and final.

The Council do not hold themselves responsible for any damage that may happen to the exhibits while in their custody, but every precaution will be taken to ensure their safety and prompt return to the owners at the close of the Exhibition. They reserve the right to reproduce in the catalogue any of the pictures exhibited.

OPTICAL LANTERN.

Photographic lantern slides will be shown by means of the Society's optical lantern during the Exhibition. The loan of slides for this purpose is invited. They must not exceed three and a quarter inches in height, and, to facilitate selection and arrangement, they must be delivered at the Gallery not less than three days before the evening of their being shown in the lantern. If sent by carrier, they should be addressed to the Secretary, Royal Photographic Society, 5A, Pall Mall East, S.W., and they will be returned within seven days of their exhibition.

Blank entry forms and any further information respecting the Exhibition, also nomination forms for membership, can be obtained from the Assistant Secretary of the Society, 12, Hanover-square, London, W.

Our Editorial Table.

MODERN OPTICAL INSTRUMENTS.

By HENRY ORFORD. London: Whittaker & Co., 2, White Hart-street, Paternoster-square.

MR. ORFORD is already favourably known by his volume on *Lens Work for Amateurs* which established his capacity for dealing in a practical manner with the optics of photographic lenses. The present book is mainly concerned with the study of optics as applied to the human eye, the aberrations of which, as well as its properties as an optical instrument, form an introduction to a series of chapters on the employment of the ophthalmoscope; retinoscopy; and spectacles and their selection. It will thus be seen that the little work, which is clearly and concisely written, is calculated to prove serviceable to those making a study of the aberrations of the eye and the remedial treatment therefor demanded. Chapters on the optical lantern, the stereoscope and the spectroscope conclude the volume, which is freely illustrated, and is got up in the praiseworthy manner one is accustomed to look for in Messrs. Whittaker's publications.

WALNOTINE.

Walnot & Co., 917, Garscube-road, Glasgow.

"WALNOTINE" is the name of a two-solution developer, sample bottles of which Messrs. Walnot & Co. have sent us for experimental use. It answers admirably, yielding with correctly exposed plates bright and well-gradationed negatives. It admits of repeated use, retains its colourlessness for a considerable time, and should be appreciated by amateurs and occasional workers.

CATALOGUE RECEIVED.

Andrew H. Baird, 37, Lothian-street, Edinburgh.

MR. BAIRD has deservedly won a prominent place among Northern photographic dealers, and this neatly turned-out catalogue testifies to the acumen with which he selects his stock. Particular mention is made of the Lothian cyclist camera: the Todd-Forret magnesium lamp (excellent examples of exposures made therewith being given); and many other of Mr. Baird's specialities, which sandwich, as it were, a well-selected assortment of general apparatus and sundries.

EDWARDS' PLATES AND FILMS.

B. J. Edwards & Co., The Grove, Hackney.

MESSRS. EDWARDS were early in the field with the manufacture of gelatine dry plates, and it says much for the good qualities of these plates and the reputation of the firm that, after the lapse of so many years, they should enjoy such a large measure of public esteem. During the last few weeks they have given us the opportunity of trying some of their plates and films of most recent manufacture. As is well known, Messrs. Edwards issue two series—isochromatic and ordinary—each in three rapidities, medium, instantaneous, and snap-shot. It is late in the day to advert to the colour-correct rendering qualities of the isochromatic plates, which were long ago recognised as putting a great power in the hands of the photographer having objects in colours to take. The slower kinds of plates appear to be very thickly coated, and thus become of great service for long exposures and interior work. The "snap-shot," ordinary and isochromatic, are exquisitely sensitive, and the grain bears the scrutiny of magnification extremely well. Both plates and films possess great mechanical evenness, are easy to develop, and, as regards the "snap-shot" (probably as quick an emulsion as there is) well withstand development veil, that bugbear with very rapid plates. Altogether, Edward's plates highly deserve the popularity they enjoy.

News and Notes.

ROYAL PHOTOGRAPHIC SOCIETY.—Ordinary Meeting, Tuesday, June 9, at eight p.m., at 12, Hanover-square. *Cellulose and its Derivatives*, by Messrs. Cross and Bevan. *On Printing Densities*, by Captain W. de W. Abney, C.B., F.R.S.

SOUTHPORT SOCIAL PHOTOGRAPHIC CLUB.—The Sixth Annual Exhibition of members' work will be held from October 26 to 31 inclusive. Five awards (a volume of the *Magazine of Art*, two value 10*s.* 6*d.*, and two value 5*s.*) will be placed at the disposal of the Judges, to be given, if the work merits it, for the artistic and technical excellence of photographs and transparencies.

KIMBERLEY CAMERA CLUB.—Honorary officers, 1896-97. *President:* Mr. James Lawrence, M.L.A.—*Chairman:* Mr. Montague Thane.—*Vice-Chairman:* Mr. Charles Howie.—*Council:* Messrs. J. Childs, J. Bennett, E. Goffe, S. Turner, and P. H. A. Pope.—*Lanternists:* Messrs. J. Childs, E. Goffe, and J. W. Lawrance.—*Secretary and Treasurer:* Mr. Frank H. Hancox, P. O. Box 305, Kimberley.

WE regret to record the death of Mr. James Charles Heavisida, who died on the 25th ulto., in his seventy-second year. It is the older readers of THE BRITISH JOURNAL OF PHOTOGRAPHY who will remember Mr. Heaviside. He was for twenty five years the trustworthy manager for, and confidential friend of, the late J. H. Dallmeyer and of his son and successor. Mr. Heaviside was a man of considerable artistic and literary ability, and no mean musician. His imposing personality and charm of manner eminently fitted him for the commercial duties in which he was engaged, and gained for him a wide circle of friends. He retired from active business life in 1884, and had suffered for some years from indifferent health. The immediate cause of death was bronchitis. In addition to the personal friends and relatives who attended the funeral, some of the oldest hands from the firm of Dallmeyer attended as a last mark of affection and respect.

THE X RAYS.—The General Electrical Association of Berlin announce that they have succeeded in so improving the Röntgen tube as to render it possible for the internal structure of the head, the larynx, and more especially the action of the respiratory organs and heart, to be observed direct on the fluorescent screen. A practical demonstration will be given at the Surgical Congress. Mr. Edison gave a semi-public exhibition of his new light at New York last week. It was variously described as "luminous ether light" and "X ray light." The lamp used was an ordinary Crookes' tube, about five inches long, coated inside with some kind of crystals easily obtainable, the exact nature of which the inventor refused to disclose. To an interviewer Mr. Edison said: "The X rays undergo some organic change in passing through the crystals, and practically no heat is generated. Thus, all the energy which in an incandescent lamp is lost in heat is turned into light," resulting in an economy, it is understood, of seventy-five per cent., one of the new lamps of only four-candle power giving a light equal to that obtained by the usual sixteen-candle power incandescent lamp. The commercial value of the discovery remains to be demonstrated.

Patent News.

THE following applications for Patents were made between May 20 and 27, 1896:—

KINETOSCOPE.—No. 10,773. "Improvements in Apparatus for Taking and Exhibiting Successive Photographic Pictures." A. N. PETIT.

TRIMMING PRINTS.—No. 10,872. "The 'Practical' Trimming Glass for Trimming all kinds of Photographic and the like Prints, Drawings, and Illustrations." T. R. WATSON.

PHOTOCHROMY.—No. 10,994. "A Process of Reproducing Photographs of Oil Paintings." S. RAPPA and J. BERRY.

FINDER.—No. 11,001. "A Finder or Camera Obscura for Photographic or other purposes." J. AIRS.

CAMERA.—No. 11,015. "Improvements in Photographic Cameras." H. W. G. PLUNKETT.

ARTIFICIAL LIGHT PHOTOGRAPHY.—No. 11,262. "Improvements in connexion with Artificial-light Photography." C. E. ELLIOTT.

DEVELOPING SOLUTIONS.—No. 11,306. "Improvements in Photographic Developing Solutions." Complete specification. J. HAUFF.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

June.	Name of Society.	Subject.
8	North Middlesex	Demonstration on Rough Bromide Paper. S. H. Fry.
9	Birmingham Photo. Society	Exhibition of Competition Pictures taken upon the Excursions to Marston Green and Kenilworth during April.
9	Hackney	Discussion on previous Lectures.
9	Royal Photographic Society	*Cellulose and its Derivatives.* Messrs. Cross and Bevan.—*On Printing Densities.* Captain W. de W. Abney, C.B., F.R.S.
11	London and Provincial	*Who Uses Quick Plates for Hand-camera Work?* W. D. Welford.
11	Borough Polytechnic	Excursion: South Norwood and Shirley.
13	Leytonstone	Excursion: Loughton and High Beech. Leader, C. A. Russell.
13	Oldham	Excursion: Bramhall Hall. Leader, C. A. Hempstock.

ROYAL PHOTOGRAPHIC SOCIETY.

MAY 26,—Technical Meeting,—Mr. E. Cecil Hertslet in the chair.

Mr. LAMBERT MATTHEWS, of the Scientific Hand Camera Company, exhibited and described the "Scientific" hand camera for 5×4 plates, constructed on the twin-lens principle, and adapted for use with dark slides, roll-holder, or with a changing box, and fitted with a rapid rectilinear lens by Beck and a Thornton-Pickard shutter.

The subject for consideration was

APPARATUS FOR PHOTOGRAPHING ON SMALL PLATES

(less than quarter-plate), and several instruments were exhibited.

Mr. E. Clifton showed an early form of binocular camera, which was given to him by the late Mr. William Spicer, of Clerkenwell, and which was probably one of Geymet's cameras.

Mr. T. BOLAS said that in Geymet's cameras the changing mechanism contained a disc, in which an aperture was cut, and this was revolved to bring a different part of the plate into position for exposure.

The ASSISTANT SECRETARY (Mr. Child Bayley) had an opportunity of examining one of Geymet's instruments, which was in the possession of the late Mr. Traill Taylor, and the camera shown by Mr. Clifton appeared to be identical with it.

Mr. Clifton also showed one of Mayfield's ebonite hand cameras belonging to Mr. Noel Cox, in which several modifications had been made, including the addition of a specially constructed shutter by Newman & Guardia, working from $\frac{1}{5}$ to $\frac{1}{100}$ second, and changing boxes to hold twelve plates or twenty-four films.

The HON. SECRETARY (Mr. Chapman Jones) showed a small camera from the Society's museum which bore the name "Bryceson, Edinburgh," and was provided with a Dallmeyer medallion lens, which had been identified as having been made in February 1870, working at *f*·2. The camera appeared to be identical with the form used by the late Professor Piazzi Smyth. It was adapted for the silver-bath process, and comprised a square, water-tight receptacle, each face of which carried a plate, and which revolved in order to bring the plates successively into position. The lens was mounted in a spring jacket, and could be adjusted at four different points, presumably for focussing at varying distances. The exposed portion of the plate was an inch square, but the bath would accommodate one three inches in length, which was exactly the size of the ordinary micro slip used by Professor Smyth. Mr. Chapman Jones said he had always advocated the use of the half-quarter plate for hand cameras, which possessed many advantages, and he showed a cutting board which he had designed for facilitating the division of quarter-plates into two equal portions.

Messrs. Newman & Guardia exhibited a hand camera, constructed to carry twelve plates or twenty-four films of half-quarter-plate size, and fitted with a Zeiss lens of 3¾-inch focus, and working at *f*·6·3.

The HON. SECRETARY thought nearly all hand cameras were made the wrong shape; in all changing arrangements there must be a little space on one side of the plate, and most makers put that extra space on the narrow side, thus producing a "lumpy" parcel, instead of a flat one.

Mr. G. W. TOTTEM, of the Eastman Company, showed the Pocket Kodak, and specimen negatives, prints, and enlargements. As an instance of the popularity of this instrument, he mentioned the fact that during last week 1300 cameras and 26,000 film cartridges had been sold.

Mr. LEON WARNERKE spoke highly of the performance of the camera during his tour on the Continent in February and March last, and said he had been able to obtain fresh supplies of film in small towns in various parts of France, Germany, Italy, and Switzerland.

Mr. J. W. Barlow, representing Messrs. Beck, exhibited a No. 1 Frena; and Mr. Middlemiss sent a camera for enlarging from small negatives.

THAT DEVIL AGAIN.

Mr. LEON WARNERKE said that at a recent meeting some members had said they did not know what "devils" were, and he had therefore brought for inspection a plate and print in which "the devil himself" was plainly visible. Asked for an explanation to account for his majesty's appearance, he said he could offer no theory, and wiser men than he had been unable to fathom the mystery.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 28.—Mr. R. Beckett in the chair.

Mr. Edward Simpson was nominated for membership.

The HON. SECRETARY reported that he had written to the County Council and the Hampstead and St. Pancras Vestries as resolved in the matter of the operations on Hampstead Heath, and had received a letter from the last-named stating that their Committee, having gone into the matter, recommend that no action be taken. The Hon. Secretary referred to some experiments conducted by himself and Mr. Wiss as to whether the use of ruby glass as a support for the emulsion instead of ordinary glass would tend to avoid halation, and said that the films had now been stripped for examination, as, owing to the density of the ruby glass, this was not possible before. He thought that the negative on the ruby glass showed a certain amount, though less, of halation, and drew attention to the fact that the ordinary plate in the high lights was very much thinner than the ruby, although they both received identical exposures and development, and were of the same batch of emulsion.

A discussion took place on the subject of the accelerating action of air on a plate during development, and,

Mr. WELFORD detailed a case in his own experience where a plate, after long immersion in the developer, showed no sign of an image, but, on subjecting the same to the action of the air for five minutes, the silver was found to be reduced almost through to the back. His opinion was that the more the plate was taken out of the solution and exposed to the air, the quicker would the action be.

Mr. HENDERSON referred to the practice of washing the plate in water two or three times during development, so as to get a softer negative, and thought you might just as well dilute the developer at the beginning instead.

ON THE WASHING OF PRINTS WITHOUT RUNNING WATER.

Messrs. HADDON and GRUNDY, in a paper on the above subject, after referring to the result of their investigations on the washing of albumen prints in running water, which showed that the usual two hours' washing was unnecessary, as all the silver and hypo capable of elimination by water could be washed away in twenty minutes, said they had been since endeavouring to decide the number of changes of water necessary for the perfect washing of a print when running water was not available. Albumenised paper was sensitised on a neutral nitrate of silver bath, dried, and cut into pieces of equal size. These pieces were then washed in several changes of water until all milkiness had gone, when they were immersed in a litre of twenty per cent. of hypo for twenty minutes, with constant movement, after which they were removed to the washing water. The authors decided that the amount of washing water should bear a fixed ratio to the area of the paper, that decided on being one cubic centimetre of water to every square centimetre of paper surface, which, with the quantity of paper to be treated, gave a quantity of 2445 cubic centimetres of water. At the end of five minutes' immersion, with constant movement in this water, two pieces, equal to a quarter sheet, were withdrawn for the estimation of the quantity of silver therein contained, and dried, the remainder being placed in another vessel containing 2201 cubic centimetres of water, the difference being allowed for the lesser quantity of paper, so as to keep the same ratio of paper area to washing water. The same process was observed through ten changes of water, a quarter sheet being withdrawn at each change for estimation. At the same time tests were made of the value of the various methods for ascertaining whether a print has been properly washed by examining the wash water, a quantity from each change being set apart for this purpose. The tests adopted were the permanganate of potash, iodide of starch, and sulphuretted hydrogen methods, the first two for the presence of hypo, and the latter for detecting the silver. Several test tubes were taken, two being filled with ordinary tap water, and to one of them one drop of permanganate of potash solution was added, which coloured the water a faint pink. The other test tube was likewise treated, iodide of starch replacing the permanganate. The tints of these were fixed on as standards, and to test the wash water some was placed in a test tube, and the number of drops of permanganate and iodide necessary to bring it to the same tint as the standard tubes showed roughly the quantity of hypo in the water, and the progress of the washing. The sulphuretted hydrogen was added to the wash water in a test tube, and, after standing some time, on looking down the tube, the presence of silver was indicated by a brown tint. The amount of silver still present in the paper after each washing was estimated by allowing them to dry, and burning to ashes in a dish. This ash was boiled in distilled water with several changes, and then with dilute nitric acid to dissolve the metal, filtered, and the residual ash treated with strong ammonia to dissolve any silver chloride possibly formed by impurities in the nitric acid. This was neutralised by nitric acid, and added to the former solution, which were then together heated to boiling point, and a few drops of hydrochloric acid added to precipitate the silver. The chloride thus formed was allowed to settle, filtered, and washed, and then estimated in the usual way. It was found that, after the third change, the amount of silver remained constant, and no effect was produced with further washing. It was likewise found that the third change was the last in which any hypo could be traced.

When it is remembered that the function of the water is not to dissolve the silver salts, but to replace the sodium hyposulphites, which already contain the silver in solution, it is easier to understand that three changes were sufficient to extract the soluble silver salts from the paper, although at first it may seem extraordinary. The authors state that their experiments show that five changes are sufficient to completely eliminate the hypo and all soluble silver, but they drew attention to the fact that, throughout, the paper was continually on the move.

The CHAIRMAN thought it evident that Messrs. Haddon and Grundy had given a great deal of attention to these experiments. Mr. Henderson had found that long washing was injurious. Whenever he found prints fading, it was generally traceable to this cause, and with this he agreed. It was not only utterly useless, but extremely harmful, and lime might be deposited in the paper. With gelatine papers the effect would be worse.

Mr. HENDERSON repeated that the prints had been kept in constant motion, and that this greatly affected the result. He detailed a method of washing prints, introduced by Ross & Pringle, of Edinburgh, where the prints were suspended from cross pieces in tanks, and the water automatically syphoned off, leaving the prints to drain, the tank subsequently refilling. With reference to long washing, it used to annoy him to have prints returned faded, but he found it to be due to the bronze in the mounts. He was of opinion that fixing baths of too great strength were used, and that by so doing a fading action was set up, and an element of failure introduced. He had purposely tested the merits of strong and weak fixing solutions under the same conditions, and was convinced of the error of using strong solutions.

Mr. GRUNDY said in washing prints most people looked at it as if they were dissolving something out instead of simply replacing. With albumen paper, it is impossible to fix out with hypo the remaining silver, but, in the case of two brands of gelatine paper he had tried, you can get rid of all traces of it.

Mr. HENDERSON queried whether some of the gelatine papers did not contain albumen.

PHOTOGRAPHIC CLUB.

MAY 27,—Mr. A. Mackie in the chair.

After some formal business, the CHAIRMAN asked the members to welcome the Rev. F. C. Lambert as a visitor.

Mr. Welford passed round some strips of pocket Kodak negatives from exposures which he had lately made in Holland.

Mr. Snowden Ward passed round some samples of colour printing, which were called Synchromie. These were made by Count Turati's process, and the point of novelty consisted in the fact that the seventeen colours of which the print was composed were printed at one impression. The advantage appeared to be a great saving of time in the printing operation, general economy, and the certainty of accurate register.

Mr. FOXLEE queried whether commercially the three-colour printing process was in successful operation, and whether the best colour work by typographic methods was not obtained with a larger number of printings.

Mr. WARD said that undoubtedly the three-colour process in this country was generally used for the cheaper class of work, whereas in America they had laid themselves out to do the highest class of work with it, regardless of commercial considerations. He thought that the more expensive colour printing was usually done by processes involving a larger number of separate printings.

Mr. F. HAES then gave his demonstration of

THE DAGUERREOTYPE PROCESS.

He first of all gave a short account of the early workers, and said that, although Daguerre had given his name to the process, it was extremely probable that Niépce really deserves the credit for the discovery. Daguerre had first used iodine only for sensitising his silver plates, and the resulting films were terribly slow, a portrait in full sunshine, and with a large aperture, requiring sometimes more than half an hour's exposure. In 1839 Goddard found that the vapour of bromine, in conjunction with iodine, largely increased the speed of the plate, and this combination afterwards obtained. The Daguerreotype process was essentially one depending upon the man as well as the material, and in this is quite the opposite to our present "press-the-button" methods. Everything had to be of the utmost purity, and the greatest care, cleanliness, and regularity of method, manners, material, and temperature had to be observed. Mr. Haes then proceeded to demonstrate the working of the process. He polished his silver plates with tripoli, and buckskin or cotton velvet buffs, which he had made himself for the occasion. Having prepared the plate and described the use of the sensitising box, which contained an arrangement of reflectors and mirrors, by which the progress of the sensitising could be watched, the lecturer proceeded to prepare a plate and to point out the changes in colour as they took place. He also pointed out that, when perfectly sensitised, by a skilled use of the combination of the vapours of bromine and iodine in separate vessels an extremely sensitive film resulted, almost as sensitive, in fact, as a modern dry plate. On the other hand, the fineness and sharpness of the lines of the pictures, and their extreme delicacy were unapproachable by modern methods. After sensitising, the plate was developed over the vapour of heated mercury, and the principle of development was clearly indicated by the fact that, whilst the change in the iodide film took place in a marked degree where the light had acted upon it, on the other hand, there was no deposit of mercury, or any alteration in character, of the polished silver film of the copper plate where it had not been attacked by the bromine or iodine vapour. Mr. Haes described the completion of the picture by the Fisot fixing method.

A very interesting evening was suitably concluded by an exhibition of old Daguerreotypes from the museum of the Club, the lecturer being well plied with interesting questions of a technical character. In the course of these questions it was stated that the Daguerreotype process was in use in America for observatory work so recently as within the last ten years, and that bromide of potassium was listed at 4*s.* per ounce, and hyposulphite of soda at 6*s.* per pound, in the days when Daguerreotype was the photographic method.

Mr. FRY proposed a vote of thanks to Mr. Haes for all the trouble he had taken in working up the methods and almost-forgotten details of the oldest and most interesting process. Mr. Haes had been exceedingly kind to the Club in this matter. First he had presented a complete set of apparatus peculiar to the process. In the second place, by taking a great deal of trouble and incurring some further expense, he had given the members a capital insight into the actual technicalities of the process itself. This was most interesting to the younger and older members alike, and Mr. Haes had added still more to the debt of gratitude which the members individually, and the club generally, owed him.

The CHAIRMAN said that no formal seconding of a proposition, which was so obviously acceptable to all present, would be put by him to the meeting, which thereupon signified its complete accord by hearty applause.

Mr. HAES expressed his thanks and the pleasure it had afforded him to give the demonstration.

Brixton and Clapham Camera Club.—May 19, Mr. W. Thomas (Vice-President) in the chair.—Under the arrangement for the interchange of demonstrations between affiliated societies, a paper on

ENLARGED PAPER NEGATIVES

was read by Mr. H. STUART, of the North Middlesex Photographic Society. The following is a brief summary:—Paper, as a support for the negative photographic image, was used before glass, and is therefore no novelty, but the process gradually fell into disuse, and has become almost extinct. Considering, however, the improvement in the manufacture of papers and emulsions during the last two or three years, I am led to believe the method worth resurrection. My experiments have been confined to the production of enlarged negatives on paper from small positive prints, and I think the process has its recommendations. The way I set to work is to take a contact print on smooth bromide or gelatino-chloride paper, and squeegee the same on a piece of glass, say, a well-cleaned spoilt negative. Gelatino-chloride paper is perhaps the best, and the print need not be toned, but simply fixed and washed, and, owing to the non-actinic colour of the untoned image, a weak print will be found to copy well. By mounting behind glass, as mentioned, the grain of the paper will give no trouble, at any rate for enlargements, such as from quarter-plate to 12×10. The print is then enlarged to the required size by reflected light, the usual form of daylight enlarging apparatus being well adapted for the purpose. In consequence of the faintness of the image, the ground-glass screen is unsuitable for focussing, which must be done with an eyepiece on the aerial image itself. It is also well to mark once for all on the baseboard of the camera the correct distance from the lens for, say, 10×8, 12×10, and 15×12 in enlargements, thus saving adjustment on future occasions. Slow bromide paper is the substance on which the enlarged negative is taken, and it must be placed behind a piece of glass in the dark slide so as to be kept flat. Exposure is prolonged and varies of course with the degree of enlargement, strength of light, &c. Enlarging, for instance, from quarter-plate to 12×10 with *f*-16 may take from a quarter of an hour in summer to three hours in winter, but by using an actinometer, as in carbon printing, the question of exposure is reduced to a simple one, and no difficulty need occur. After exposure, the bromide paper is developed (preferably with hydroquinone), and an enlarged negative is the result. This may be waxed over to render more transparent and to fill in the grain of the paper, or may be used as it is if the grain is not objected to. Waxing is a tricky matter and requires practice. Coating with a brush dipped in melted paraffin wax is one way; others are, soaking the negative in a hot solution of the same, or brushing over a solution of wax dissolved in some solvent (as benzine) which quickly evaporates, leaving the paper translucent. The negative being now finished, a positive may be printed from it in gelatino-chloride, platinotype, carbon, or other desired process. In conclusion, the following points may be claimed in favour of the system: *Economy.*—Bromide paper is less than half the cost of glass plates or celluloid films; is not liable to breakage, a not uncommon mishap in printing from large glass negatives; is lighter than glass and stores in less space. *Ease in Retouching.*—The paper negative can be spotted or retouched with far greater ease than a glass negative or transparency. *In Carbon Printing*, by single transfer, a reversed negative is unnecessary, the loss of sharpness caused by printing through the paper being very slight. To add force to his description, Mr. Stuart showed two or three dozen enlarged negatives, together with the originals from which they were taken, and also enlarged prints in bromide, gelatino paper, and carbon. Mr. Stuart said some of these were examples of what to avoid, being mistakes which might be expected in the experimental working of a process about which little information could be obtained from the ordinary photographic sources. Be this as it may, many of the results shown were really exquisite, and several present decided to give the process a trial.

Croydon Camera Club.—May 30.—A party of thirty members of the Club, in charge of the President (Mr. Hector Maclean, F.G.S.), visited, by special permission of the Mayor of Croydon, the new municipal buildings lately opened by H.R.H. the Prince of Wales. Cameras were busily employed from 2.30 to about 7.30. Besides the various law courts, the council chamber, and public library, members found that the grand staircase, the Mayor's parlour, the steam heating apparatus, the clock machinery, and bird's-eye views of Croydon from the campanile gave them promising subject-matter. By kindness of the Mayor tea was provided, at 5.45, in one of the committee-rooms, in the course of which the President proposed the Club's hearty thanks to Mr. F. T. Edridge (the Mayor), for having afforded all so acceptable an opportunity of picturing the magnificent Town Hall. Seconded by the Vice-Chairman (Mr. J. Nooks), the above was carried with much fervour.

PAYMENT FOR REPRODUCTIONS.

In the course of his speech to members, Mr. Maclean drew attention to the fact that the proprietor of a local journal specially invited *amateurs* to submit photographs for publication of the Royal visit, &c. He explained to those assembled that the trade custom was to not accept less than 10*s.* 6*d.* per print, and urged upon members of the Club not to undersell each other, or spoil the market, by offering prints for less than the standard minimum. These re-

marks, pointed by personal experiences, were not only well received, but seemed to have made an enduring impression upon the large gathering. Before dispersing, Messrs. Underhill and Bown took negatives of the party grouped upon the Town Hall steps.

North Middlesex Photographic Society.—June 1.—Mr. PITHER opened a discussion on

ARCHITECTURAL PHOTOGRAPHY.

He brought down numerous engravings to illustrate his remarks of various styles of architecture, and suggested that the Society should make a study of old buildings, churches, &c., and photograph special parts of interest, not only taking general views of the subject, and suggested that a special outing should be held with this object in view, to see how the idea worked. A lengthy discussion took place, in which a number of members joined, and at the end of the meeting the opinion of those present was taken as to the advisability of this step. Mr. CHILD BAYLEY proposed and Mr. COX seconded that "it is desirable that an outing on the lines suggested by Mr. Pither should be held." A number of members promised to assist if called upon

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

BROMIDE PAPER FOR NEGATIVES.

To the EDITORS.

GENTLEMEN,—Replying to "W. R. F." in your issue of May 22, I would advise him to apply to the Eastmau Photographic Materials Company, Limited.

I have a roll-holder in which I wished to use bromide paper, and I applied to the above firm, asking them if they would supply me with bromide paper in rolls of the size I required. They immediately consented to do so at the usual price of bromide paper. I gave the order for one dozen rolls (twenty-four exposures each, half-plate) on a Monday, and the rolls were delivered on Thursday. It is "An Extra-Rapid" quality that I have, and I have been delighted with the results I have obtained. Of course it is slow, in comparison with dry plates; about equal, in fact, to a "process" plate; but personally I prefer a slow plate.

I rarely use wax or oil on this paper, and it is perfectly suited for carbon printing (single transfer) by printing *through* the negative.—I am, yours, &c.,

ALFRED PARR.

Redditch, May 27, 1896.

MR. R. CHILD BAYLEY ON ART MATTERS.

To the EDITORS.

GENTLEMEN,—Is there a subtle conspiracy to worry photographic art and artists all along the line at a time of year when every true pictorial photographer, who would do his utmost for his art, prefers to be engaged *making pictures* instead of replying to those who try, with a kind of glorified pleasure, to prove there is nothing in pictorial photography, and, if there is, it doesn't matter? I have only recently had to help to teach a writer in a contemporary, who knows something of art, that it is possible for photographers to be artists—I hope successfully; and now I hear I am expected to reply to a reader of a paper, who, I hope, won't think I mean unkindly when I say that, if he would study the subject diligently for a few years, he may learn something about it. At present I feel that Mr. R. Child Bayley knows more about photographic chemistry, and possibly X rays, than art. I give him every credit for a knowledge of his own department, with which I never interfere or pretend to know anything. There is much that I agree with in his paper on *Photographic Societies and Photographic Art*, but also, I regretfully notice, much that is unworthy of Mr. Bayley.

As to replying to Mr. Bayley's paper, I am quite satisfied with what was said in the discussion when the paper was read at the Photographic Club (I thank Mr. Bedding and Mr. Welford especially); but I must say I agree with him particularly when he says that too many read papers on subjects of which they know little or nothing, and I greatly regret that this paper of Mr. Bayley's almost compels me to add him to the company. Nothing has ever been more definitely and unanimously acknowledged, by friends and foes all over the world (always excepting Mr. Child Bayley), than the vast improvement in pictorial photography since the institution of the "Linked Ring," and I feel hopeful about Mr. Bayley. When he grows older—I, of course, mean in knowledge—he will re-read his first crude attempt at giving his opinion on this subject, and be sorry. I have known similar cases.

Another reason for not adding to this letter is that I want to avoid saying anything to make Mr. Bayley angry, as the time is fast coming when I shall want him to "cheer up" and be a good Conventioner. I know from personal experience that he shines as a Conventioner.

H. P. ROBINSON.

CARDIFF EXHIBITION.

To the EDITORS.

GENTLEMEN,—I notice in your paper a letter signed by Mr. Freke. Mr. Freke is a friend of mine and a highly respected tradesman in the town of Cardiff. He is a picture dealer, an enterprising exhibitor of pictures by celebrated artists. He runs an artist colourman's and fancy shop, and takes photography as one branch of his business.

Mr. Freke accuses certain members of the Cardiff Photographic Society of running a studio in the Exhibition for profit. Well, Mr. Freke is also a member of the Cardiff Photographic Society, and he runs a studio in the town. I am sure I hope on the same lines which is also the case with several other esteemed members.

Mr. Freke was offered the studio, but he said it would cost a hundred pounds to build it, and 4*l.* a week for an operator besides other expenses, so as he did not see how it was going to pay, he declined to have anything to do with it. That, I may say, was the opinion of all the professional photographers in Cardiff including myself, so, very much against the grain, the individuals who obtained the concession have had to engage two professional operators and assistants, and to run the studio themselves, and we quite agree with Mr. Freke that there is nothing in it.

With regard to the letter from Mr. Horton, I, not having the pleasure of that gentleman's acquaintance resolved to interview him. I found a shop, the window filled with photographs, and a card stating the price was from 3*s.* per dozen, there was also a pole projecting from the front-door. I turned the handle, and to my astonishment found myself in a barbers' shop. I was informed by the "operator" of the scissors that the price for hair-cutting was threepence, but, on my suggesting a combined price for the hair cut and the photograph, he called down Mr. Horton, and I had the honour of an introduction to that gentleman. I may add, Mr. Horton is also a skilled musician, and used to play the flute at the local theatre; but I presume he considered that, being a photographer by profession, he had no right as an amateur to deprive a professional musician of his living, which is, of course, greatly to his credit.

13, *Wellford-road, Cardiff.* WM. BOOTH.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

Percy P. Hore, 50, High-road, Kilburn, N.W.—*Photograph of lady.*

Henry Goldsmith, Hay Cottage, Glen Aldyn, Ramsey, Isle of Man.—*Photograph of interior of Sod Cottage, thatched, near St. Indes, Andreas, Isle of Man.*

Joseph Smith, 7, George-street, Stroud, Gloucestershire.—*Two photographs of opening of new Conservative Club at Stroud, Gloucestershire, by the Right Hon. Lord George Hamilton, M.P., Her Majesty's Secretary of State for India.*

RECEIVED:—NEMO; JAS. MACPHERSON; C. KENNARD; JAS. PARKINSON; A. HOLLIDAY; "PATENT," and others. In our next.

RIVES PAPER.—J. HARRISON (Burton-on-Trent). The address of the makers is Rives, France. Messrs. Marion & Co. are the agents for it.

PATENT FOR INVENTION.—B. W. W. Registration would be of no good whatever. To secure the invention to yourself, it must be patented.

SUGGESTION.—C. MOLLOY. Thanks for the suggestion, but we think the subject would be an unsuitable one to be dealt with in our columns.

COPYRIGHT.—LANTERNIST. If the picture is copyright, it will, of course, be illegal to copy any portion of it, even the two portraits out of the several dozen.

PHOTOGRAPHIC CHEMICALS.—S. G. R. The address of the firm is Wolverhampton. We are not aware if it makes a speciality of photographic chemicals.

FERROTYPE.—F. I. We do not know, unless it is Walter Tyler, 48, Waterloo-road. If you cannot get them there, or at Fallowfield's, probably either would procure them to order.

VARNISH FOR NEGATIVES.—DAMMAR. Dammar dissolved in benzole will form a varnish that may be applied to the negative cold, and will dry transparent, but it is not a good varnish for negatives that have to be much used, as it is very easily scratched and injured. It is very suitable for glass positives, however, as they are protected by the glass.

TONING.—J. J. JONES. Collodio-chloride paper may be toned in the combined bath, but that bath is no more to be recommended for that paper than it is for gelatine papers, where permanence is an important consideration.

ASSISTANTS AND THEIR GRIEVANCES.—CELTIC. We think it preferable not to publish your letter; your case may have been, and probably was, hard, but it has little or no bearing on the subject at present being discussed in our columns.

X RAYS.—T. BELL. A coil, such as used for medical purposes, is quite useless for photographing by the X rays, even if you were to substitute a Grove battery in place of the Smee, with which it is at present fitted. It is not a question of battery, but coil, in your case.

RETOUCHING.—S. R. The retouching is very neatly done, and shows no traces of the pencil, but all modelling is destroyed. The face reminds us of the wax figures shown in hairdressers' windows rather than of a living being. For that reason we cannot pronounce it good.

THE PHOTOGRAPHIC SOCIETY'S EXHIBITION.—RITCHIE & CO. write: "Could you favour us with particulars for sending exhibits to the next Photographic Exhibition, or let us know to whom to apply for same?"—In reply: See particulars in another part of the JOURNAL.

DARK PYROGALLIC ACID.—ZERO. If the crystals of pyrogallic acid "have become quite black with age," we should say that it is of little use for developing with. However, it is a very little trouble to try it, by making up some developer with it and see the result in practice.

STUDIO AND BLINDS.—T. BLAGROVE. Either the ridge roof or "lean-to" form is preferable to the studio shown in the "B" sketch. That form of studio, though at one time advocated by some, is one that is seldom adopted by first-class photographers, except for purely copying purposes—green or dark blue blinds for the south side, and unbleached for the other.

STUDIO.—R. OSMAN. We are not at all in favour of the form of studio shown in the sketch for portraiture. The ridge roof, or "lean-to" form, is far preferable for the professional portraitist for general work. For reproduction work solely, the sketched form would be very good. From twenty-five to thirty feet long by from twelve to fifteen feet wide will be good proportions.

TONING.—PRINTER writes: "The enclosed print was toned in the tungstate bath, as recommended by Mr. John Robson about twelve months ago. I have followed the instruction exactly. Why should it be this nasty colour?"—If the bath be the ordinary tungstate bath, the print should not be that colour. Possibly, however, the paper is not one that is best suited for that bath.

PLATE BACKING.—R. SMITH. Certainly there will be a great gain in backing the plates for photographing the interiors of the greenhouses. With the majority of plates it would be impossible to get such results as would satisfy the florist without. You cannot do better than use this formula: Gum solution, 2 ounces; caramel, 2 ounces; burnt sienna, 1 ounce; methylated spirit, 5 ounces.

DISINFECTANT. FLIES IN STUDIO.—BIRMINGHAM writes: "Kindly inform me in 'Answers to Correspondents' if permanganate of potash will do for a disinfectant. Also, can you suggest a remedy to keep away house flies in studio?"—Yes; it is a good disinfectant. Flies have an objection to the smell of carbolic acid, and avoid it; so they are said to have to eucalyptus oil. Sprinkle a little of either about the floor of the studio.

BROKEN PLATES.—C. W. complains "that, upon opening two packets of half-plates, he found four out of the two dozen broken. He asks who should bear the loss, the dealer from whom he bought them or the maker, as he had the same thing happen before, and there ought to be some redress, he says?"—The makers, of course, take no responsibilities after the plates leave the works, and we should expect the dealer to decline to make any recompense.

RAIN WATER.—R. CONYER. Theoretically, rain water is as good as distilled water; but, as a matter of fact, it is, when caught from the roofs of buildings, or is collected in the neighbourhood of towns, a very impure article, and quite unadapted for photographic purposes. Ordinary tap water, or well water, is therefore far preferable to "rain water." If the ordinary supply water be boiled, it will be improved for photographic use—making solutions, &c.

CELLULOID AND ELECTRICITY.—H. O. M. O. writes: "Celluloid is said to be a highly electrical substance. Is there not a great danger with cut films, when handled, generating sufficient light to fog the films, and may not the deterioration of films from fogging be attributed to this cause?"—It is quite true that celluloid is an electrical material, but it is very unlikely that, in ordinary handling, sufficient electricity is evolved to emit light enough to fog the negatives.

STOPS FOR LENS.—M. W. R. writes: "Having purchased a 10×8 portrait lens, by Darlot, without stops, could you tell me in your next issue the diameters they should be. The focus is 13¾ of an inch."—The focus quoted, if the lens be for 10×8, is probably the back focus. It is from the equivalent focus that the stops are calculated. Find the equivalent focus, and on page 959 of the ALMANAC you will find a table and diagram giving the size of the stops according to the Photographic Society's standard.

KINETOSCOPES.—SEASIDE says: "Can you oblige me with the address of a firm supplying the kinetoscope, or a machine suitable for a show at seaside? Through my premises changing hands I am without a studio, and am anxious to get something to fill up the time usually occupied by studio work."—We think the Edison Company, Brook-street, Holborn, can supply you with what you require. Write them.

STAINS.—S. & CO. write as follows: "We are sending you a print very much stained. It has not been printed six months, and has been carefully stowed away all the time. You will see it is an ordinary P.O.P. print, toned in separate bath—sulphocyanide, &c. We have had several prints go the same way, not in batches, but one or two here and there. Can you give us any clue to this cause of fading?"—The cause is clearly due to imperfect fixing. Probably the print stuck to another or to the bottom of the dish, so that the hyposulphite did not have free action to it.

LENS FOR HAND CAMERA.—T. SIMMONDS. The most general focus lens for a quarter-plate hand camera is that of the one you have—five and a half inches. Of course, a shorter-focus one would include a greater angle of view, and one of four inches a much greater angle; but you must bear in mind that, with such a lens, the plate will not be so well covered at the edges, also that a small stop will be requisite to get anything beyond a lantern size sharp, and consequently the lens will be slower than that you have. Why not have two lenses, and only use the shorter focus one as occasion may require?

APPRENTICESHIP.—A. W. C. If you were apprenticed for three years to learn photography, you ought not to have spent two years and a half of the time in picture-frame making and mounting, and the law will give redress. As, however, you are not of age, you cannot institute proceedings. They must be taken by your mother, who paid the money. The return of that and damages may be sued for. Too many who take apprentices think more of getting the premiums and the services of the apprentices for nothing, or a merely nominal wage, than fulfilling their portion of the contract, teaching the apprentice the business.

BUSINESS WANTED.—Mad asks: "The points I want information upon are: 1. How should I set to work to find a good firm who would take me as a partner? 2. If by advertising, would the annexed be a suitable way of putting the matter, or could you suggest any improvement? 3. What would be a fair price to pay for a half share in a good concern, which would surely bring me in about 300*l.* a year as my share? 4. Would a respectable firm allow an investigation on my behalf by a solicitor or accountant?"—In reply: The advertisement as sent will, doubtless, bring replies answering Nos. 1 and 2. We do not think it can be improved on. 3. This question is rather beyond our scope. 4. Undoubtedly.

FINISHING BROMIDE ENLARGEMENTS.—J. HERBERT says: "I should be much obliged if you would kindly tell me whether it is harmful to a bromide enlargement to take out the brilliant lights with bichloride of mercury; and, if so, what is the best means of doing it? also what ought to be done to prepare the surface in order to work on the same with water colour, as I find it impossible to lay on a flat wash?"—A solution of bichloride of mercury will destroy the silver image where it is applied. We should not, however, recommend its use for the purpose suggested. A wash over with a dilute solution of ox gall, as supplied by artists' colourmen, or rubbing the surface over lightly with an ink-eraser, will, no doubt, get over the difficulty.

EMPLOYMENT IN AMERICA.—ALPHA BETA writes: "In a few weeks I am leaving England for America; can you tell me what chance I shall have out there of getting on (I am a general assistant and retoucher, but cannot operate much), the name of the paper that inserts advertisements for assistants, and its price, also the average salaries that assistants earn?"—In reply: We do not think, from inquiries made, that our correspondent will stand any better chance of securing employment in America than here at home—especially with such limited qualifications as he appears to possess. Probably the *Photographic Times* (New York) is the best paper to advertise in. Write the publishers. The average salaries are probably not higher than those paid in England; but we cannot say definitely.

FERROTYPE.—DAN OSBORNE writes: "Please help me out of my difficulty. 1. What are those white streaks on plate? 2. The cause? 3. And prevention? The plate does not become a nice creamy colour in sensitised bath. I have fused bath, but to no effect. Bath is forty-five grains to ounce. I bought collodion ready-made. 4. Is Mawson's collodion reliable? 5. Is it best to have iodiser separate? 6. Does commercial nitrate of silver require to be fused? 7. What is best book on ferrotyping?"—1, 2, 3. The "streaks" are what are known as "oyster-shell markings." One of the principal sources of the trouble is the silver solution not being thoroughly drained from the plate before it is put into the slide, and then, after contact with the corners of the carrier settling over the plate. Remedy: Drain the plates well, and put blotting-paper at the bottom of the carrier and on the corner wires, to absorb the silver solution. A newly iodised collodion is more prone to the markings than one that has been iodised a month or two. Forty-five grains to the ounce is too strong for the silver bath: thirty to thirty-five grains would be better. Possibly some of the iodide of silver was redissolved by the strong solution. 4. Yes. 5. Yes, if the collodion is bought in large quantities at a time. 6. No. 7. Fallowfield, we think, issues a work on ferrotyping.

JOURNAL OF PHOTOGRAPHY.

No. 1884. Vol. XLIII.—JUNE 12, 1896.

Contents.

EX CATHEDRÂ.

We have received an intimation from the Council of the Bristol and West of England Amateur Photographic Association that the Triennial Photographic Exhibition promoted by that body will be held in the galleries of the Academy of Arts, Queen's-road, Clifton, Bristol, from Monday, December 14, 1896, to January 23, 1897. Fuller particulars will be found in another column. We retain a vivid recollection of the magnificent Exhibition held in 1893-94, the best works of several preceding years finding place in the lofty and spacious suite of galleries the Association were fortunate enough to obtain. We have no doubt that a similar success awaits the Exhibition for which preparations are thus early afoot, and that every effort will be made to bring before the West of England a display in all respects representative of present-day photographic art.

* * *

Some weeks ago, in commenting upon a photograph of the finish of the Inter-'Varsity Boat Race that had been sent us, we remarked that, in the future, photography might supersede the distance Judge, and automatically record what is now largely matter of guesswork. The following extract from a contemporary, indicating that photography has been employed to record the appearance of a boat's crew at practice, suggests that, as we ventured to hint, the camera may yet be called in to act as an automatic judge as well as an automatic "coach":—

* * *

"The latest use of the photograph in America is to take snap-shots at Yale's Henley crew at practice for the use of the coach when too busy to leave his office at Brooklyn, seventy-five miles away from the course. These photographs, which are taken at various moments during the practice of the crews, carefully record every change or fault, no matter how insignificant. They show defects that the inexperienced would hardly expect to find in a 'Varsity crew. A few have been reproduced in the journal, and they make very interesting studies. One brawny fellow is looking at his oar, contrary to the rule 'eyes in the boat.' Another has buried his oar halfway up to the outrigger. Other photographs show one or two members of the crew too far forward or too far back, unevenness of the stroke, where a man is too slow or too fast in the 'catch,' improper method of recovery, shoulders doubled up, or one shoulder lower than the other. This novel experiment of coaching at long range is said to have proved most satisfactory in its results, for not only does the coach see the faults and suggest corrections, but the men see themselves, and, understanding the defects more fully, seldom repeat the error."

* * *

Mr. H. Piquet, of Port Talbot, forwards us an embossed photograph which is simply backed with a tin shield, thus dispensing with the use of wadding, which is commonly employed for the purpose. The metal shield prevents the photograph from losing its shape, and Mr. Piquet informs us that, in the process of mounting, there is no more trouble with the shield than without—in fact, his mounter finds less, and a better and a more even embossing is possible. The shields are made to various sizes and shapes; they will be supplied commercially.

* * *

With reference to our remarks on the suggested meeting of the Convention next year at Norwich, a friend draws our attention to the fact that, contrary to our statement, Norwich has a Photographic Society—the Norfolk and Norwich Camera Club, which, no doubt, would be pleased to assist in the arrangements if Norwich is selected for the place of meeting.

Great Yarmouth, which is about twenty miles from Norwich, has two photographic societies from which help might also be forthcoming. We gather that many local photographers are in favour of having the 1897 Convention Meeting held at Norwich, and we should be pleased to hear that a movement is to be made with a view of taking the matter into consideration.

* *

As to the Leeds meeting, we give elsewhere the official particulars of the week's programme, which will, no doubt, prove useful to many Conventioners desirous of making their arrangements well in advance. We also take the opportunity of drawing the attention of dealers and the trade to the fact that the Council will be happy to receive applications for wall or table space for the exhibition of their specialities.

* * *

THE Exhibition will be held at the rooms of the Leeds Philosophical Society, Park-row, and the Hon. Secretary of the Local Committee, Mr. Godfrey Bingley, of Thorniehurst, Headingley, Leeds, will give every information as to space at disposal, or inquiries may be addressed to Mr. R. P. Drage, Hon. Secretary and Treasurer, 95, Blenheim-crescent, London, W.

* * *

MR. ALFRED MASKELL, the Hon. Secretary of the Photographic Salon, writes: "Will you allow me to state that the Photographic Salon, 1896, will open at the Dudley Gallery on September 24, and continue open until November 7. I beg to send herewith a copy of prospectus and entry form. The regulations regarding the sending in of exhibits differ slightly from those in previous years, and we should feel obliged by your giving publicity to the same. It will be seen also that the list of the General Committee has increased in number. Entry forms will be sent out in the usual way early in August, and may be obtained also after that date on application to me at the Dudley Gallery."

* * *

THE varied nature of some photographers' businesses was brought home to us the other day when Mr. F. A. Bridge, of East Lodge, Dalston-lane, showed us some specimens of the work he has been called upon, from time to time, to execute. The well-known Universal Provider, Mr. W. Whiteley, of Westbourne-grove, possesses at Hauworth an estate devoted to the growth of fruit and vegetables; the breeding of dogs, pigs, fowls, &c.; dairy-farming; jam-making; and many other allied purposes. With his usual enterprise, Mr. Whiteley some time ago issued a handsome volume fully descriptive of his little estate, and illustrated by half-tone reproductions of over 150 photographs taken by Mr. Bridge.

* * *

ONE might say that in this collection of photographs Mr. Bridge covered almost the entire range of ground which the professional has to traverse in the course of several years. Fruit-picking, cottage architecture, animal portraiture, groups, men and women at what we may conveniently term factory labour, dark interiors, machinery, loading and unloading produce, and a score of other subjects incidental to farm work came in for treatment, all, we need scarcely say, with the most successful results. Another series embraced such prosaic objects as foundry interiors, portions of iron bridges, sewer tubes, the ruins of fires, walls more or less disintegrated, ships' saloons, and so forth. Mr. Bridge never exposes a second plate on one subject.

* * *

"THERE'S not much 'art' in such photographs," smilingly remarks Mr. Bridge, and, while we yield a partial assent to the statement, we recognise his work as admirable examples of the every-day or bread-and-butter aspects of photography. There may not be much "art" in successfully taking a difficult interior or a group of restive dogs or cattle at the first time of asking; but there is great skill, and no inconsiderable hard work. We hear so much spoken, and read so much that is written, of the importance of the art side of photography, especially by non-professional men, that it becomes positively welcome and refreshing now and then to be reminded that modern photography has its utilitarian side, in which the qualities needed for success demand a degree of application, persistence, and knowledge such as are probably not dreamed of by those who are never called upon to exercise their photographic abilities in that direction.

DAGUERREOTYPES: THEIR STABILITY AND THEIR RESTORATION.

THE interesting demonstration of the Daguerreotype at the Photographic Club recently, by Mr. Frank Haes, will not, we suspect, induce many modern photographers to essay its working, although it was mentioned incidentally that it is at the present time being worked in America.

The extreme care and precautions necessary in the manipulations, as they were pointed out by Mr. Haes as he went through them, seemed to take many by surprise. An opinion we heard expressed afterwards was that the amateur of old, who practised Daguerreotype, must have been of a very different type from the majority of modern ones, who now expect everything supplied ready for use. It is tolerably certain that few will now be likely to take up Daguerreotype, notwithstanding the beauty of the results obtainable by it and their stability.

It may appear a little anomalous to speak of the stability of a thing and its restoration in the same breath. The Daguerreotype is, however, the most permanent of all silver processes, though many examples are now in a bad state.

A Daguerreotype does not fade in the sense that a paper picture fades; the image does not fade away, but the metal plate tarnishes if the atmosphere gains access to it, in the same way that all silver goods become tarnished. It is this that obliterates the image; remove it, and the picture is as good as ever. When a Daguerreotype becomes tarnished, it will be found that the binding of the plate, matt, and glass together was imperfectly done, or that it has become loosened since, and so admitted air. It may be mentioned that this is not the first time that the restoration or cleaning of Daguerreotypes has been treated upon in these pages, yet we are continually receiving letters seeking information on the subject, also at times laments on account of accidents while attempting the work. Those who were at the Club the other night would not be surprised at this in the hands of those who are only familiar with the manipulation of gelatine plates. Although the Daguerreau image is the most permanent of all silver ones, it is, at the same time, the most tender in a mechanical sense. The least friction, even the lightest rub with the finger, is sufficient to remove the image. Lack of this

knowledge has led to many highly prized pictures being irretrievably ruined.

Here is the method of cleaning in practice. First make up a solution of cyanide of potassium, strength, say, one drachm to the ounce of water; then take the picture out of its case and clean off the paper or gold-beater's skin, with which it is, or was, secured to the matt and glass, taking care that none gets on the front. Blow off any dust that may be on the surface—the image is too delicate for a dusting brush. Now have at hand some alcohol, distilled water, a spirit lamp, and a pair of pliers. Holding the plate by one corner, flood it with spirit for a minute or two, or until it takes evenly to the metal. Then wash under the tap till all greasiness disappears. Next take some of the cyanide solution and dilute it to about eight or ten grains to the ounce, and flow evenly over the plate, keeping it rocking to and fro, and pouring it on and off, particularly *on* to those portions where the tarnish is greatest. In a very short time the tarnish will begin to disappear. If it does not, the cyanide solution must be strengthened. It is, however, better not to use a stronger solution than can be avoided. Instead of pouring the solution on the plate, a dish may be used, but we prefer the former plan, as it admits of a certain degree of local application.

When all the tarnish has been removed, the plate is well washed back and front under the tap to get rid of all traces of the cyanide. If the plate were now dried, the picture would be considerably marred by a thin veil from impurities in the water, hence it must be well rinsed with distilled water. The drying of a Daguerreotype plate is a rather important operation. If it were allowed to dry spontaneously, it would be covered with wavy marks, therefore it must be dried by heat. Light the spirit lamp and take the plate firmly with the pliers by one corner, give a final rinse with distilled water, and drain off at another. From this time the position of the plate must not be changed until it is dry. Now bring the top corner of the plate—that diagonally opposite the one from which the water was drained—just above the flame of the lamp, and, as it dries, gradually bring more of the plate over it, so that the drying proceeds uniformly from the top downward. If the drying be checked at any point, a mark will be the result. The picture should now be replaced in its case without delay. The plate must be bound round with paper or gold-beater's skin to the mat and glass so as to make it perfectly airtight, and starch or flour paste is preferable to gum for the purpose of an adhesive, as the latter is prone to split from the metal if it becomes very dry.

The object of the treatment with the spirit is to cause the cyanide to take evenly, as some Daguerreotypes are very repellent and then stains might arise. If the picture were well gilded in the first instance, it will now be restored to its original beauty, and will, if perfectly protected from the air, last, practically, for ever. So indeed it would have done if it had been properly secured when it was first produced. It will be seen that the restoration of Daguerreotypes is a very simple affair. Simple though it seems, it requires some judgment, and we should not advise any one to make his first attempt on a highly prized portrait. Rather than do that, it would be better to intrust the work to an expert, or to get one or two valueless ones to experiment upon. In any case it will be better for the novice to make a copy of the picture before cleaning it, so as to be able to fall back upon that in case of any accident to the original.

Illegal Use of the Royal Arms.—A case of some interest to those photographers, as we believe there are several, who use the Royal Arms without the authority to do so, was heard at the Marylebone Police-court a week or so back. Four West-end tradesmen—a carver and gilder, a milliner, a stationer, and a baker—were proceeded against for having, without authority, assumed and used in connexion with their business the Royal Arms, or arms so nearly resembling the same as to be calculated to deceive and lead to the belief that the businesses were carried on under Royal authority. The prosecution was instituted by the Incorporated Association of Her Majesty's Warrant-holders. This Association, it may be mentioned, is a number of tradesmen, who have the Royal warrants, banded together to protect themselves against persons illegally using the Royal Arms. The prosecution did not press for the full penalty, which is twenty pounds, but for a nominal one, as an undertaking that the use of the arms would be discontinued. Upon the defendants giving this undertaking, they were each fined the mitigated penalty of forty shillings and costs.

The defendants pleaded ignorance of the law, but the magistrate (Mr. Plowden) said that he should have thought it common knowledge that permission had to be obtained before a tradesman could use Royal Arms. We have little doubt but that several photographers who are using the Royal Arms are doing so quite in ignorance that they are breaking the law. Hence our giving prominence to this prosecution. Some we know are under the impression that, if they have supplied anything to her Majesty, or may have executed an order for her, they have forthwith the right of putting up the Royal Arms. Such, however, is not the case. No one is entitled to use the Royal Arms without a special warrant to do so under a penalty of twenty pounds.

It may not be known to every one that it is illegal to use the terms "Patent," "Patented," "Registered," or such terms as would imply that the article was patented or registered when it is not. The penalty in this case is, on summary conviction, five pounds. We merely mention this, as we often see on photographs the work "copyright," although we have known there was no copyright in the work.

A Caution to English Tourists Abroad. — Three English cyclists, with hand cameras, found themselves in an awkward dilemma last week in France. While at Stenay, the Sixth Army Corps were under review, and they took some snap-shots of it without being aware that they were doing anything wrong. However, they were quickly arrested, and they were detained during the whole of the time the review lasted, and then subjected to a severe verbal examination. Finally, they were liberated, but not before the general staff had departed. This incident should serve as a caution to English photographic tourists in France as to the indiscreet use of their cameras. Things are different on the Continent from what they are here. A hand camera, we suspect, would not be objected to at any of our military displays.

The above incident, occurring just at the opening of the touring season, leads us once more to suggest that English tourists, with cameras, on the Continent should provide themselves with passports before starting, although they may not be required by law in the countries in which they travel. Any one not knowing the laws and regulations of a country may innocently transgress, as in the case of the three Englishmen just cited, and the possession of an English passport is usually, on the Continent, taken as a guarantee of the owner's *bona fides*, and thus helps him out of the difficulty. A passport is obtained without trouble, and its cost is but nominal. It will do for all countries, and will serve for all time. To be "run in" in a foreign country, while on pleasure bent, from an innocent cause, even for a few hours, is not pleasant; and, although the passport will not avoid the arrest, it will generally hasten the release.

Picture Exhibitions.—The picture season is now "full on," and each season seems to bring forth more exhibitions than the previous one. A glance down the advertisement columns of the *Times*, or any of the leading papers, will give evidence of this. Fine Art Exhibitions, at this season, are not confined to England, as there are at the present time similar shows in all the principal Continental cities. On Monday, last week, the Annual International Art Exhibition at Munich was opened at the Glass Palace by the Prince Regent. The Bavarian capital has always been an art centre, and its annual exhibition generally includes some of the best works of the leading artists of all nations, England usually being well represented. This year there are some thirteen hundred works shown, and we learn, from private sources, that the Exhibition is quite up to, if not beyond, the average, and that means a good deal in Munich.

An Amateur's Business Matter.—On the occasion of the Croydon Camera Club's visit to the new municipal buildings recently opened by H.R.H. the Prince of Wales, at the invitation of the Mayor, the President, Mr. Maclean, drew attention to the fact that the proprietor of a local paper had specially invited *amateurs* to submit photographs of the Royal visit for publication. He explained that the trade custom was not to accept less than 10*s.* 6*d.* for each print, and urged the members of the Club not to undersell each other or spoil the market by offering prints for less than the standard minimum. The report says that these remarks were well received by those present. It is to be hoped that none have let their pictures be used for any less sum than that mentioned, thereby underselling the professional photographers. Some illustrated papers just now are very anxious for amateurs' work, thinking, no doubt, that they will save the fees charged by the professional, and we are pleased to see that all amateurs do not swallow the bait.

The Spitzbergen Expedition.—This Expedition, under Sir Martin Conway, is now on its way, having left Hull on Tuesday last week. A well-known member of the Alpine Club, who is a geologist and a good photographer, forms one of the party. As this Expedition will not proceed to the extreme northern regions, and will only remain during the summer months, the plates taken are not likely to be exposed to long-continued extreme cold, as in the case of other Northern expeditions. It would be interesting to know how gelatine plates will behave after being subjected to abnormal cold for a lengthened period, and then exposed under similar conditions of extreme cold. None of the Arctic expeditions have supplied reliable information on this subject up to the present.

Photographing Stars with a Small Telescope without a Driving Clock.—Many amateur photographers with a knowledge of astronomy have been debarred from joining their two hobbies through not being able to incur the expense of the driving clock, usually considered a necessity for the work, but in a recent number of *Nature** Mr. Joseph Lunt has a valuable article showing how to perform much interesting and useful work with no special apparatus whatever—no clock, no driving machinery, not even a tangent screw and slow-motion rod. He very rightly observes that "when amateurs come to recognise that, with their small instruments, such a fruitful field of investigation is open to them, astronomy will probably be enriched by many discoveries which would otherwise be missed or delayed." He gives in the article referred to an illustration of the home-made apparatus employed. His telescope is three and a half inches, mounted on a firm equatorial stand, supported on a home-made brick pillar. It is mounted on a home-made wooden tube of square section, and on the opposite side of the axis is a second telescope, used as a finder. Attached is also a small finder, and, in addition, a fourth optical arrangement, neither more nor less than a small camera, with a two-and-a-quarter-inch portrait lens. The latter is used for obtaining duplicate photographs on a small scale simultaneously with the larger. "As regards the actual driving of the apparatus, very little power is required, as gentle pressure of the finger at the lower end of the baseboard carrying the objective and the plate is sufficient to move the telescope at the proper rate, and the co-operation of hand and eye during finding seems soon to become almost automatic in character." Good and useful star charts can be obtained, Mr. Lunt states, by means of the photographic camera alone, and without any motion, about fifteen seconds' exposure giving good results, the stars, of course, showing as trails instead of dots. To use the finding telescope, the image of a star much out of focus was observed, the eye being kept constantly at the telescope, so as to keep the image constantly in the centre of the crossed lines. As the size of instruments indicated are not larger than those possessed by many an amateur observer, it is to be hoped that Mr. Lunt's method may be the means of increased pleasure and usefulness to many an amateur photographer and astronomer.

* *Nature*, No. 1387, October 4, p. 85, *et seq.*

Eclipse Preparations.—As the time of the August eclipse approaches, it is rendered evident that observations will be made by astronomers from all quarters of the globe. From this country the observers will mostly proceed to Norway, but Mr. Maunder and some American astronomers have selected Japan, and have already sailed *en route* for that country. Unfortunately, from statistics furnished by the Japanese Ministers, the prospects for fine weather are distinctly bad. For the last five years, the average gives for the month of August—cloudy days, 22; rain or snow on 22 days; clear days, 0! Mr. Norman Lockyer desires to erect his station on the south side of Varanger Fjord if possible, and, to ascertain whether it will be available, Captain King will be detached from the Squadron to investigate. The eclipse will be visible from many parts of Russia, and the various societies and learned bodies will send representatives to Nova Zembla, Olenkminsk, the Mourman coast, and Uleaborg in Finland.

The High Price of Camphor and Photography.—There would seem to be no connexion between the gradually increasing price of camphor and the pursuit of this favourite science; but Professor Abel, after having shown that the notion that the use of camphor in smokeless powder has caused such demand as to increase the price is entirely fallacious, points out that, in all probability, the cause is owing to the large use made of camphor in the production of celluloid, so largely used of late in lieu of glass for photographic and other purposes.

Röntgen Sciography.—Steady work is now being carried on by scientific men in investigating the cause and actual character of the rays; but they seem to be as far off as ever from arriving at a decision. The theory at one time advanced, and afterwards mostly rejected, that they are a form of ultra-violet rays seems again to be attracting more attention and receiving support. Professor Hartley gives four points in common between the ultra-violet and the Röntgen rays. Attempts have been made to polarise them; but, though there is some little doubt as to the bearing of the experiments, they seem, on the whole, to indicate non-polarisation. Mr. T. C. Porter of Eton College, has been endeavouring to analyse them, and finds himself able to divide the radiations into two qualities which he provisionally terms X_1 and X_2, the former possessing the usual character, and the latter being quite different; able, for example to pass through metal, the type of ray possibly which is able to pass through the metal screens and produce photographs of the solar corona in daylight, as described by Mr. Packer. At the University Extension College, Reading, Mr. George J. Birch in conjunction with his colleagues, has been utilising the Röntgen rays for exhibiting the details of plant structure, and has obtained most interesting results, for example, the ovules inside an unopened bud, the seeds within a seed vessel, and even the veins in the petals of a white flower have been photographed.

The Queen of Portugal and the X Rays.—Queen Amélie has turned an investigation on the rays to a novel and praiseworthy purpose. She has been taking sciographs of the trunks of various Court ladies, exhibiting them to the subjects of the experiment with the purpose of demonstrating the evils of tight-lacing. This is truly bringing in science to bear on humanitarian objects.

BY THE WAY.

As I sit down to write, the weather is that of late summer or early autumn, instead of mid spring, and both light and temperature remind one of August rather than the early days of June. The "photographic campaign," as it was wont to be called, has fairly opened; and, with a fine Whitsun Bank Holiday just passed, it may be predicted with certainty that a large number of successful pictures have been already secured by the vast army of photographers who probably make that their opening day. Not that nowadays time and season matter much in photography, modern plates being quick enough to work as well in mid winter as in the height of summer, rain and fog being the only enemies the outdoor worker has to fear.

I was forcibly reminded of the immense difference that exists between the conditions now prevailing and those of twenty years ago on turning over a portfolio of miscellaneous photographs a few days ago. I had been making exposures of a fraction of a second on "ordinary" plates, the subjects being landscapes clothed in spring foliage, and, if anything, I could have done with a smaller stop or a shorter time. I came across an old photograph by a distinguished American amateur of days gone by, and still happily alive, Dr. Ellerslie Wallace, that brought vividly to my mind the difference I have referred to. The subject was a street scene in one of the old-time Continental towns, an albumen print that shows all the vigour and brilliancy for which the best work of twenty years ago was notable, combined with the delicacy and fulness of detail that is supposed to be the special feature of modern gelatine plates. From the particulars noted on the back of the mount I gathered that the picture was taken in July 1877, on a Fothergill plate, with a Ross seven-inch portable symmetrical lens, stop *f*-20, and an exposure of six and a half minutes! Think of that, ye modern "snap-shotters," and try to realise the difference in time only involved in the production of a dozen negatives, and the possible size of an afternoon's "bag" then as compared with now.

But the difference is by no means confined to the time question, more especially in the class of subject I have mentioned, or, indeed, in any kind of picture round about the usual holiday resorts. With an exposure of a part of a second, or even a few seconds, the photographer is comparatively independent of human interference, intentional or otherwise, if he lay his plans with ordinary circumspection; but think of the crowd of curious spectators and mischievous *gamins* that would collect together round the camera in six minutes, to say nothing of the unwitting interference of innocent passers-by! As an old worker of dry plates in days when exposures were reckoned in minutes instead of tenths of a second, I have painful recollections of many a half hour or longer spent in giving disjointed exposures which, when complete, perhaps only totalled up to two or three minutes; and only those who have experienced it can realise the intense pleasure that is to be derived from the badinage and "chaff," if nothing worse, of a half-hour's contest with an unruly crowd, who all wish to occupy the best, and, to the photographer, perhaps, most awkward positions in the picture.

But the culminating point of agony and wrath combined was reached once when photographing one of the prettiest of the numerous waterfalls in the English Lake district. All was quiet when I arrived on the spot, and every condition of light and freedom from wind was in my favour, and I anticipated nothing but a "good time." I had leisurely selected my point of view, and focussed to my satisfaction, when, on emerging from beneath the "velvet pall," to my horror, I noticed a crowd of people climbing down the rocks, and remembered that there was a "cheap trip" that day from one of the northern manufacturing towns. I was working at the time some, for the period, pretty quick plates, and hoped to get through with my exposure before the interruption of the crowd reached me; so I got my plate into position, and uncapped the lens with all celerity; but fate, in the shape of a sharp breeze, was against me, and I was compelled to cap the lens and wait for stillness, and before that came the enemy was upon me.

Not only upon me, but above, below, and all round me, and lunch baskets, bundles of sandwiches, and ginger-beer bottles figured in prominent positions on every coign of advantage. Polite requests for a clear view for only two or three minutes were utterly unavailing, and expostulation only led to vituperation of a kind that only the Lancashire factory operative can equal, and, as I was only one against thirty or forty, I had to content myself with patiently waiting until it should please my tormentors to take themselves off. For upwards of an hour and a half I stood by the camera to protect it from any accident that might chance to it from their horse play. One lout actually slid from a height down the rocks to within a foot or two of the tripod, and I must admit that it was with feelings not altogether akin to sorrow that I saw him picked up, bruised and shaken, and carried or led away by his companions. At intervals, when the coast was clear, I managed to get in a few seconds' exposure, and eventually, when it became necessary that they should retire in a hurry to catch the train, I accepted their final abuse with equanimity and even pleasure, and proceeded to finish my exposure with a feeling of satisfaction and a metaphorical "patting on the back" for my patience, that were eminently soothing; but this feeling was changed to the bitterest gall when I discovered that I had forgotten in my hurry to draw the shutter, and it was too late to commence afresh!

Then, again, from an artistic, or, rather let me say, from a *pictorial* aspect, how things have changed! I remember on another occasion in the Lake district, at the close of a summer afternoon, gazing on a scene that, if I could have transferred it to my plate, would have created a "sensation" in Pall Mall. I was standing on a promontory jutting out into Windermere Lake, with the ranges of hills behind Ambleside filling up the background, and the rapidly setting sun throwing long shadows of Belle Isle across the water in mid distance, while in the foreground a group of cattle, knee-deep in the margin of the lake cooling themselves after the heat of the day, completed a picture that would have been hard to beat. I had a plate left; but, if it had been midday instead of nearly sunset, it would have required at the very least a minute's exposure with the largest aperture I dare use; as it was, probably an hour would have been insufficient, so sadly did the dry plates of that day fall off in sensitiveness late in the day, so I was compelled to bear away the picture in memory only, instead of in more tangible form, where to-day I could have secured it easily, only, however, to take its place amongst others as a very ordinary piece of work.

That was some thirty years ago, but let us look back to a much later date—the early days of gelatine plates—and compare the work then with that of now. Probably many of my readers will remember, to select one example hap-hazard, Colonel Gale's picture of *Brixham Trawlers*, one of the "gems" of the Exhibition of 1879 or 1880. Simple in the extreme, a group of fishing boats exquisitely rendered, with the faint ripple on the almost still water, and the delicate haze or atmosphere of early morn or late afternoon—how it took popular fancy as a foretaste of the capabilities of the then "new" plates! but, now, probably, it would be passed over as a pretty picture, without doubt, but nothing out of the common.

Similarly, many will remember the famous *Swallow* picture of the same artist, and the sensation it caused, as well as the sharp controversy as to its genuineness as a pure photograph, the truth on that point having never yet, I believe, been authoritatively settled. Here was a picturesque pool of water, surrounded by trees, through which the sun glinted, causing a bright reflection in the centre of the pool, over which poised, "dipping his wing," was a swallow, so sharply defined that the markings of his feathers were clearly seen with a magnifier. Cruel critics, indeed, went so far as to say they could distinguish something put in by the "stuffer" to represent its eye; but, be that as it may, whether a live or a stuffed bird, it was so happily placed as to make a veritable picture, and was the admired of all visitors, and *the* picture of the show. If a similar picture of undoubted genuineness were produced at the present day, it would be accepted without surprise as a clever *coup-de-main*, rather than as a photographic achievement; its artistic merits might be undeniable, it would take rank as a *picture*, but would no more raise any question as to its method of production than if it were a painting.

Yet, with all our improved facilities in working, I question very much whether, at the present day, as good work proportionately is

done as was done twenty, or even thirty, years ago. Mind, I do not mean to say that, at the present time, there is not a far larger bulk of really good work done than was done in the old days, for that would be simply absurd; but, taking into account the possibilities of modern plates and the immensely larger number of workers using them, there is a far smaller proportion of pictures produced that can be classed as out of the common than was formerly the case. Take, for instance, from a purely scientific point of view, the historic picture by Fox Talbot, taken at the Royal Institution by means of the electric spark, of some printed matter attached to the periphery of a rapidly revolving wheel. With the sensitive, or rather insensitive, films of that day, this was a really wonderful achievement, as may also be said of the "instantaneous" pictures, some of which still exist, taken upon Daguerreotype plates forty or fifty years ago. Then, on the artistic side, reverting to Colonel Gale's *Brixham Trawlers*, at the time that picture appeared I had in my possession still—but they have now gone the way of too many albumen prints—some stereoscopic pictures of similar subjects which took a prize for "instantaneous" work given by the Amateur Photographic Association in the early "sixties." These consisted of sailing barges *Off Grays*, and, except in delicacy of definition, having evidently been taken with a very wide apertnre, were almost as perfect as the more modern productions.

I have just alluded to the way of too many albumen prints of fading, but I am far from being of opinion that it is an invariable or a necessary way. The picture I referred to in the early part of this article, by Dr. Ellerslie Wallace, was produced long before the days of gelatino-chloride, and has been in my possession at least fifteen or sixteen years. I cannot say the exact date I had it, and, though the mount has become dirty and *yellow*, the print itself is as rich in tone and as pure in the whites as if it had only been done yesterday. Some unmounted prints by the same artist—and I use the term in its fullest sense, given to me by himself on the occasion of one of his visits to this country in 1876 or 1877—were in an equally good state of preservation the last time I saw them, two or three years ago, in the album of a lady friend, who fell so deeply in love with them that I was reluctantly compelled to let her "annex" them. For which reasons—and many others of a similar character might be cited—I do not think that albumen prints are necessarily more fugitive than any others. It has been said that albumen prints *must* fade from their very nature, which I, for one, think absurd. On the other hand, it has been said, with more apparent truth, that, if an albumen print will keep for twenty years, or even for ten, there is no reason why it should not keep indefinitely.

The truth is, more depends upon the worker than upon the paper, and the reason why poor albumen has got such a bad name of late years is that the working standard is not as high as it used to be, or, in other words, the tendency to carelessness is greater. This, combined with the introduction of cheap and nasty papers, will, no doubt, account for the bad repute of an article that, if properly used, will answer the requirements of permanence, as has been proved beyond doubt for periods of twenty, five-and-twenty, and thirty years; and, if such periods as these, why not longer?

It is not with any intention of posing as *laudator temporis acti* that I speak of the lowering of the working standard. On the contrary, I believe that at the present day there are workers quite as careful as those of twenty and thirty years back, who possess, moreover, the additional advantage of a wider scientific knowledge of the processes and materials they use than was possible at the earlier period; but it is equally true that there are, in the ranks of photography, a vast number of workers to whom the scientific or technical side is but a nuisance and a bugbear, who follow photography simply for the sake of its pictorial results, and who only go through the mechanical part of the business if they do it themselves, because it is necessary to the end they have in view. It is chiefly these who bring discredit upon photography as a means of permanent record, not perhaps from inherent carelessness, but rather from insufficient knowledge. I know two or three of the class who are notable for their fastidious care and "finicking" ways in everything they undertake, but who make horrible messes of things generally in photography because they will not go deeply enough into its "drudgery."

The fact is, the whole face of photography has changed of late years. The best-known amateurs are those whose names are known through the prize-list, with a small scattering of scientists. The best known professionals are those who make our plates and papers, while the old "professional," the portrait photographer, keeps himself pretty much to himself. In former days it was the professional who talked "art" and picture making before the societies and who took most of the prizes, while it was the amateur who talked—"shop," I was going to say, or processes and formulæ; but we have changed most of that, and, as time wears on, no doubt the difference will be wider still.

Before closing this, I cannot help going back to a subject that has occupied a good deal of my previous contributions—carbon printing without transfer—but only to pass on a suggestion made by a friend of my own. It is this, that those who desire to avail themselves of the simplicity of the bichromated gum, or other non-transfer process, have only to procure a Levy screen and make "half-tone" negatives, which, if the ruling be fine enough, will entirely get over any difficulty in the matter of half-tone or gradation. A "half-tone" negative from a hard positive possessing over-strong contrasts can be made to yield a print of any degree of softness and delicacy on silver paper, if not carried to the degree of density required for etching, and without showing nearly so much grain as the etching would; and such a negative would be very suitable for carbon printing without transfer. Until it becomes feasible to produce such plates direct in the camera, there would, of course, be the necessity for reproduction.

"Clonmel" asks me a question or questions *re* bichromated albumen paper. I think his difficulties arise solely from not floating the paper long enough for the solution to penetrate to the albumen, which it will not do in *two minutes*, and from over-exposure.

DOGBERRY.

NOTES ON RADIOGRAPHY.

At so early a date in the investigation of a series of phenomena, which will require years of research before any definite and conclusive results can be arrived at, I should feel great diffidence in addressing your readers were it not for the fact that so many misleading and inaccurate statements are daily put forward by the lay and scientific press.

In a paragraph of your issue of May 8, referring to some experiments made by M. G. de Metz, appears the following sentence: "He finds that the cathode rays possess one of the properties of the Röntgen rays, in that they penetrate aluminium, cardboard, and paper, but are stopped by platinum and copper." Some two months back I stated in public that, in my opinion, no substance is opaque (in the ordinary meaning of the word) to the so-called X rays, granting that a sufficiently lengthy exposure be given. At the present time, after numerous experiments, I see no reason to withdraw this statement; on the other hand, increased experience only serves to emphasise the fact. Whether or not the cathode rays pass through platinum and copper, I am unable personally to make a positive statement, but I am of opinion that they do not; but that the X rays do pass through these metals I am certain, and by way of proof I enclose a radiograph through eight metals, among which are platinum and copper. The negative from which this print was made was produced upon a Thomas's cathodal plate, with an exposure of five minutes, at six inches from a focus tube, made for me by Mr. Cossor, an eleven and a half inch spark being used.

I have succeeded, under the same conditions, in radiographing a sixpence through seven thicknesses of pen-steel, through five thicknesses of hard-rolled copper, and through eight layers of ferrotype plate. With ten minutes' exposure, at the same distance from the tube, I obtained radiographs through ten layers of pen-steel and seven of sheet-lead.

In an interesting article, *On the Progress in the New Radiation*, by Mr. A. W. Isenthal, in a recent issue, when speaking about the focus tube, the following statement is made: "The solid in the focus is mostly a plane piece of platinum, as it will allow no X rays to pass through, it being very opaque to them, but will reflect

them and send them all outwards on to the object to be radiographed." I have already shown that platinum is not opaque to the X rays, and, moreover, have failed to produce evidence of their being reflected by this metal.

My experiments lead me to the conclusion that the term "focus," as applied to this special form of tube, is not the right one. In the first place, we have not yet positive evidence that the X rays start within the tube; hence it is premature to surmise that platinum reflects these rays within the tube while it fails to do so outside.

That platinum stops the cathode rays has been demonstrated by Mr. Crookes, and, granting that it is a fact that the X rays start from the surface of the glass struck by the cathode rays, is it not probable that the metal, by confining these rays to a small portion of the tube, limits the area from which the X rays emanate?

As it is for various reasons impossible for me to manufacture and experiment with new forms of tubes, I make this suggestion, in the hope that some investigator who has facilities for so doing may use his endeavours in throwing light upon this most important question. A few days since an investigator published a list of substances which he states are opaque to the X rays. The enclosed radiograph clearly proves that four of the substances, viz., steel, copper, platinum, and nickel, are anything but opaque, and I have no hesitation in saying that the rays will pass through every one of them. The results here shown do not give the comparative transparencies of the metals experimented with, for the simple reason that there is very great difficulty in obtaining sheets of various metals of the same thickness; they are, however, as nearly alike as I can at present obtain them, and are sufficiently so to prove, at any rate, that they are not opaque.

My reason for burdening your readers is to draw their attention to the fact that they must not accept as gospel truth any and every statement which is set forth, even in the scientific journals.

HALL-EDWARDS, L.R.C.P., F.R.P.S.

P.S.—The rings in the enclosed radiograph are of brass, one-twentieth of an inch in thickness. They are placed upon the sheets of metal in order to show their transparency, as they could not be seen unless the X rays had passed through the metal.

1. Hard-rolled copper.
2. Platinum.
3. Steel.
4. Nickel.
5. Zinc.
6. Strips of aluminium.
7. Sheet lead.
8. } Brass brace buttons. These are interesting, as they show the
9. } differences of thickness.

[Dr. Hall-Edwards's radiograph lies at our office for the inspection of those interested.—EDS.]

A COMPARISON OF ORTHOCHROMATIC WITH ORDINARY PLATES.

I.

So much admirable information upon the subject of this paper has lately been forthcoming, that some explanation is due to my readers for adding this contribution to the already large mass of matter that has been recently published.

That I do so is because, in the first place, Mr. G. R. White, about the beginning of the year, gave an exhaustive address to the members of the Croydon Camera Club, in the course of which he was reported as making certain statements which were hotly challenged by several well-known writers upon photographic matters. Secondly, circumstances have ever since prevented Mr. White from recapitulating, with the necessary fulness and precision, what was the staple of his remarks on the occasion in question. He has therefore placed in my hands his notes and illustrations, and has further submitted himself to my cross-examination, so that I might be in a position to place before the photographic world what are the main conclusions at which he has arrived after careful and independent study and experiment.

I need hardly remind the average reader that what is termed *orthochromatic rendering* of colours in equivalent tone values is a subject which, *ab initio*, bristles with difficulty. To begin with, the comparative brightness of one colour to another is not by any means a constant value, but varies almost indefinitely, according to the individual colour-sensitiveness of the eye. Thus, in *extreme* cases, a full orange, but well-lit, cloud, standing out from a deep blue sky, may, to some eyes, seem as a dark against a light, which, although quite the reverse of how it strikes the average eye, is very much what a bad photograph might render. Besides this disturbing influence, due to the variable effect of different colours on different eyes, we are at the very threshold of any comparative test between makes of plates or systems of screening, &c., confronted with the difficulty of finding a *constant standard* of comparison which, with approximate accuracy, includes the conditions of lighting met with in ordinary practice.

Ever since the subject has been seized upon by the laboratory investigator, practical photographers have felt that, however true the conclusions drawn from particular series of experiments held under artificial conditions might be, the results did not of necessity affect practical photography; for, to commence with, the colours mainly relied upon have been what may be termed *pure* primaries, secondaries, or, more rarely, tertiaries. By pure I mean as pure as ordinary pigments make possible; but in every-day practice we never meet with pure colour. A cursory examination of almost any object will reveal that its colour is a very complex combination, capable of resolution into blue, red, and yellow; any how, the occasion will be rare indeed where an object does not contain a considerable proportion of latent actinic power due to this colour mixture; apart from which we have to consider the important bearing of reflected white light, *i.e.*, rays which fall upon the surface at such an angle as to escape selective absorption.

Place a *smooth, ruby-red* covered book on a table between yourself and the window, so that it lies about eighteen inches below the eye; at a certain distance, easily found by experiment, the cover will seem almost white, and, if photographed from the position in question, the resulting negative *might* be made to print the book cover as quite white, this notwithstanding that its colour is of the *most non-actinic* deep ruby red. On the other hand, if the surface were rougher, the normal effect would become, *pari passu*, less.

From these experiments it might, at first sight, be assumed that only smooth objects reflect any considerable amount of white, or almost white, light. The truth of the matter, however, is that where a surface is broken up, either by its main contours, or by the irregularity of its surface texture, the variously inclined planes thus presented so deflect the white-light rays that, although just as many may be surface-deflected, they do not assert themselves in any one particular direction, but are given off as scattered light.

Thus the total amount of white light emitted by a non-actinically coloured illuminated object may be not a whit less than in the case of the red book cover referred to above; but, instead of the object being partially illuminated by such white reflected light, the whole surface gives off a somewhat regular proportion of actinic rays, which are perfectly independent of the local colour.

Now, in copying coloured diagrams or charts, *special* arrangements are made, by means of side-lighting, &c., to, as far as may be, entirely eliminate the above "surface reflections," thereby falsifying the natural conditions which, except in copying pictures, &c., prevail.

It should also be remembered that the printed or painted pigment colour charts, although in some respects better than the spectroscopic tests, are so prepared that the results must necessarily be liable to mislead, for, without entering into technicalities of painting by means of stippling, glazing, hatching, and other resources, the difference between visual and photographic values may be very considerably varied; for all which Mr. White has illustrated his arguments mainly by means of photography of a colour chart which he has prepared for the occasion. This because one cannot well speak about the colour-rendering of a scene which is not before the eyes of an audience.

One merit the screen possesses is that it differs in its preparations from others.

To my mind the chief value of what Mr. White advances is that his testimony, as far as I can find out, is perfectly free from bias, and is that of a photographer who has been in active and varied practice for over ten years, during a considerable proportion of which time he, as Hon. Secretary of the Croydon Camera Club, has enjoyed the opportunity of comparing results obtained by members, some of whom being well-known experts in practical technique.

Partisanship, either for or against specially sensitised plates, is, no doubt, a great help to the cause of correct colour-rendering, inasmuch as the extremists on both sides give each other's arguments no quarter, and thus aid in establishing the real truth. Meanwhile the ordinary photographer, who does not want to wait until the wordy fray is done, will be, I feel sure, glad to hear what are the results of an independent examination of the question by one who has no axe to grind.

HECTOR MACLEAN, F.R.P.S.

THE SOLARISATION OF DRY PLATES.

[Photographisches Archiv.]

Examine from the back a number of finished negatives taken on dry plates. When the plate is held against a black background, a positive image may be seen on some, whilst on others this is not the case.

Although both classes of negatives have a corresponding black appearance when examined from the front, the former have a white colouration on the glass side, whilst the latter, in corresponding parts, are black.

This whiteness is due to a remnant of bromide of silver, which is left unchanged during fixation, and it is held between the reduced silver and the glass.

Negatives retaining bromide of silver are those that have been fully exposed. In under-exposed plates it is absent. It is only visible in the high lights in correct exposure, as, for instance, in the sky of a landscape.

In those parts of the plate fixation is not complete, and, if even more time had been given for the action of the hyposulphite of soda, the bromide of silver would not have been removed. This appearance is quite as marked in negatives developed with hydroquinone and amidol, as in those with pyrogallic acid, Consequently it does not arise from the tanning of the gelatine.

In the *Photographisches Archiv*, 1896, p. 10, I have drawn attention to the fact, that a dry plate upon which a metallic veil has been formed during development fixes very badly. It always contains a remnant of bromide of silver. Only when the red fog has been removed by means of bromide of copper can the elimination be completed with hyposulphite of soda. The fixation is therefore hindered in fogged plates by the thin film of silver. It is very probable that the appearance to which we now draw attention has the same cause, that is to say, that the silver reduced by light and the developer does not permit the hyposulphite of soda to force itself through. This explanation is supported by the fact, that at the juncture of a very dark with a light part of the negative the bromide of silver is removed in fixing for the breadth of about a millimetre round the dark part. Consequently the positive seen from the back of the plate is smaller than the negative. The hyposulphite of soda in those parts has not penetrated from above, but sideways. (See also, in comparison, the remarks on the lines noticeable at the margin of exposed and unexposed images.—*Photographisches Archiv*, 1895, p. 158.)

The observation that, under the circumstances referred to, bromide of silver may be left in a negative, is of itself of no great importance. It, nevertheless, increases our knowledge of the composition of the finished negative, and we must remember that it contains not only silver, gelatine, and oxidised products of the developer (see *Photographisches Archiv*, 1895, p. 174), but also unreduced silver salts. But much more important are the conclusions to be drawn therefrom for the physics of development.

If bromide of silver is left behind amongst the silver, the former cannot have been reduced by the developer, and the picture does not always extend from the surface to the glass. And especially is this the case in the highest lights, where it might be most expected.

It is therefore certain that the developer also has not penetrated to this depth in the high lights, and therein resembles the hyposulphite of soda. With a shorter exposure, on the contrary, it penetrates the entire film and reduces the bromide of silver through to the glass.

In this way a phenomenon can be accounted for, in explanation of which purely chemical causes have usually been accepted, viz., the solarisation of dry plates.

If part of a plate is very considerably over-exposed, the reduction is confined to the mere surface in that part. The film of metallic silver formed there is extremely thin, but it hinders completely the further penetration of the developer.

The reduction on the surface is too rapid at that part, but at the others, where the exposure is less, the reduction occurs more slowly, and meanwhile there is time for the developer to penetrate to the underlying portions. The latter consequently are stronger, and contain no bromide of silver.

The rapidity of reduction is the all-important thing. It is not necessary to assume, as I at first thought, that with longer exposure a coherent skin of silver, whilst, on the contrary, with shorter exposure, one richer in pores, is formed.

With over-exposed plates, a strong developer gives flatter pictures than a weak one. For this reason we find a very weak developer in a dipping bath so valuable in such cases. An addition of bromide of potassium slows development, and consequently gives denser images. But there is also the possible explanation, that the bromide of potassium renders the surface less amenable to development, and, by a consequent slower formation of the film of silver, permits a deeper penetration of the developer. The increase of the solarisation by an addition of hyposulphite of soda, thiosinamine, or much ammonia, is referable to the reverse process.

It is impossible to prove or to controvert this theory of solarisation, in the development of dry plates, by experiment, either by exposure through the back or by stripping the gelatine film from the glass before development. In the first case, the protecting film of silver is still formed on the surface through over-exposure, because the light has penetrated from back to front. The remaining bromide of silver is clearly visible from the back of the plate after fixation. If the film is stripped, the protecting layer is formed on both sides during development, and encloses the bromide of silver (or perhaps, more correctly, sub-bromide of silver).

If a negative is examined from the back during development, sometimes the image is invisible, but sometimes a negative, and at others a positive, can be seen. The image at the back is different with different kinds of plates. Gelatino-chloride plates give an image through the back much more quickly than the very rapid bromide plates. This difference depends partly upon the greater penetration of the active rays through the fine grain of the chloride than the coarse grain of the bromide.

But I will not enter further upon the causes of these differences, and will only describe what may be seen with one description of plate, a gelatino-bromide plate of ordinary sensitiveness. These observations, however, give very important support to my new theory of solarisation.

A normally exposed plate, after a certain time, shows a negative through the glass. (For shortness, I will use the expression, Negative penetration.) This negative grows more intense as development proceeds.

An under-exposed plate also shows negative penetration, especially if so much light has passed through that a blackening is perceptible from the glass side. Otherwise it remains uncoloured.

A much over-exposed plate, after prolonged development, shows strong positive penetration. Sometimes this positive is preceded by a negative, but this soon disappears as the back takes on a faint even colour. The positive then follows.

Of these separate points I will treat in a further article at a future time; but, in any case, the protective power of the quickly reduced film of silver can be deduced from these observations. R. E. Liesegang.

AN IMPROVED FLASHLIGHT.

The patentee, Mr. York Schwartz, observes:—

"Objects to be photographed are, as is known, oftentimes illuminated, *i.e.*, suddenly or momentarily lit up by aid of an easily inflammable and quickly combustible mixture that contains magnesium, aluminium, or an equivalent substance. This mixture is generally employed in the form of a conical heap, the free surface of which is very small in comparison to the volume of the material, and the intensity of the light emitted does not correspond to the quantity of the material used, especially as the light produced by the inner portion of the mixture is greatly absorbed or neutralised by the flame resulting from the combustion of the outer part. To obviate this drawback, the mixture has already been used not in the form of conical heaps, but in that of longish heaps or 'trains,' but then the generation of the light is distributed over or through a longer period of time, which again is very disadvantageous for the photographing of some kinds of objects.

"I now propose to mix the lighting material with an easily inflammable and quickly combustible cementing medium, for instance, with a solution of pyroxyline in ether and alcohol, and to bring this mixture into the shape of a foil of suitable size. After the foil has become dry, it may be hung up by means of a wire, and then lighted. The surface of the foil is considerable in proportion to its volume, and there is practically no absorption of light during the combustion. The material burns with a very great quickness, and the full intensity of the light is at once attained. I am therefore enabled to use less material than has heretofore been required in order to obtain a certain definite volume of light.

"Instead of mixing the lighting material directly with a solution of the cementing medium, I may mix it first with the dry cementing medium, and then add the dissolvent for the latter to that mixture, or I may form foils of the cementing medium, and enclose a layer of the lighting material between two of said foils, or provide one such foil on either side with a layer of said lighting material. In fact, a great many variations may take place with regard to the manner of combining the lighting material with the cementing medium, and I wish to be understood that I do strictly confine myself to the examples mentioned.

"Other advantages afforded by my novel method reside in the facilitation of, first, the handling of the material; and, second, the proportioning or adjusting of the quantity that is requisite or sufficient for one photographic or like operation, and I wish it further to be understood that I do not confine myself to employing my novel method solely for such lighting materials as are used for photographing purposes,

as the same is equally applicable for pyrotechnic purposes, such, for instance, as in production of the so-called Bengal lights, especially where the latter are employed for signalling purposes.

"The size and shape of the lighting foils may greatly vary, and is, as a matter of course, dependent on the volume of light required and the purpose for which the light is to be used."

Mr. Schwartz claims: 1. As a new article of manufacture, a foil consisting of an easily inflammable and quickly combustible lighting material, and of a cementing medium for creating cohesion between the particles of the same. 2. In a combustible composition for illuminating purposes, the combination with an easily inflammable and quickly combustible lighting material, of a cementing medium for the particles of the same, said composition being made up into a form or forms most suitable for rapid combustion.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

Leeds Meeting, July 13–18.

The following is the programme of the week's arrangements:—

Monday, July 13.

Opening of the Convention. Reception by the Mayor, the Right Hon. W. L. Jackson, M.P., in the City Art Gallery, at 7.30, followed by the Presidential address and exhibition of lantern slides, illustrating the Shrewsbury Convention and Bolton Abbey and Woods (Tuesday's excursion).

Tuesday, July 14.

Bolton Abbey and Woods. By train from Midland Station at 9.27. Returning from Bolton Abbey Station at 5.39. Carriages from Bolton Abbey Station to Abbey and Strid. Tickets, including luncheon, 5*s.* 6*d.* each. Luncheon at the Devonshire Arms, Bolton Bridge (¾-mile from the Abbey) at four o'clock.

Route A.—Leader, Dr. Thos. Thresh. Leaving Bolton Abbey Station by conveyance, the Abbey will be reached by a drive of a mile and a half. Bolton Abbey was founded about 1120, for monks of the Order of St. Augustine, and is beautifully situated on the south side of the River Wharfe. Near the Abbey is Bolton Hall, one of the seats of the Duke of Devonshire. From the Abbey, members will work up the south side of the river to the Strid, and on the return cross the wooden bridge and work up and down the stream on the north bank to the stepping-stones, and there cross to the Abbey. The Strid is two miles from the Abbey.

Route B.—Leader, Mr. J. H. Walker. By carriage from the Station to the Abbey, and at once cross the stepping-stones and work down and up the north side of the river to the wooden bridge, which cross to south bank of the river and go up to the Strid, then return along the south side of river to the Abbey. The Strid is two miles from the Abbey.

Route C.—Leader, Mr. Godfrey Bingley. By carriage from station to the Strid. After photographing about the Strid, cross the wooden bridge and work up and down the river on the north bank, and cross to the Abbey by the stepping-stones. About two miles.

The Strid is a narrowing of the rocks where the Wharfe rushes through a confined space. *As there have been numerous fatal and serious accidents to persons attempting to jump over the stream at this point, it is hoped no members will make the attempt, as the distance across is very deceptive. In all cases, members wishing to cross the river must retrace their steps to the wooden bridge.*

Papers:—At the Philosophical Hall at 8.30 p.m. *Fixing and Washing of Paper Prints*—A. Haddon; lantern slides illustrating excursions to Kirkstall and York, and former Conventions.

Wednesday, July 15.

General meeting in the Philosophical Hall at 10 a.m. Meeting of General Committee in the Philosophical Hall at 11 a.m., after which visit Yorkshire College (trams pass Philosophical Hall every five minutes. Fare to College-road, 1*d.*). The Convention Group will be taken at the College about noon.

Afternoon excursion to Kirkstall Abbey. Leader, Mr. Washington Teasdale. Trams to near the Abbey pass the Queen's Hotel every ten minutes. Fare, 3*d.* Kirkstall Abbey is situated on the left bank of the River Aire, about three miles from Leeds. The Abbey (Cistercian) was founded by Henry de Lacy in the year 1152. In 1889 the Abbey and adjoining grounds were purchased by Colonel J. T. North, and presented by him to the city of Leeds. At that time the Abbey was very picturesque, many of the walls being covered with ivy, and numerous trees were growing about the ruins. Unfortunately, for the preservation of the ruins, the Corporation found it necessary to remove the ivy from the walls and cut down the trees, so that now the Abbey has lost much of its former beauty.

Annual dinner and smoking concert at Queen's Hotel, 7 p.m. Tickets, 5*s.* each.

Thursday, July 16.

Excursion to York. The following gentlemen of York have kindly promised to lead the different sections: Dr. Tempest Anderson, Mr. John Saville, Mr. H. M. Platnauer, Mr. Geo. C. Dennis, Mr. Watson Hirst. By train from New Station, North Eastern Railway, at 9.5 a.m. Returning from York at 6.20. Tickets, including luncheon, 5*s.* each. Luncheon (hot or cold) at the Royal Station Hotel, 1 to 3 o'clock; and first-class refreshment room (station platform), express luncheon, 1.30 to 3 o'clock. The city of York affords a fine field for the photographer, especially if at all interested in architectural work. In addition to the noble Minster, there are numerous old churches possessing features of interest: the city walls, with the four gates or bars, of Micklegate (1300), Bootham, Walmgate (1648), and Monkgate; Clifford's Tower; the Guildhall, which is best photographed from the Lendal Bridge; and numerous old shops and houses in Fossgate, Petergate, Stonegate; the old buildings in the Shambles being particularly interesting. Near the east end of the Minster is St. William's College, now converted into dwelling-houses, but still well worth a visit. In the grounds of the Yorkshire Philosophical Society (entrance near Lendal Bridge) are to be found the Natural History and Roman Museums, the ruins of St. Mary's Abbey (Benedictine), St. Leonard's Hospital, the Multangular Tower (Roman), &c. The Council of the above Society has generously thrown the grounds open free to members of the Convention, and will also allow the use of the dark room in the Museum for changing plates. The old Manor House, or Palace of James the First (now the Wilberforce School for the Blind) is interesting alike to the photographer and antiquarian. Permission has been given for members to photograph in any part of the palace. Note: Orders for photographing in the interior of the minster may be obtained from the local Hon. Secretary, Mr. Godfrey Bingley. Members wishing to photograph in the choir, ladye chapel, or chapter house, must pay the verger the usual charge of 6*d.*, all other parts of the minster being free. Dark rooms for changing plates (small charge): Mark Midgely, Stonegate; Baurley & Co., Minster Gates; J. Marshall Smith, 15, High-Ousegate; A. Yardley, 99, Nunney-lane.

Helmsley, for Rievaulx Abbey. No special excursion arranged. Trains—Leeds: 7.25, arrive Helmsley, 9.41; 9 5, arrive Helmsley, 11.50. Return—Helmsley: 5.54, arrive Leeds, 9.7; 8.0, arrive Leeds, 10.22. Return fare, 7*s.* 3*d.* Helmsley Castle of no particular interest. There is an old-timbered house in the market-place. Rievaulx Abbey is about three miles from Helmsley, carriages may be hired at the latter place if desired. Tickets for "the Terrace" and Abbey, 1*s.* each.

Papers:—At the Philosophical Hall at 8.30 p.m. *Orthochromatic Photography*—C. H. Bothamley; exhibition of lantern slides, illustrating excursion to Ripon and Fountains Abbey, and former Conventions.

Friday, July 17.

Excursions to Ripon, Studley Royal, and Fountains Abbey. Leaders, Mr. Thos. S. Mason, Fountains Hall; F. W. Bedford, A.R.I.B.A.; Herbert Denison; Godfrey Bingley. By train from New Station, North Eastern Railway, at 7.50 (arriving at Ripon at 9.1). Returning from Ripon at 6.20 (twenty-five minutes should be allowed for walking from hotel to station after lunch). Conveyances from station to Fountains Abbey and back (two miles), also from the Minster, about noon for Fountains and back. All conveyances will return from Fountains about 3.45. Tickets, including luncheon, 6*s.* 6*d.* each. Luncheon at the Unicorn Hotel, Ripon, at 4.20. Light refreshments can be obtained on payment at the "Canal Gates," Studley. Permission has been granted for members to photograph the Minster any time except during the services, which commence at 12.15 and 5.15. Those desiring to photograph the Minster had better do so on their arrival at Ripon, and then proceed to Fountains a little before noon. The only point of interest in Ripon is the Minster, the best view of which is obtained from the south, near a foot-bridge crossing the River Skel, about ten minutes' walk from the station. Formerly the cathedral had three spires: in 1660 one of these fell, and, four years afterwards, the remaining two, being considered unsafe, were taken down. Dark rooms at Ripon for changing plates: Mr. H. B. Rudd, chemist, 29, Westgate; Mr. C. Watson, photographic artist, Kirkgate. The grounds at Studley Royal, the seat of the Marquis of Ripon, present many beautiful features. The distance from the "Canal Gate" (the point to which carriages are allowed to drive) to the Abbey by the upper route is one mile, and by the lower road about a quarter of a mile less. Fountains Abbey (Cistercian) is said to be one of the finest and most perfect monastic houses in England. Near the Abbey is the old mansion of Fountains Hall, which will afford several pleasing photographs. By the kind permission of Thos. S. Mason, Esq., members may change plates in a small dark room which will be found in the yard at Fountains Hall, and also in one of the rooms of the Abbey. Permission has been given to photograph the interior of Studley Church, which will be seen on the right before entering the "Canal Gates." The church is modern, but the interior is very fine.

Papers:—At the Philosophical Hall at 8.30 p.m. *Photography at the Seaside*—F. M. Sutcliffe; exhibition of lantern slides—Knaresbro', &c., and former Conventions. Council Meeting.

During the week there will also be probably demonstrations of *Photogravure, Colour Photography by the three-colour method, Novelties connected with the Röntgen Rays.*

Saturday, July 18.

Excursion to Knaresbro'. Leaders, Rev. W. E. Hancock; Mr. J. W. Addyman. By train from New Station, North Eastern Railway, at 8.30,

arriving at 9.35; 10.2, arriving at 11.25. Return trains from Knaresbro' at 5.47, 6.17, and 6.50 p.m. Tickets, including luncheon, 4*s.* 7*d.* each' Tickets for this excursion are available for return from Knaresbro' or Harrogate until the following Monday. Luncheon at the Elephant and Castle at 2 p.m. Dark room (small charge) at C. B. Southwell's, High-street. Various sizes of Ilford plates stocked. The town of Knaresbro' is very picturesquely situated on the banks of the river Nidd, and is about three miles from the well-known health resort of Harrogate. Good views of the town and Castle can be obtained from each side of the river, especially from the Long Walk on the south bank of the stream. The chief places of interest in addition to the views up and down the river are: the Castle, Dropping Well, St. Robert's Chapel, Fort Montague, and Rock House; and, about half a mile from the lower bridge, St. Robert's Cave and Grimbold Crag. A small charge is made for admission to the Dropping Well, St. Robert's Chapel and Cave. Plumpton Rocks are about two miles from Grimbold Bridge and four from Harrogate, and several places of interest may be reached by a short railway journey from Harrogate.

PLACES OF INTEREST.

Leeds. There is not much of photographic interest in the city of Leeds. Although there are numerous good buildings in the city, probably the Town Hall is the only one that will have any attraction for members of the Convention.

Kirkstall Abbey is about three miles from the centre of the city, and may be reached by tram or rail. (See Wednesday's excursion.)

Adel Church. About five miles from the city, and two miles from the Headingley train terminus (fare 3*d.*), is a small but very interesting old church dating from the twelfth century. The old Norman porch is considered by archæologists to be the finest in the country. There is also a fine Norman arch across the nave.

Roundhay Park, three and a half miles from Leeds, may be reached by tram (changing at Sheepscar into the electric tram) or by wagonette from Briggate. This Park is beautifully situated, is very extensive, but contains only a few features of interest for the photographer.

The Yorkshire College is situated in College-road, Woodhouse-lane, and was built from designs prepared by Mr. Alfred Waterhouse. Permission has been given for members to look over the College, and it will be visited after the morning meeting on Wednesday. Trams on the Headingley line pass Queen's Hotel and Philosophical Hall every five minutes. Fare 1*d.*

GENERAL INFORMATION.

Application for membership should be made through the Hon. Secretary, or through the Local Hon. Secretary. The subscription is 5*s.* per annum, and is due on January 1 in each year, and carries with it admission to all the meetings and to the Exhibition throughout the week, and liberty to purchase tickets for the excursions.

An Exhibition of Photographs and Photographic Apparatus will be held in the Philoeophical Hall from July 13 to 18, between the hours of nine a.m. and nine p.m. Members must produce their badges on entering. The public will be admitted on payment. Tickets, 6*d.* each.

A special and attractive feature of this year's Exhibition will be a large collection of modern Pictorial Photographs (kindly got together and arranged by the President, Mr. H. P. Robinson), comprising pictures by the leading exhibitors of recent years, showing the great advances made, both in portraiture as well as in landscape work, up to the present date by photography.

The Annual Meeting will be held at the rooms of the Leeds Philosophical Society on Wednesday, July 15, at ten a.m.

The Queen's Hotel (Midland Station) will be the Convention headquarters during the meeting.

Group.—The Group will be taken, weather permitting, at the Yorkshire College, on Wednesday, July 15, about noon, by Mr. Donald McIver, of 8, Bond-street, Leeds. Price, in silver or platinotype, mounted, 15 × 12, 5*s.*, or 12 × 10, 4*s.* each.

Dinner and Smoking Concert.—The Dinner will be held at the Queen's Hotel (headquarters), on Wednesday, July 15, at seven p.m., to be followed by a Smoking Concert. Tickets. 5*s.* each, to be obtained of the Hon. Secretaries. Evening dress optional. Ladies will be welcome at the Dinner and Concert.

Members on arrival are requested to enter their names, full addresses, and where staying in Leeds in the signature book in the rooms of the Leed Philosophical Society.

The Mechanics' Institute and Literary Society, Cookridge-street, a few minutes' walk from headquarters. The Directors of this Institution have kindly given permission for visiting members to have free use of the Reading-room during the Convention week.

Dark Rooms.—Queen's Hotel, headquarters (for changing only); Philosophical Hall (for changing only); Messrs. Reynolds & Branson, Commercial-street; Messrs. Pearson & Denham, 5, New Station-street; Mr. C. C. Vevers, Market-street, Briggate; Messrs. R. H. White & Co., 18, Park-row (changing free, small charge for developing).

HOTELS AND TARIFFS.

Queen's Hotel (Headquarters. Midland Railway).—Private dining-room, private smoking-room. Bedroom, light, and attendance, from 4*s.* Table-d'hôte breakfast, 2*s.* 6*d.* Table-d'hôte lunch, 3*s.* Table-d'hôte dinner, 5*s.* Meat tea, 2*s.* 6*d.*

Dinner and Smoking Concert to be held at Queen's Hotel.

Great Northern Railway Station Hotel.—Private Smoking-room. Bedroom, attendance, and breakfast, 6*s.* 6*d.* Luncheons, 2*s.* 6*d.* and 3*s.* Dinners, 4*s.* 6*d.* Daily terms, inclusive, 10*s.* 6*d.*

Griffin Hotel (Boar-lane).—Bed, attendance, and breakfast, 5*s.* 6*d.* Table-d'hôte luncheon, 2*s.* Dinners, from 3*s.* 6*d.* Meat tea, 2*s.*

Victoria Hotel (Great Georges-street, back of Town Hall).—Bed, attendance, and breakfast, 4*s.* 6*d.* Dinners, 2*s.* 6*d.* Meat teas, 2*s.*

Trevelyan Temperance Hotel (Briggate end of Boar-lane).—Bed, attendance, and breakfast, 5*s.* Luncheons, 2*s.* Dinners, 2*s.* 6*d.* Meat teas, 2*s.*

Note.—No discount from any of the above terms.

THE PHOTOGRAPHIC SALON, 1896.

THE Photographic Salon, 1896 (fourth year), will be held at the Dudley Gallery (Egyptian Hall), Piccadilly, London, W., from September 24 to November 7, 1896.

The aim of the Committee is to exhibit only that class of work in pictorial photography in which there is distinct evidence of personal artistic feeling and execution.

Careful consideration will be given to all pictures entered for exhibition, and a selection of works of pictorial merit made by the Committee. Pictures which have already been publicly exhibited in London will not be accepted. Pictures sent for exhibition to any other Exhibition open in London at the same period are liable also to be disqualified. No awards are offered, and no charge made to exhibitors. Exhibitors will be entitled to a season ticket. Arrangements will be made for the sale of pictures, if desired, and a commission of fifteen per cent. will be charged on sales effected.

The following are the conditions of entry, &c.:—

1. Each picture must be separately framed, and each frame must bear on the back name of exhibitor, number and title of picture, and price, if offered for sale, corresponding to the particulars on the entry form.

2. Pictures will be received at the Dudley Gallery *only* on Monday, September 14, from ten a.m. to six p.m.

3. They must be delivered carriage paid, accompanied by their entry form, and without packing or wrappers of any kind, either personally or through an agent.

4. The well-known packers and exhibition agents, Messrs. Dickses & Co., of 7, Ryder-street, St. James's, S.W., will undertake to receive, deliver, and return exhibits on the following terms, viz., they will collect (or receive and unpack) and deliver at the Gallery; also, if rejected, and at the close of the Exhibition, will remove from the Gallery and redeliver in London (or repack), for the sum of one shilling each for pictures up to three feet long outside the frame, and one shilling and sixpence each above that length. All frames remaining in their warehouse after the close of the Exhibition without instructions from the owners will be charged at the rate of threepence per week.

5. Pictures which are not accepted must be removed from the Gallery on Monday, September 21, between the hours of ten a.m. and six p.m. If not so removed they will be warehoused at Messrs. Dickses'a at the risk and expense of owners.

6. At the close of the Exhibition, all exhibits must be removed on Monday, November 9, between the hours of ten a.m. and six p.m. If not removed, they will be warehoused as stated in Clause 6.

7. Correspondence relating to the forwarding or return of exhibits should not in any case be addressed to the Secretary. The Committee accept no responsibility except while the pictures are actually in their charge at the Gallery.

8. An insurance is effected on the pictures hung for exhibition.

NOTES FROM THE WEST OF SCOTLAND.

THE event of the week has been the opening of the Corporation Exhibition at Camphill House on the 3rd inst.

The Parks and Galleries Committee issued invitations to a goodly number of citizens, as well as professional and amateur photographers in Glasgow, among those who came from a distance, and who were favoured with invitations, being Mr. Crookes, of Edinburgh, and Mr. Charles Reid, of Wishaw.

Of local workers there was a very large turn out. The company assembled in City Chambers prior to driving over to the Exhibition, and among those present we noticed the following well-known workers:—Provost Stuart, Messrs. Mason, Annan, Ralston, Lang, Morison, Oliver, Armstrong, Watson, Warneuke, Goodwin, Laing, Lindsay, Miller, Duncan, Todd, and about a hundred others.

Baillie Shearer, in opening the Exhibition, stated that it gave the Parks and Galleries Trust great pleasure to see so many present interested in photography, and heartily thanked those gentlemen who had rendered such valuable assistance in gathering together such a fine collection of work as they saw around them.

To say that from every standpoint the Exhibition is unique does not overstate its value, and probably no other Exhibition ever held in Glasgow, or in the United Kingdom for that matter, could be compared with it from an historical or educational standpoint.

In number one room alone the entire history and progress of photography, from its inception by Daguerre down to the latest phase of photo-mechanical work, is shown, and any student of photography who carefully studies the exhibits in this room alone will learn much indeed.

Mr. Paton, the Curator of the Corporation Galleries, accompanied those present at the opening ceremony, and briefly described the various works of interest shown.

An excellent catalogue has been published, and the Exhibition will be open free to the public for the next three months.

The recently formed Professional Photographic Society of Glasgow has made a good and practical start. One of the abuses to which professional workers were subjected was an exorbitant charge by the Corporation for water. The action of this new Society has succeeded in getting these charges very much reduced. We understand the Council have in view the dealing with other items of economy which affect the trade generally.

THE W. H. HARRISON FUND APPEAL.

Allow me to appeal to the members of the local societies and clubs, and to ask that they may follow the excellent example of the Brixton and Clapham Photographic Club, and the Manchester Photographic Society, by making a collection from among the members and forward them through the Hon. Secs. to

FREDK. H. VARLEY, 82, *Newington Green-road, London, N.*

The Inquirer.

*** *In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* JOURNAL *useful and instructive.*

REPRODUCING NEGATIVES.—J. HASTIE writes: "I should like to practise carbon printing by single transfer; but, rather than strip my negatives, I would reproduce them in reverse if there were any cheap and simple method available. Glass plates are too expensive for the job, and somewhat uncertain; but, if the quality of image is sufficiently good, I see no reason why paper negatives should not be made both cheaply and with certainty. Will any reader who has experience in this direction advise me as to the probable feasibility of the plan and the best sort of paper to use?"

"CHESSBOARD" SCREENS.—"I have read lately of 'chessboard screens for half-tone work; these, I presume, are screens in which the pattern consists of lines of alternate black and white squares placed side by side or alternate lines of black and white squares placed diagonally. Are such obtainable commercially, or how are they produced? They can scarcely be ruled in the ordinary way.—BETA." A patent has been recently taken out for such screens, but we have, so far, no details as to mode of production, nor can we say whether they are on the market.

METHYLATED SPIRIT.—J. G. E. asks: "How can I tell the difference between ordinary (mineralised) methylated spirit and 'finish?' Formerly, before the introduction of the mineral naphtha, it sufficed to pour a little of the spirit to be tested into a glass of water, when 'finish' produced a cloudy precipitate and the pure spirit remained clear or nearly so. Now either produces cloudiness with water. I have obtained a sample for burning which behaves so badly, clogging the wick-holder and refusing to burn after a very few minutes, that I am convinced it contains gum, though the dealer who supplies it says it is 'burning spirit.' How can I decide?"—We should say you would have very little difficulty in deciding by pouring a little on to a piece of *cold* glass, when on evaporation the gums would "chill" and form a surface like ground glass. If some of the spirit were evaporated in a small basin or saucer, so as to concentrate the solution of gum, and then allowed to get cold, the effect would be more pronounced.

CLEANING OLD NEGATIVE GLASS.—W. HOWARD wants to know "the best" way to clean off old negatives films. He says: "I have a large number of spoilt plates which I might use up in a variety of ways if they were clean, but I find it takes me half an hour or so to get the old film off a single one, and then it is by no means *clean*. Which is the best and quickest way to proceed? I am sure many others besides myself would be glad of some ready method of utilising old negatives."—Perhaps some of our readers can name "the best way;" we "give it up."

SCREEN KINETOSCOPY IN 1888.—Mr. A. L. HENDERSON asks: "Will you please inform me who was the exhibitor of the moving photographs on the screen that were exhibited at the last International Brussels Exhibition, about the year 1888? I have not seen any results equal to them."—Perhaps some of our readers can give Mr. Henderson the information he seeks.

News and Notes.

ROYAL PHOTOGRAPHIC SOCIETY.—Photo-mechanical Meeting, Tuesday, June 16, at eight p.m., at 12, Hanover-square. *Collodio-bromide and Transparencies for Photogravure*, by Mr. E. Sauger Shepherd.

SINCE his return to England, Mr. Whistler has devoted much of his time to a new series of lithographs of London and district, one of which—a view of the Thames looking towards Westminster—will be among the supplements to the first part of the new volume of the *Studio*, due about the middle of June.

THE PHOTOGRAPHIC CLUB.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, June 17. Mr. W. D. Welford will introduce a discussion upon the subject of *Art and Science as an Educational Factor in the Advancement and Progress of Photography.*

X RAYS IN PIRACY.—The pitiless pirate scanned the distant horizon with one of his eagle eyes. "Ha!" It was a short word, but there must have been a motive for it. "A sail! a sail!" Turning to his first mate, he commanded him, with a fearful oath, to run up the regulation flag. That person replied that there wasn't one, as the only flag they ever had was shot away in the last affair. Was the pirate chief rattled? Nay! For the bold buccaneer to rush down into his cabin, bring up his Röntgen camera, and, by means of the X rays, to take an instantaneous photograph of the mate's skull and of a couple of cross bones from his twisted leg was but the work of a moment, and in a wink the sable pennant was flying from the foretopsail of the saucy *Plankwalker*. From that instant, as is usual in such cases, all was excitement.—*Detroit Free Press.*

A DOG'S VANITY.—The Hôtel Vendome, in San José, is the home of a pretty Skye terrier named Nellie. She attracts a great deal of attention from the guests. Cameras are plentiful among them, and nearly everybody who owns one wants a picture of Nellie. Those before whom she has posed have been in the habit of giving her something to eat, and at present Nellie does not want anything better than to have her picture taken. If she sees anybody walking along the streets with a camera, she will run in front of them and stand on her hind feet, making every effort to look her prettiest. If her request is complied with, she has several "poses" that she will gladly take in succession for the purpose of having them "snapped." She knows when the exposure has been made, and always jumps around as soon as she hears the shutter click. Nellie's picture can be seen in nearly every large city in the Union.—*Westminster Gazette.*

RÖNTGEN RAYS DEMONSTRATION AT SOUTHWOLD.—On Whit Monday evening a very successful experimental demonstration was given in the Town Hall, Southwold, by Mr. J. Godfrey Martyn, M.R.P.S., before a large and appreciative audience. The apparatus employed was that which Mr. Martyn had lately been using at the Crystal Palace, and with it the hands of four individuals (two each of ladies and gentlemen) were admirably rendered, with shot embedded in two instances. The results were shown at the meeting, besides a goodly series of animal structures and miscellaneous objects, previously taken by the lecturer and thrown upon the screen. The latest form of radiant tube was employed with a powerful Rühmkorff coil, but other earlier forms of Crookes' and Giessler tubes were also shown in action, besides the new Jackson fluorescent screen, which revealed the contents of several boxes and parcels placed in the path of the X rays. The Town Clerk moved a vote of thanks to the lecturer, which was carried by acclamation.

A WARNING TO PHOTOGRAPHERS.—On Tuesday, June 2, at the Alton (Hants) Petty Sessions, with Mr. J. G. Wood in the chair, a man named Vipond was sent for trial at Winchester Assizes on the charge of stealing a camera and slides, with the usual appliances, and also a Gladstone bag, the property of Mr. A. W. Holliday, photographer, 9, Market-street, Alton. From the evidence it was gathered that, a few weeks ago, Mr. Holliday was called

upon by Vipond, who solicited work, and he was given some to do, and kept on for nearly a fortnight. He was then sent out with the apparatus to take views, but; instead of taking views, he proceeded to Portsmouth, pawned part of his employer's property for 25*s.*, sold the rest to private individuals, and eventually found himself in the hands of Police Serjeant Wakford, who, at any rate, has proved himself far from a sleepy individual in tracking thieves. Of course, such practice is put a stop to for a little time, at least, and we congratulate Mr. Holliday on the recovery of his property, and warn all such business men to be careful whom they employ before entrusting them with their valuables. The annoyance and unpleasantness attached to such cases are not the least things to be thought of.

Bristol International Triennial Photographic Exhibition.—The Council of the Bristol and West of England Amateur Photographic Association begs to announce that the Triennial International Exhibition of Photographs, Apparatus, Appliances, and Processes, will be held in the galleries of the Academy of Arts, Queen's-road, Clifton, Bristol. To be opened on Monday, December 14, 1896, continuing open till Saturday, January 23, 1897. Apart from photographs for competition, the Council will esteem it a favour if those who have any interesting examples of the history and progress of photography will kindly lend them for exhibition. The following is a list of medals which will be awarded by a Committee of five Judges—four being well-known photographers, and one an eminent painter, three of the Judges not being members of the Association:—A gold medal for the picture or series of pictures having already received an award at any previous exhibition, and which, in the opinion of the Judges, possesses the highest degree of merit, irrespective of size or subject. 1. Two silver and two bronze medals for landscape or seascape, of not less than $6\frac{1}{2} \times 4\frac{3}{4}$ size. 2. Two silver and two bronze medals for marine subjects of not less than $6\frac{1}{2} \times 4\frac{3}{4}$ size. 3. One silver and one bronze medal for set of not less than six landscapes or seascapes of 5×4 or under. 4. One silver and one bronze medal for architectural subjects. 5. One silver and one bronze medal for portrait or series of portraits of $8\frac{1}{2} \times 6\frac{1}{2}$ or under, taken direct. 6. One silver and one bronze medal for portrait or series of portraits above $8\frac{1}{2} \times 6\frac{1}{2}$, taken direct. 7. One silver and one bronze medal for *genre* pictures. 8. One silver medal for the best picture or series of pictures of any subject taken by artificial light. 9. One silver and one bronze medal for enlargements of any subject and by any process, provided both the original negative and enlargement be entirely the work of the exhibitor. An unframed mounted print from the original negative to accompany each exhibit. 10. A silver medal for the best transparency or series of transparencies (stereoscopic or otherwise), not being lantern slides. 11. One silver and one bronze medal for sets of twelve lantern slides, by any process other than mechanical. Table frames will be provided. 12. One silver medal for botanical or zoological subjects, micrographical, astronomical, or other scientific branches of photography. 13. Two silver medals for heliochrome and other process work. Only ordinary photographic retouching will be permitted on the negatives. The Judges will have the power of requiring the negatives of any picture receiving an award in this class to be produced for inspection. 14. One silver and one bronze medal, to be awarded according to the discretion of the Judges, for improved apparatus, materials, processes, or for any other meritorious productions.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

June.	Name of Society.	Subject.
15	North Middlesex	*Silver Printing and Toning.* W. J. Simpson.
15	South London	Social Evening.
16	Ashton-under-Lyne	Excursion: Wilmslow and Alderley. Leader, Charles Wilson.
16	Birmingham Photo. Society	Excursion: Compton Winyates. Leader, W. Jones.
16	Brixton and Clapham	Ordinary Meeting.
16	Gospel Oak	Character Studies by Flashlight.
16	Hackney	*Printing with Silver Paper.* E. J. Wall.
16	Royal Photographic Society	*Collodio-bromide and Transparencies for Photogravure.* E. Sanger Shepherd.
17	Borough Polytechnic	*Contact Printing and Enlarging on Bromide.* A. Humphreys.
17	Croydon Camera Club	*Hand camera Work.* W. Thomas.
17	Photographic Club	*Art and Science as an Educational Factor in the Advancement and Progress of Photography.* W. D. Welford.
20	Aintree and District	Excursion: Llangollen.
20	Borough Polytechnic	Excursion: Oxted.
20	Hackney	Excursion: East Moulsey.
20	Leytonstone	Special Sale and Exchange Night.
20	Liverpool Amateur	Excursion: Overton and Erbistock.
20	Oldham	Excursion: Chew Valley. Leader, J. W. Cooper.
20	South London	Excursion: Leatherhead. Leader, G. A. Maull.
20	Wolverhampton	Excursion: Warwick.

ROYAL PHOTOGRAPHIC SOCIETY.

June 9,—Ordinary Meeting,—Captain W. de W. Abney, C.B., D.C.L., F.R.S. (President), in the chair.

The Hon. Secretary announced that the following had been elected as the Hanging Committee at the forthcoming Exhibition, viz., Messrs. Cembrano, Hodges, Mackie, Mummery, Sinclair, and W. Thomas; and also that the Hanging Committee, the Judges, and Messrs. Wall, Wellington, and England would constitute the Selecting Committee.

At the conclusion of the ordinary routine business, the chair was temporarily taken by Sir Henry Trueman Wood, M.A., and the President read a paper on

Printing Density in Negatives.

Premising that he had still many points under consideration and in process of discussion by means of experiments, and assuming that his method of measuring the opacity of photographic plates was sufficient, he took as his starting point a negative with every grade of transparency from perfect transparency to an opacity allowing one two-hundredth of the incident light to pass through it, and possessing every shade of gradation between these extremes, the problem to be solved being how much of that range was useful for printing purposes and how much was useless. Such a negative as that indicated, however, would be an intolerable nuisance to work with or to measure, and he had therefore adopted for his experiments a new form of the Warnerke sensitometer, of which he spoke in highly eulogistic terms. He had found that for platinotype printing it was useless to have a negative more opaque in any part than would allow the passage of $\frac{1}{75}$ of the light passing through the least opaque part, though by alteration of the sensitive salt and by development this proportion might be slightly varied. For printing with printing-out papers, his measurements indicated that a negative should only be so opaque in its densest part that $\frac{1}{125}$ of the light passing through the transparent part should be transmitted by the former, all further opacity, though visible to the eye, being useless for printing purposes. It thus appeared that for measurement the negative for printing with P.O.P. might have half as much again of opacity as it should have with platinum papers. The blackness of P.O.P. was considerably greater than that of platinum, the measurements showing that the greatest density of the former only reflected about one per cent. of white light, whereas platinum paper reflected about five per cent. Turning to the physiological effects produced by greys of different degrees of darkness or lightness, Captain Abney referred to a large series of observations which he had made during the past ten years. Taking a series of grey squares, varying between black and white, he found that, if a person were asked to pick out the particular tint which appeared to him to be intermediate between the two extremes, he would not select the grey reflecting the mean of the white reflected from both, but one considerably darker, this peculiarity continuing when similar selections were made from divisions and subdivisions of the original series. Applying this fact to photographic prints, a negative which by measurement might appear perfectly satisfactory might yet give a print which failed to please the eye. He showed strips painted by eminent artists to illustrate their ideas as to the mean of a series of grey tints, and pointed out wherein they differed from the theoretical shades ascertained by measurement.

Mr. Warnerke suggested that paper ruled with black lines with different spaces would have been more useful for Captain Abney's purpose than the squares of various tints painted by artists, as there might then be a perfect numerical relation between the black and white.

Mr. W. E. Debenham referred to the reversal of the image in platinotype printing, and showed a print in which this had occurred in the deep shadows; he attributed it to the fact that, in quick printing, the products of chemical decomposition by light could not get away. He thought that the visual selection of greys would very much depend upon the strength of the light in which the tints were examined.

Captain Abney, in reply to Mr. Warnerke, said that a paper was read at the Royal Society, many years ago, in which the use of black and white lines was suggested, and Sir George Stokes pointed out that the physiological effect of the lines need not be the same under all circumstances; he therefore thought it better to employ a graduated scale of greys, of which the whiteness could be accurately measured. He confirmed Mr. Debenham's remarks as to the reversal of the platinotype image, and as to its cause, and also as to the visual mean of greyness varying according to the light in which the selection was made.

A vote of thanks was passed to the President for his communication.

Mr. C. F. Cross then read a paper by himself and his partners, Messrs. E. J. Bevan & C. Beadle, on the subject of

Cellulose and its Derivatives.

In reply to the question, What has cellulose to do with photography? the authors expressed the opinion that the science of photography was intimately bound up with coming developments of the greatest moment, that it was important that its basis should be broadened as much as possible, and that cellulose was destined to play a considerable part in the advance of the science. Particular attention was directed to the various forms in which cellulose could be obtained in solution, there being certain compounds of the metals which in aqueous solution readily dissolved it, viz., zinc chloride, zinc chloride dissolved in hydrochloric acid, or solutions of cuprammonium. Photographers might make an interesting demonstration by puttiog a platinum print face downwards upon a resistent surface, such as glass, porcelain, or asbestos, and pouring over it a solution of zinc chloride in hydrochloric acid, when the paper would be dissolved, leaving the platiuum image upon the support. The paper described very fully several compounds of cellulose, and a number of different varieties were exhibited, and examined by the audience with much interest, the new "artificial silk," or "lustra-cellulose," receiving special attention.

After some remarks by Messrs. J. W. Swan, J. Spiller, T. Bolas, and S. Davies, a vote of thanks was accorded to the authors of the paper, and the meeting concluded.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

June 4.—Mr. H. C. Rapson in the chair.

Mr. Edward Simpson was elected a member.

Mr. A. L. Henderson showed a device to be attached to the camera front for facilitating the changing of lenses. The arrangement consisted of a circular plate of aluminium revolving in a flange and carrying on its face three separate pairs of lenses for stereoscopic work, any pair being brought into action by partially revolving the disc. Any one of the six lenses could be used by

means of a second plate at the back of the first, which could be so adjusted as to close the second opening, the device also allowing of the lens chosen being placed at the top, bottom, or either side of the camera front.

Mr. Freshwater showed an aluminium plate of graduated thickness, used for measuring the relative speeds of tubes for X ray photography, made by Reynolds & Branson of Leeds, and a photograph taken by its means.

The Hon. Secretary considered that, unless all the conditions were constant, which was rather unlikely, the instrument was not of much utility.

The Hon. Secretary read a paper on

The Measuring of Stops.

Some years ago the Photographic Society of Great Britain established a system known as the Universal Standard, taking as basis the intensity of a portrait lens, the aperture of which is one-fourth of the focus, usually expressed as *f*-4. Of the Universal Standard this is No. 1, and it was proposed that others of a series should be fractional of this, so that each successive stop should necessitate twice the exposure of that preceding it. These stops are numbered 1, 2, 4, 8, 16, 32, &c., representing multiples of the exposure given with No. 1. This standard might have become universal on account of its convenience, but for one error. Objections have been raised to it on the Continent, and he thought, on the most important point of aperture, the English system wrong. Attention has been called to this lately by the improvements made possible by the new Jena glass. The system of stops adopted by German opticians is based upon the ratio of effective aperture and focus, and not, as in the English method, diameter of stop and focus. With reference to whether the new German lenses are as rapid as they would appear, any given stop, with lenses of the same focus, is smaller in German instruments than in English. With only two classes of lens that the author is acquainted with is the English system true—the single landscape and Dallmeyer's rectilinear landscape, in both of which the stop is placed in front, and the light is intercepted before the glass is reached. In the case of a doublet, however, the light passes through the front combination and converges before meeting the stop, being consequently more intense where it passes this spot, and it is evident that at this section as much light will be conveyed by a smaller circle as could be done by a larger one at the front of the lens. A stop of same diameter as the front lens will convey no more light than a smaller stop the size of the circle of convergent light at the diaphragm section. The author has measured by the Continental method a Steinheil aplanat, Series 3, of $10\frac{9}{16}$ inches focus, and a Goerz anastigmat of $10\frac{3}{4}$ inches. After focussing on a distant object and ascertaining the focal length by Grubb's method, the focussing screen was replaced by a piece of card having a pinhole through the centre. A piece of bromide paper was then exposed in the lens cap through the pinhole, which, being situated at the principal focus, the light proceeding from the lens would be in parallel rays, and the image of the aperture would be impressed on the paper. The result was as follows :—

	Focus.	Effective Aperture.	Focus divided by diameter of stop.
Goerz anastigmat.....	$10\frac{3}{4}$ in.	*f*-8	*f*-9·3
Steinheil rapid aplanat ...	$10\frac{9}{16}$,, ...	*f*-7·5	*f*-8·4

The English system is thus incorrect, and the error would, therefore, extend to the whole series. This point of aperture is, however, not the only one to be considered in arriving at the rapidity of a lens. The greater the separation of the two halves of a doublet, the less illumination would there be at the margins. The number of reflecting surfaces in a triplet must also tend to render them slower than doublets. Then there is the absorption of light by the glass, especially where heavy flint glass forms part of a lens. From some tests made, the author finds the rapid Steinheil has the advantage in transparency over the Goerz, but the Steinheil wide angle shows more falling off. The Concentric and the new Ross-Zeiss *f*-8 show very good results. With reference to the claim that the new Jena glass has less absorption than the old crown and flint glasses, it should not be forgotten that with one exception—the Concentric—all the lenses of this new series are much thicker. It is often said that long-focus lenses require longer exposures than short-focus, and, although this opinion has not been accepted by all, there seems good reason for the idea, the lenses being thicker and wider apart proportionately to their diameter. Eder's *Jahrbuch* for 1891 contains an article on the subject of absorption, by Dr. Miethe, who found that a certain lens required with an increase of aperture considerably more than its proportionate exposure, and which he put down to the absorption by the flint glass of the negative lenses in the combination which happened to be thicker at the margin than the centre. He conducted a number of experiments with Jena and some old kinds of glass, and a table which he gives shows the Jena to possess some advantage, especially in evenness between flint and crown; but the author doubted if this advantage was retained in the lenses themselves on account of their being mostly much thicker than the old rectilinears. Messrs. Hurter & Driffield have given a very perfect system for the measurement of speed and exposure of dry plates, but he believed lenses were factors in the problem also. He wished to point out that the standard of their intensity was only approximate, and that for most lenses the universal standard started on a wrong basis, thus affecting the stop values throughout. This error might be set right by substituting the effective aperture for the fraction of the focus as the starting point. A lens aperture of *f*-4 might replace stop aperture *f*-4. A standard of intensity would also assist, and lenses might be numbered to represent the real intensity under a given angle, attention being given to absorption and other factors which mar their efficiency.

Mr. Beckett did not know that any better work would be done if the correct exposure were known. If three seconds were the correct exposure as generally understood, he would always give six, and maintained that a better picture would result by so doing. What was generally known as correct exposure was a bare exposure, and he would give more. He did not think a plate worth much unless it could stand twelve times this correct exposure. He thought it generally the case that plates were under-exposed. He pleaded for the English method of measuring stops, and said that some of the German lenses were now marked by the English method.

Mr. Atkins said that, when mounting lenses himself, he had always made the apertures of stops by the Continental method.

Mr. Mackie stated that there was no such term as correct exposure in itself. Development is a factor for consideration.

Mr. Henderson disagreed with Mr. Beckett that under-exposure was the rule, and thought the reverse.

The Secretary agreed with Mr. Mackie that the ordinary amateur did not appreciate the difference in value of subjects, and said that an amateur would do well to study Hurter & Driffield's work.

PHOTOGRAPHIC CLUB.

June 3,—Mr. Stretton in the chair.

Mr. Drage mentioned that Mr. Alexander Cowan had met with an accident and fractured his leg.

The Hon. Secretary was asked to write to Mr. Cowan expressing the condolence of the members present, and the hope of his speedy recovery.

Mr. Wallis showed some prints upon some samples of paper which had been sent to the Club; he also showed prints from the same negatives on Ilford P.O.P., so that members could compare results. He mentioned that the new paper took about three times as long to print as the Ilford did.

Mr. Welford handed round some work which he had done on Wellington's new films.

Mr. J. B. B. Wellington then gave a demonstration upon

The Wellington Stripping Film.

In his opening remarks he said that the notion of supporting the sensitive film upon a flexible support was not new—in fact, it was as old as photography itself. The advantages gained by the employment of glass had counterbalancing drawbacks, and thus the attention of inventors had been constantly directed to the discovery of some kind of flexible, and preferably transparent film. Scott Archer had invented a film in which gutta percha dissolved in benzole was the support. In 1868, Mr. Geo. Dawson had a somewhat similar idea, and, in 1869, Mr. Warnerke invented the well-known film bearing his name. Pumphrey, of Birmingham, and Stebbing, of Paris, had each devised films, and they were followed by Morgan & Kidd and the Eastman Company, who coated emulsion direct upon a very fine quality of paper. To get rid of the grain, Warnerke had the idea of coating the paper film with emulsion on both sides. Paper as a support for negative films had never achieved a wide popularity. The Vergara film, in which the support was insoluble gelatine, was the next invention, followed closely by the stripping film of the Eastman Company. After this came the cut celluloid film in pretty much its present form. The Wellington film consists of a paper backing possessing an exceedingly fine grain impregnated with gum copal dissolved in alcohol; this permits the gelatine coating to be easily stripped from the paper when in a wet condition. The prepared side of the paper is coated with a sufficient thickness of gelatine to form a support to the film, and this compound paper and gelatine film is coated with a sensitive gelatine emulsion. The film thus prepared is intended for roll-holders. For using in sheet form, the other side of the paper is also coated with gelatine so as to give an even tension or strain to the compound film. Development, broadly speaking, is the same as for a glass plate, with a single exception, that "pyro and soda" are not recommended. The stripping process is not absolutely necessary, but, being very simple, will probably be generally resorted to. To strip the film, the fixed and washed negative is immersed for a few minutes in a bath which, for want of a better name, is called the "soaking" bath, as follows :—

Formaline	3 drachms.
Glycerine	2 ,,
Ammonia, ·880	1 drachm.
Water	20 ounces.

The addition of the ammonia has the effect of making the film more adhesive to the glass plate upon which it is subsequently dried, but too much ammonia makes the film swell. After soaking in this bath for five minutes, it will be found that the gelatine film can be stripped easily from its paper support. The film must now be laid down upon a piece of clean glass, prepared with French chalk, so that when dry it will strip. It is neither necessary nor advisable to squeegee the film down upon the glass. Mr. Wellington then proceeded to strip a few films which he had brought with him for the purpose, and he invited the Chairman and others present to try the stripping operation for themselves. In every case the stripping was satisfactorily and easily effected.

Mr. Bedding said that he had been using some of the films, and he found them strip quite readily.

Mr. Bridge asked if Mr. Wellington had tried to make lantern slides from the film negatives.

Mr. Wellington reminded Mr. Bridge that he had shown some slides at the Club, which were not only made upon his film, as far as the negative was concerned, but the lantern slides also were produced upon a stripping film.

Mr. F. Haes recalled with satisfaction his use of the old Eastman paper film, and regretted that it could not now be obtained.

Mr. Drage said that the new film would entirely do away with halation.

The Rev. F. C. Lambert and Mr. Mackie questioned whether this would be so, and Mr. Wellington gave an instance in which halation had occurred.

Mr. Fry said that there were two distinct kinds of halation, that due to reflection from the support, and that due to dispersion in the film itself.

Mr. Mackie mentioned a third kind, due to the dust in the atmosphere.

Mr. Bedding passed round prints showing a fourth kind, and the discussion turned for the moment upon halation.

Mr. Welford said he had only one difficulty with the new films. Having explained this,

Mr Wellington replied that his difficulty would disappear if he did not squeegee the stripped films down upon glass, but simply laid them down. Mr. Wellington then took one of the films which he had stripped, and demonstrated how it should be laid down upon the glass without squeegeeing or stretching the film in any way. He avoided air bubbles by placing the film down from the centre first.

Mr. Lambert asked if films which were spoilt by having dried irregularly could be dried a second time?

Mr. WELLINGTON said yes, and added that a film dried with the paper backing upon it could afterwards be stripped. After having drawn attention to the ingenious method by which his rolls of films could be fitted into any of the existing roll-holders, Mr. Wellington was cordially thanked by the Chairman for his most interesting and impartial statement of the merits of his new film.

Brixton and Clapham Camera Club.—June 2, Chairman, Mr. W. Fraser (Vice-President).—A series of slides, *Balmoral and the Western Highlands of Scotland*, was shown and described by Mr. W. H. Whittard. Entries for the members' "Landscape" competition close on the 16th inst. Mr. Horsley Hinton has kindly consented to judge.

Hackney Photographic Society.—June 2.—Mr. W. E. DEBENHAM gave a lecture on the subject of—

LIGHTING,

in the course of which he said that, for distant views, a rather sharp side lighting should be chosen, and the sun should not be too high in the heavens. In photographing distance there was a tendency to get too much flatness on account of the interposed atmosphere. For ordinary landscapes and marine subjects the lighting should be rather decidedly on one side; lighting from behind the subject and from behind the camera in both cases tended to produce flat results. For shutter work it was desirable to have the light rather more behind the camera, and the sky should have some brightly lit clouds to illuminate the shadows. In photographing the human figure good results could be obtained in the open air, and in rooms with proper management. The lecturer showed by diagrams how, in the former respect, the back wall of a house could be utilised in conjunction with a garden wall running at right angles to it. In indoor photography, whether in a studio or in a room, it was a mistake to have a small area of principal light, it tended to produce harshness, as witness the effect of using a single flash lamp. Reflectors were very useful, and the position and placing of these was a very important matter. The reflected light must not be too strong; but ordinarily it was not so, for it could not be so powerful as the original light it reflected. Artificial lighting must be managed on the same principle—a large area of illumination and suitable reflection. This enjoined the use of a number of flash lamps over a large space. For copying work the light should as much as possible fall directly on the subject, and the side lighting should be equal to avoid showing grain; but, in copying hand work generally, such as drawings and paintings, the lighting should be regulated in the direction to agree with that in which the work was originally done. In the course of his lecture, Mr. Debenham dealt very fully with portraiture in rooms and in the studio, illustrating his remarks with diagrams, and replying to the many questions which were asked.

Aintree Photographic Society.—June 5.—During the evening the PRESIDENT (Mr. C. H. Adkins) introduced and explained the various parts of a hand and stand-focussing camera which has been built to his own designs; and, as it contains several new and useful features, he has had the same protected by patent. Another item was the stereo-photo-duplicon, which is now being placed upon the market by J. Fallowfield. One of these had been kindly lent to the Society for the evening. The object of this new patent is to enable one with a half-plate camera and one lens to obtain a stereoscopic picture of either moving or still life, landscapes, &c. Before the close of the business it was decided to have no ordinary meeting in July or August next, on account of the summer holidays.

Edinburgh Photographic Society.—June 3, Mr. J. C. Oliphant, M.A., presiding, when office-bearers for next session were elected. Messrs. H. J. Blanc, R.S.A., and J. C. Oliphant, M.A., were elected Hon. Presidents; Mr. F. P. Moffat, President; and Messrs. James Patrick and A. Eddington, Vice-Presidents. The Secretary (Mr. J. S. M'Culloch, W.S.) and the Treasurer (Mr. George Cleland) were re-elected. There were three vacancies in the Council, and Dr. Scott Lauder and Messrs. James Hay and James Ritchie were elected to fill the posts. The reports of the Secretary and Treasurer showed the Society to be in a very prosperous condition. There were close on 400 members on the roll, seventy-six having joined during the past session. A paper entitled,

ONE WORD MORE ON PHOTOGRAPHY AND ART,

in which the claims of photography to be considered an art were ably put forth, was read by Mr. JOHN WARRACK, jun. The artistic photographer, he held, could, like the painter, infuse an element of personality into his work, and photography, as a means to picture-making, was too often condemned by those who did not fully understand what could be done with the camera in the hands of an artist. Mr. Warrack was warmly thanked for his paper.

Photographic Society of Ireland.—May 28, Annual Meeting, Professor J. A. Scott in the chair.—The election of officers for the coming session took place, with the following result:—*President:* Alfred Werner.—*Vice-Presidents:* Messrs. L. R. Strangways, M.A., and J. A. C. Ruthven, A.M.I.C.E.—*Council:* Messrs. J. Armstrong, J. H. Gane, A. M. Geddis, R. M. Inglis, J. M. Keogh, and George E. Matthews. Members retaining their seats on the Council for another year are Messrs. H. Goodwillie, J. H. Hargrave, B.A., and J. R. Simpson. Mr. W. Bewley was unanimously re-elected Hon. Treasurer, and Mr. V. E. Smyth was elected Hon. Secretary, in the room of Mr. Ruthven, who resigned. A cordial vote of thanks was passed to Dr. Scott for the able manner in which he filled the presidential chair during his term of office, and a like vote was passed to Mr. J. A. C. Ruthven for his untiring efforts on behalf of the Society as Hon. Secretary. Mr. Alfred Werner distributed the medals to the successful exhibitors at the Society's last Exhibition. This meeting concluded the session, which in every way proved very satisfactory to the Society.

Patent News.

THE following applications for Patents were made between May 27 and June 3, 1896:—

PHOTO-RELIEF PROCESS.—No. 11,604. "Means for Transforming in Relief Photographic Negatives and Diapositives, or Turned Negatives, without any Copying Process, for Artistic and Industrial Purposes." M. MAGNUS.

CAMERAS.—No. 11,771. "Improvements in Photographic Cameras." W. J. LANCASTER.

KINETOSCOPE.—No. 11,836. "Improvements in Apparatus for Taking and Exhibiting Photographs in Series." J. TERME and A. DE MAROUSSEM.

Correspondence.

INFLUENCE OF AIR ON DEVELOPMENT.

To the EDITORS.

GENTLEMEN,—In reading this week's BRITISH JOURNAL OF PHOTOGRAPHY, I notice the report of a discussion *On the Accelerating Action of Air on a Plate during Development.* I do not make much study of such technical points, but I have repeatedly observed while developing tentatively that no sign of an image appears for a considerable time, perhaps thirty to sixty seconds after the application of the developer. Then, when a few more drops of alkali are put in the measure glass, and the developer is poured off the plate into the measure, thus leaving the plate exposed to the air, the image will come out, sometimes so rapidly as to lead one to fear over-exposure. More than once I have added pyro and bromide, only to find later that the exposure was about correct, after all, and that more alkali was needed to satisfactorily complete development. I remember being taught during my apprenticeship that the less developer used the better the *quality* of the negative, and my experience is that, if enough developer is used to just cover the plate with a wave from end to end as the dish is rocked, the density and gradation of the negative are superior to what is produced when the developer is half an inch deep. Whether this is because the lesser quantity of developer used, as I have indicated, allows the air to reach the plate, I cannot say. I have found a large quantity of developer more likely to give the effect of under-exposure, so far as the absence of shadow detail produces that appearance.—I am, yours, &c.,

CHARLES HENRY HEWITT.

Catherine-terrace, Gateshead-on-Tyne, June 6, 1896.

MR. CHILD BAYLEY ON ART.

To the EDITORS.

GENTLEMEN,—Mr. Child Bayley insinuates that when the Linked Ring hold their Exhibition they carefully confine it to their own works, and only admit a stray "outsider" or two. The object of Mr. Bayley seems evident. "You send to our show at Pall Mall, not to the other one, which is only a sham. *They* don't want anybody's work but their own; the chances are your pictures will not be accepted; therefore, to avoid that, support the old firm, who open their doors and admit everything."

I do not know that it is wrong for a man, even the Assistant Secretary to a society, to boom his own Exhibition, but it should not be done by the aid of mis-statements.

As Mr. Bayley has consented to his paper being published, and possibly circulated widely, it is as well that any one reading it should be acquainted with the real truth, although it may be distasteful to Mr. Bayley to have it stated.

I have extracted the following figures from the catalogue of the Salon Exhibition, 1895, and any one who has a copy can verify them. There were 118 exhibitors, 35 members of the Linked Ring, 83 non-members. There were 323 photographs exhibited, 158 by members of the Linked Ring, 165 by non-members.—I am, yours, &c.,

L. C. B.

GLASGOW PHOTOGRAPHERS AND THE FACTORY ACT.

To the EDITORS.

GENTLEMEN,—Some months ago Mr. J. Stuart, of Glasgow, called a meeting of the professional photographers of Glasgow and district to take into consideration the Factory Act in connexion with the printing department of photographic work.

By the Act, as it then stood, all the printers had to leave work at one hour, at the meal interval (if women or young persons), and during that time printing had to be suspended. In the winter time this was a serious drawback, because, if the prints were left, sun and rain might

occur, and not only would the prints be ruined, but the negatives also in many cases.

The matter was then considered by the professional photographers, and, after a good deal of discussion, it was resolved to apply to the Home Secretary to be put under the Continuous Process Act, to go at different hours, always remembering that no females or young persons work more than five hours at a stretch without rest and a meal.

It will be seen by the enclosed official copy, sent by the Secretary to Mr. Stuart, that he has considered the matter, and they now have the privilege of having their *employées* working at different hours.—I am, yours, &c., G. M.

[Official Copy.]

STATUTORY RULES AND ORDERS, 1896.
No. 330.

FACTORY AND WORKSHOP.

Order of the Secretary of State dated May 1, 1896, extending Special Exception :—Different Meal Hours.

Whereas the Factory and Workshop Act, 1878, section 52, contains a special exception to the effect that the provisions of the Act which require that all the children, young persons, and women employed in the factory or workshop shall have the times allowed for meals at the same hour of the day shall not apply in the cases therein referred to ; and power is given to the Secretary of State to extend such exception to other classes of factories and workshops :

And whereas it has been proved to my satisfaction that in the class of factories and workshops wherein there is carried on the printing of photographs it is necessary, by reason of the continuous nature of the process and the special circumstances affecting such class, to extend thereto the foregoing special exception, and that such extension can be made without injury to the health of the children, young persons, and women affected thereby :

Now I, the Right Honourable Sir Matthew White Ridley, Baronet, one of Her Majesty's Principal Secretaries of State, by this Order, made under Part Two of the said Act, extend such special exception accordingly to factories and workshops in which is carried on

The Printing of Photographs,

subject to the condition that, in every factory and workshop the occupier of which avails himself of this exception, there shall be affixed a notice showing the names of the children, young persons, and women employed in the factory or workshop, and the times allowed to each of them for meals.

Whitehall, May 1, 1896. M. W. Ridley.

ASSISTANTS AND THEIR GRIEVANCES.

To the Editors.

Gentlemen,—My attention has been directed to a letter by Frank Brisley, which appeared in your issue of May 29.

I am asked the question as to what is meant by the sentence where Mr. Brisley expresses the hope that assistants generally, and Mr. Randall particularly will not relax their efforts to promote the establishment of a Photographic Assistants' Branch of the Shop Assistants' Union.

I cannot say what Mr. Brisley means; but, as far as we are concerned we have no such intention. What we have offered to do is to admit photographic assistants to our branches on exactly the same terms as we admit other assistants. At the present moment only a small proportion of the shop assistants have joined the National Union : they need the help of the photographic assistants, and, in return, any assistance that can be rendered by the organization in existence will be given. Any member has the power to bring before the Committee of the branch of which he or she is a member, any grievance under which he or she may suffer, and, if the case cannot be dealt with by the local Committee, an appeal can be made to the executive, and by this means whatever power the organization possesses as a whole can be brought to bear upon any grievance any member may bring forward.

In conclusion, I would like to point out that no organization can hope to do much for its members until a fair proportion of those eligible to join become members, so that it is perfectly obvious that all those assistants who believe in organization should join at once, and then try and urge others to do likewise.—I am, yours, &c.,

Jas. Macpherson, *General Secretary.*
National Union of Shop Assistants, Warehousemen, and Clerks,
Head Office, 55 and 56, Chancery-lane, London, W.C.

THE CARDIFF EXHIBITION.

To the Editors.

Gentlemen,—Probably I am a dullard, and cannot see the connexion, but what on earth have amateurs taking pay for work done to do with my letting the under part of my house for barber's purposes? It suits me, it hurts nobody. An individual did call on me one day last week, and, ignoring the usual courtesy of giving his name, stated in a somewhat erratic and pretentious manner that he was a professional who had joined a syndicate of amateurs formed to run a studio on the Cardiff Exhibition ground. (It takes more than one swallow to make a summer). He said, "You take portraits for 3*s.* per dozen." I did not deny the soft impeachment, but enlightened him to the fact that that sum covered the cost of midgets only.

Now, Gentlemen, Professional *versus* Amateur : I became a professional photographer in 1858, and, as such, have occupied my present premises for thirty-two years (since 1864).

I also claim to be a professional musician, having joined the musical ranks in 1851, and have occupied a seat in the Theatre Royal and other orchestras in Cardiff for twenty-eight years. Thirty-eight years a photographer, forty-five years a musician, and following both professions concurrently. What am I in either—professional or amateur? Is it incompatible for a man to follow two professions? Let Mr. Booth put that question to his friend Mr. Freke, and hear his opinion thereon.

I am one of the few professionally oldest photographers left in Cardiff who began the torture of the silver bath before the advent of *cartes-de-visite*.—Thanking you in anticipation for the insertion of this letter, I am, yours, &c., Alfred Horton.

Central Studio, Caroline-street, Cardiff, June 7, 1896.

To the Editors.

Gentlemen,—It is but a poor defence of the action of the Cardiff Photographic Society, on Mr. Wm. Booth's part, when he asserts that, because professional photographers could not see their way to successfully run a studio in the Exhibition grounds, it thereupon became incumbent on Mr. Wm. Booth and his band of amateurs to take the matter in hand, thus running completely counter to the recognised ethics of amateurism. —I am, yours, &c., The Kaiser.

15, *Newport-road, Cardiff, June* 8, 1896.

To the Editors.

Gentlemen,—With reference to the letter *re* Cardiff Exhibition, which appeared over the name of Mr. A. Freke in your issue of May 22, the facts of the case are as follows :—

The President of the Cardiff Photographic Society was requested by the Executive Council of the Exhibition to form a Committee to work the Photographic Section. This he did, and, taking previous Photographic Exhibitions as a basis, a lump sum was asked for to cover cost of same. This, however, could not be granted, as no provision therefor had been made in the estimates, therefore the Committee ceased to exist.

Later, the President was asked if he could form a Committee to work the section in exchange for certain concessions, one of which was the studio of which Mr. Freke complains. That the Committee did not intend to run the studio themselves your advertising columns will prove ; but, not having received an offer for same, they were compelled to engage two professional operators, with assistants. That the studio is run by amateurs is a report put about by Mr. Freke for his own ends.

This gentleman has been a dealer in similar monopolies, having, to my knowledge, bought the sole photographic rights at two previous Exhibitions held in Cardiff. These facts he should have borne in mind before rushing into print. Moreover, he signified his intention of making a bid for the one under discussion, and was waited upon the day before the date upon which tenders were advertised to close. He preferred, however, to play a waiting game, and when, a month later, he wished to treat, he found he had waited too long, and that other arrangements had been made ; hence the heartburn.

The only way in which the name of the Cardiff Photographic Society has been used is in connexion with the Exhibition of Photographs in the Art Galleries, which is calculated to do the Society an immense amount of good locally and should largely increase the membership. The Society participates in the profits of the concession, if any, but contributes nothing ; and, if it results in a loss, this will be borne by the few who have had to do the work and advance the money.—I am, yours, &c.,

Cardiff, June 3, 1896. T. H. Faulks,
Hon. Secretary Cardiff Photographic Society.

Answers to Correspondents.

*** *All matters intended for the text portion of this* Journal, *including queries, must be addressed to* "The Editors, The British Journal of Photography," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* Henry Greenwood & Co., 2, *York-street, Covent Garden, London.*

Photograph Registered :—

Henry Goldsmith, Hay Cottage, Glen Aldyn, Ramsey, Isle of Man.—*Photograph interior of mud cottage, Jurby East, owned and lived in by William Corlett's Croit E-Grianey.*

Double Exposure.—C. Vennard. Evidently the plate has been exposed twice.

BROWN TONES.—A. M. The prints referred to are, for the most part, in carbon. If not, on specially prepared (by the users) silver paper.

PHOTOGRAPHING ON THE RHINE.—GERMAN TOURIST. So far as we are aware, there are no restrictions with regard to photographing the scenery on the Rhine, so long as you are not in the neighbourhood of fortifications or military stations or works. Be very careful on this point, or you may find yourself in trouble.

VIGNETTE MASKS.—Sensitise thin paper, and then print, shading those portions in proportion as the graduation is required. When fixed, they need not be toned; immerse in melted paraffin, and iron off with a hot laundry iron between blotting-paper. These papers are sold so cheaply that you will find it more economical to purchase than to make them.

CAMERA BELLOWS.—G. B. M. says: "I have a large camera with cloth bellows which has become spoilt by innumerable holes. Could you tell me if I could remedy this in any way; or, if that is impossible, give me the name of some one in London who would replace the defective one with a new bellows?"—There is no remedy but a new bellows, and that any camera-maker will supply.

PHOTOGRAPHIC APPARATUS ON THE HIRE SYSTEM.—EAST DEVON says: "Would you kindly tell me if there is a firm of photographic dealers who supply things on the hire-purchase system? I saw the address in THE BRITISH JOURNAL OF PHOTOGRAPHY some time ago, but cannot find it now."—We do not know the address. Possibly some of our readers may be able to supply it.

SUGGESTED FADING OF BROMIDE PRINTS.—C. VANDYCK. We should scarcely characterise the pictures as having "faded." The whites appear to be slightly degraded, which probably has arisen from prolonged exposure to light or "age," as you suggest; but the pictures are in such a good condition that we cannot imagine why the Sydney photographer failed to obtain a good result from them. Always glad to be of service.

FERROTYPE.—R. WADE. There is very little surprise that you have failed in getting good results. Sixty grains of nitrate of silver to the ounce of water for the sensitising bath could lead to nothing but failure. You are quite wrong in supposing that, by increasing the strength of the bath, you will obtain greater whiteness in the image. Thirty to thirty-five grains to the ounce is quite strong enough for a ferrotype bath; some use a weaker one than that.

SITUATION IN PARIS.—NEMO says: "I am desirous of obtaining a situation in Paris. Could you tell me the name and address of the paper for France corresponding to THE BRITISH JOURNAL OF PHOTOGRAPHY of England, and whether the average money is as good there as here, also the day the paper is published?"—We fear we cannot help you. However, you might address *L'Amateur Photographe*, 21, Boulevard St. Germain, Paris; or *Le Moniteur de la Photographie*, 55, Quai des Grands Augustins, Paris.

COLOUR FOR STUDIO.—BLINDS says: "I should feel obliged if you would advise me on the following: What colour blinds for north lighted studio for all-round work? What colour walls and woodwork? From ridge to eave is matchboards, then plastered wall, and matchboard dado. Would light staining and varnishing do for woodwork or floor, or would it reflect too much?"—Light green or dark blue will do quite well for the blinds, or even unbleached calico may be used, but the former will look best. A dark French grey will be a good colour for the walls, but anything like a varnished or glossy reflecting surface should be avoided.

RESIDUES.—HYPO BATHS says: "I have about a dozen gallons of old fixing baths I am desirous of converting into cash, and should be obliged if you can give me an idea as to the quantity of liver of sulphur required to precipitate silver. Also would you advise treating bulk in barrel or in separate vessels, a gallon or two at a time? In any instructions I have seen, no idea of quantities has been given."—The quantity of liver of sulphur, of course, is dependent upon the amount of silver there is in the solution. Add the liver of sulphur till no more turbidity is produced, after the solution has stood a few hours, by a further addition. It matters not whether the solution is treated in bulk or piecemeal.

OBTAINING PATENT.—PATENT asks: "Will you please inform me through your 'Answers to Correspondents' which is the safest and cheapest way for any one in the country to obtain a patent, and who would be the best agent to get a patent connected with photographic apparatus, and what would be the cost?"—The safest way is to put the matter in a respectable and old-established patent agent's hands. The cost then will be, for the term of four years, about twelve or fourteen pounds. If our correspondent does the work himself, the Government fees for four years are four pounds; a provisional protection for twelve months, one pound. If the invention is of any value, we should advise the employment of a patent agent.

WASHING PRINTS.—J. B. C. writes thus: "Is it to be inferred from your report of the proceedings of the London and Provincial Photographic Association and the paper by Messrs. Haddon & Grundy that thirty minutes' washing in a Wood's or other running water automatic washer is amply sufficient for P.O.P. prints after fixing, and that the same suffices for bromide prints and for negatives on film, that the presence of alum would not affect the thorough washing in the above time?"—Messrs. Haddon & Grundy's experiments were made with albumen paper, and not with gelatine, also the paper was fixed in a twenty per cent. solution of hyposulphite of soda for twenty minutes. Further, the paper was kept in motion by hand all the time it was in the hyposulphite and also in the washing waters. Their experiments cannot be taken as applying to gelatine prints and negatives. That would require further experiment.

SENSITISING PAPER.—MOTTLED says: "I. I am at present troubled by my sensitised paper going mottled. It goes this way whilst pinned up to dry, after being taken off the nitrate bath, which I keep up to about seventy per cent. I enclose you a small piece which I have just done, and which is hardly as bad as I have had it. It seems to me as if the paper was greasy. I do not think it is the fault of the bath. If you can solve this question for me, I shall be ever so much obliged. 2. I wish to evaporate the nitrate bath down. I have got a dish and stove suitable. Will you kindly tell me how to proceed when I have evaporated all the liquid away, so as to make the bath up again?"—If our correspondent is using his silver bath at seventy per cent. strength, we are not at all surprised he does not get on satisfactorily. We presume, however, that he really means seventy grains to the ounce. A little alcohol in the silver solution will sometimes get over the greasiness. If not, the paper must be blotted off with pure blotting-paper. 2. Evaporate the solution to dryness and weigh the crystals, then dissolve in the proportion desired.

DEPOSIT ON NEGATIVE.—BEGINNER says: "Will you kindly inform me, through the medium of the JOURNAL—1. What is the cause of the white deposit on the film of the negative herewith? 2. Can it be cured, and how? 3. How it can be prevented? The plate is Ilford special rapid; developer, hydroquinone. The plate, after development, was immersed for about ten minutes in a saturated solution of alum, and then fixed in the usual way. It was then washed in a zinc bath with running water from the tap, by means of an indiarubber tube, for a full two hours. The deposit appeared after drying. This is the worst of four plates, one of which is quite free, although, as far as I know, they were all treated in the same manner. Is there any publication which describes the working of the various kinds of hand cameras and the advantages of each?"—In reply: 1. You evidently did not wash the negative sufficiently after its immersion in the alum bath. Plain water and a little friction has removed the deposit on the negative sent. The remedy, therefore, is obvious. 2. Not that we know of. A copy of the ALMANAC contains mention (in the advertisement pages) of most types of hand cameras extant.

CONVENTION. LENS. STUDIO.—STUDIO puts the following queries: "1. Please give address of proper person to apply to. I want to be present at the Leeds Photographic Convention. What is the subscription? 2. Would a Ross's cabinet lens, worked at *f*-11, give as good a group photograph as a Ross's extra-rapid universal symmetrical at *f*-11? The latter lens is 9×7 for studio work. 3. What is the best type of lens (Ross's or Dallmeyer preferred) for general work in studio, 8½×6½, must be as rapid as their cabinet series? 4. How can I repair some large papier-mâché trays? They are coming uncemented at corners, *i.e.*, the different thicknesses of boards are separating, and forming four separate boards, instead of one solid piece. Could I fasten them by screws or rivets, and then cement over again? How can I make the very hard black paint or varnish these trays are painted with? 5. Is it possible to produce *first-class* results in a studio of the following descriptions: side-light of studio, 10×9 ft.; top-light of studio, 10×12 ft.? At south side there is another high building. If you can give me any help—what is the best plan of blind arrangements, and best position for sitter?—I should be very thankful."—In reply: 1. Mr. R. P. Drage, 95, Blenheim-crescent, W. The subscription is five shillings annually. 2. Practically, yes; if both lenses be of the same focal length. 3. If the lens must be as rapid as the cabinet lens, there is no better form than that. 4. Evidently the trays are worn out. Perhaps they may be patched up with marine glue. Papier-mâché goods are japanned. 5. Yes, very good results. But we should advise you to continue the glass right up to the building on the east side of the studio, and put the dark room at the middle of the south side. You can then have the sitter at either end, according to the light at the time. Ordinary unbleached calico for the blinds.

FRILLING FILMS.—COLONEL GUBBINS writes: "I am an old amateur photographer, but I am quite nonplussed. I have recently returned from a trip to Italy (Milan, Verona, Venice, Ravenna), where I did a good deal of work, using films. They were the remains of what I got two years ago. When I came to develop them, I was disgusted at the way they frilled. Two came off the celluloid altogether, only about two or three of those that I have developed have not frilled badly. With one I made a small leaden trough, three-quarters of an inch by half an inch and one inch longer than the film, put beeswax into it, heated till the wax was melted, and, in the dark room, dipped all four edges of the film into the melted wax. There was no frilling in this case, but I would sooner work with some other make than have that bother with each. I had *permessos* to take the interiors of several churches, a condition of granting a *permesso* being that I was to send three prints from each negative to the authorities. Can you tell me of any way of preventing the films from frilling? Would alum before developing affect the development? As in every case, except one, which could be explained, the frilling commenced at, and worked inwards from, the edge, it appears to me (1) that my size (7½×5) is got by cutting up larger ones after they have been coated; (2) that the coating is torn and lifted from the support either from carelessness in cutting up or from the cutter being blunt. If you can help me to get over my difficulty, you will greatly oblige."—We do not altogether like the idea of alum before developing, though that would, doubtless, be a preventive. As the waxing operation prevents the frilling, and is perfectly safe, we should be inclined to adopt that. We have, when we have had plates that frilled badly, rubbed the edges round with a paraffin candle, and then, after development, alumed the plate before fixing. That has proved a cure. It is possible that the cause may be as suggested.

*** Several answers to correspondents unavoidably held over.

EX CATHEDRÂ.

The unfavourable comments we recently passed on the quality of the lantern slides of Buluwayo scenes and incidents that were exhibited at the Alhambra Theatre of Varieties induced a well-known lantern-slide artist to write to the management informing them that he was open to undertake orders for the production of optical lantern slides of "first-class quality only." This gave Mr. Moul, the General Manager, the opportunity for a peculiarly happy reply, which we append.

* * *

"Whilst not prepared to give you an order," writes Mr. Moul, "I can suggest to you going out to South Africa or the Soudan, and endeavouring to obtain pictures from subjects of equally vivid interest to those exhibited by me here at the Alhambra. Under the conditions which you will probably find compulsory, you may discover it fairly difficult to get what you term 'slides of first-class quality only.' Should you, however, undertake such an expedition, and be fortunate enough to obtain such subjects as I have exhibited, and as well taken and in equally good condition, I shall be only too pleased to consider the exhibition of them at the Alhambra when you have them ready to propose to me."

Mr. Moul is, of course, entitled to make the most of the difficult conditions under which the Buluwayo photographs were obtained, for which nobody would be readier than photographers to make allowances; but we fear that the public, which pays its money to be entertained and amused, does not trouble itself much about the technical difficulties that have to be contended with in the production of photographs, or other parts of the programme, so long as it is satisfied with what it pays to see and hear. However, we hope that the next photographs shown at the Alhambra will be better than those we are now referring to, although, if we might tender a bit of advice to the management, it will probably be more to the taste of its audiences if lantern-slide entertainments are not included in the programme. We do not think that kind of thing is wanted in Leicester-square.

* * *

One of the features of the Speaight Studio in Regent-street, which we recently visited, is perhaps sufficiently novel to merit special reference. Messrs. Speaight intend devoting particular attention to theatrical portraiture, and to that end have provided facilities in their studio for the employment of a system of lighting which will impart to the photographs of stage ladies a footlight effect, intended to convey the appearance of the photographs having actually been taken in the theatre.

* * *

We observe with regret the announcement of the death of Colonel V. M. Wilcox, President of the E. & H. T. Anthony Co., of New York. Colonel Wilcox joined the firm about thirty years ago, and became successively partner, secretary, vice-president, and president. He was much esteemed by a large circle of business and private friends.

* * *

The many inquiries regarding postage-stamp portraits that are just now being sent us induce us to refer to some very good specimens of this kind of work that come from Mr. Alfred Pumphrey, of 62, Stanhope-street, Birmingham. They are supplied in gummed sheets, fifteen copies being made of the original on a quarter-plate, and the prices for prints and negatives are moderate.

* * *

A suggestion for overcoming the cockling tendency of mounted gelatino-chloride prints reaches us from Mr. A.

Martin, photographer, Wanganui, New Zealand. Mr. Martin places the mounted prints in long grooved frames to dry. This imparts some degree of convexity to the photographs, which, when taken out of the frame, are quite flat, owing to their natural inclination to cockle being overcome by their having been well bent back. The hint may be of use to some of our readers. The frames, according to a photograph Mr. Martin sends us, are simply long grooved parallel bars, joined together at the ends.

* * *

The value placed upon the services of professional photographers by some commercial firms is well illustrated by the copy of a correspondence which has been placed in our hands by Mr. Henry Hill, photographer, of New Brompton, Kent. A few days ago he was written to and asked his price for a negative of a set of engines and vertical boiler that he happened to have. He answered that his price for the negative (a cabinet-sized one) was 7*s.* 6*d.*, upon which he was informed that the price he was asking was "simply absurd," and that 2*s.* 6*d.* was "plenty" for the negative, an offer which Mr. Hill declined. We presume that the offer of 2*s.* 6*d.* was meant to include the right of reproduction, but, in any case, it cannot be said to err on the side of munificence.

CROSS-LINE *VERSUS* CHESS-BOARD SCREENS.

Inquiries are constantly reaching us with regard to the "chess-board" screen for half-tone work, for which a patent was taken out by Mr. Deville, Surveyor-General for Canada. As its name implies, this is a screen composed of alternate transparent and opaque squares arranged chess-board fashion; but, up to the present time, we have not seen any of the results produced by its means, nor are we aware of any one having used it on this side.

At first sight it might be set down as only one more on the long list of whimsical variations from the ordinary cross-line screen, and yet, on looking more closely into it, it seems to present points of difference from the latter that would stamp it as a distinct and useful departure, although, on following these up still more closely, we are left in doubt as to whether, in practice, it will be found to behave in any essentially different manner from the cross-line, or perhaps even whether it is not a retrograde step. Let us briefly examine into the matter.

If we take an ordinary chess-board, composed of alternate black and white squares, we have what actually represents a greatly enlarged image of the half-tone screen so called; and, if we fill up the white squares in each alternate line, horizontal and vertical, we have a similarly enlarged representation of a cross-line screen, in which the opaque and transparent lines are of equal thickness. For purposes of comparison, we may take this form of cross-line screen, although in actual practice the screens are ruled in a variety of different ratios between black and white.

The first difference that strikes us is that, whereas in the chess-board screen each square, whether black or white, is bounded on every side by a square of the opposite character, those of the same character only touching at their *corners*, in the cross-line screen each white or transparent square is entirely surrounded on all sides, as well as at its corners, by an opaque zone equal in width to its own side. Instead, in fact, of its corners touching squares of the same character, as in the chess-board, these corner spaces are opaque, from which it will be seen that the first important point of difference is a more complete isolation of the transparent squares, and apparently a greater preponderance of black in opaque spaces.

In the chess-board obviously exactly half the space is opaque and the other half transparent; but, if we repeat the filling-in operation, by which we convert the chess-board into a cross-line screen, we shall find that we fill in just one half of the transparent squares, so that, whereas in the chess-board screen the ratio of black to white is 1 : 1, in the cross-line screen of equally ruled lines it is 3 : 1. This means, of course, that just twice as much light is arrested by the cross-line screen as by the chess-board, or, in other words, that, under similar conditions, the latter ought to work twice as quickly as the other. We shall see later on whether it actually does; but, if this were the only advantage to be gained, a similar result would accrue in the cross-line screen by making the opaque lines narrower.

The next, and perhaps a more important, point that must strike us is that, in a given area, the chess-board screen has just twice as many open spaces as the cross-line, or, in other words, in practice, the dots would be so much closer together, and therefore a proportionately finer grain would result. In actual figures, taking two screens in which the transparent spaces were equal, the result as regards mere fineness given by the chess-board screen would be similar to that yielded by a ruling of nearly one and a half times the number of lines to the inch. A chess-board screen of 120 squares to the inch would give the same number of dots in a given area as a ruled screen of 170 lines, and, *per contra*, to produce the same result as that obtained with a ruling of 120 lines, a chess-board screen of 85 squares would suffice.

To sum up what would seem to be the advantages of the chess-board screen, they may be put down as greater working rapidity, with finer grain, and perhaps a more equal distribution of the opaque and transparent spaces. How far these advantages can be sustained, we will now proceed to inquire.

First, in the matter of rapidity, we have already said that, if this were a real advantage, it can be easily attained in the cross-line screen by a narrower ruling of the black lines; but the fact that, in the Levy screens, the black lines are never less than two-thirds, and more frequently of equal thickness with the transparent, is, we think, sufficient proof that rapidity gained by simply increasing the amount of light passed is not an advantage. On the contrary, if we look at it from a different standpoint altogether, it seems probable that this feature in the chess-board, or, indeed, any form of screen, may be an actual disadvantage. Those who are familiar with the use of the screen know full well that the gradation, or half-tone, is obtained by the more or less complete closing up of the opaque dots formed by the light passing through the transparent openings in the screen. In the half-tones and shadows these dots remain detached and distinct, the aim being to get them graduated in size from the minutest points in the deep shadows until they touch and overlap in the high lights.

Now, in the chess-board screen the squares are already closed up by the corners, and present precisely the same appearance as the half-tones of a negative produced by means of the cross-lined screens. Granted, as it undoubtedly will be, that such a screen is capable, with suitable screen adjustment and size of stop, of rendering detached and isolated dots, it can only be by altering the conditions very materially from those that prevail with the cross-line screen, but more especially in the direction of using a smaller stop. This being the case, what

becomes of the increased rapidity of working? It is surely counterbalanced by the necessity for slowing down the lens, in order to avoid the too complete closing up of the high-light dots.

If the necessity for a decrease of the stop exists in connexion with the high lights, how much more will it be so for the shadows? The tendency will be, with the transparent openings in the screen so close together, for the high-light dots to close up with a much smaller stop than usual, the consequence of which will be that no detail will be obtainable in the shadows without a very long exposure with an inconveniently small stop, so that, in the long run, it is probable the chess-board screen will be found actually slower in working than a cross-line of ordinary ruling.

Turning to the question of fineness of dot, this can scarcely be claimed as an advantage, since it is a quality that is limited by the capabilities of the etcher and the printer. When extreme delicacy is required and can be utilised, it can be secured by using a fine ruling much more conveniently than by resorting to the chess-board screen, which, from its very nature, combines the opposite qualities of a fine and a coarse ruling, and, in the matter of the adjustment of the screen distance alone, it must prove vastly more difficult to manage than the ruled screen.

Lastly, we come to the apparently more uniform distribution of the black and white spaces, which would at first strike one as a valuable feature in connexion with the chess-board screen; but, in reality, this is purely imaginary, for the distribution of the transparent spaces, which is all that concerns us, is equally regular in the ruled as in the chess-board screen, only in the former they are separated by perfect zones of opacity instead of closing up at the corners, and it is this feature more than any other that gives to the cross-line screen what will, we think, prove in practice its superiority over its newer rival. It is this distinct isolation of the transparent spaces that allows scope for the influence of the screen to work, whether that influence depends upon diffraction or any other cause, and we think, after due trial, that the chess-board screen will be laid aside, as so many other fancies have been before it.

The Light of the Future.—This is what the gas engineers term the electric light, and they appear to be content that the term may be employed, as they contend that gas is the light of the present. At a recent meeting of the Incorporated Gas Institute the President put forth the opinion that gas was leaving electric light a long way behind. It appears that the capital invested in the latter is six millions odd compared with sixty-nine millions odd in gas companies, and, notwithstanding the immense boom which electric lighting has had, the output of electricity from the whole country did not reach one-half of the actual progressive increase of the gas companies.

Photography at the Pole.—The Arctic Expeditions are now well on their way. The yacht *Windward*, of the Jackson-Harmsworth Expedition, left St. Katharine's Dock on Tuesday, last week, to rejoin the party at Franz Josef Land. The *Windward* takes with her an immense stock of provisions and material. A telegram received on Saturday last says that the *Virgo*, with M. Andrée and others of the Balloon Expedition to the Pole on board, arrived the previous day at Tromsö from Gothenburg, and resumed their journey the following day. Photography is always to be made a feature of in Arctic expeditions, but, unfortunately, we see very little of the results. It is to be hoped that the various enterprises now *en route* will be able to show some good ones on their return home.

The "Greenwich Visitation."—This annual event, which dates back from the year 1712, brings into prominence the photographic work of the Observatory. A full account of the progress of the star catalogue is given, and from it we learn that it will contain, at the expenditure of a comparatively small cost, the positions of stars down to the eleventh magnitude to an extent ten times that of a well-known standard star atlas. Between two and three millions of stars will be included, seven years being considered the correct time to estimate for its full completion. The dome of the central octagon tower will be the home of the twenty-inch photographic telescope, the gift of Sir H. Thompson, which is now nearly finished, and may be seen at Sir Howard Grubb's works in Dublin.

Acetylene.—Such is the commercial importance of the "new gas" that a journal devoted to the development of acetylene has been brought out and is now published in Milan. The greater or less success of this illuminant is simply a question of cost of the calcium carbide from which it is made. One of the earliest expectations with regard to its possible future and usefulness was that it might be used to enrich ordinary coal gas of low illuminating power, which can be produced at a low rate, owing either to the inferior grade of coal that can be employed in its manufacture or to the larger amount that can be produced from a given quantity of coal when a large proportion of hydro-carbons is not needed to be present. To a certain extent these anticipations have been realised; but, with regard to water gas, which is largely used in some quarters, it is found that the use of acetylene leads to the loss of the illuminating power of the latter.

More Royal Photographers.—It is said that Prince Henry of Orleans is an enthusiastic photographer, and has quite an extensive collection of snap-shot photographs that he has secured on his travels. Photographs of tiger-hunting, we are told, figure largely amongst the collection. Our Royal family have always been enthusiastic in photography, from the Queen and the late Prince Consort downwards. The Princess of Wales is a votary of photography, and has her cameras, and the late Prince Henry of Battenburg had a well-appointed private dark room, adjoining the photographic studio, at Windsor Castle. A professional friend, a day or two ago, remarked to us, on the spread of amateur photography amongst fashionable society, that it meant ruin to professional photography. We do not take this pessimist view of the question, but we surmise it will not tend to its advancement as a business, or, at least, for the time being.

Pegamoid.—Under this name there is now being introduced into commerce a new substance which seems to combine in itself the respective virtues of leather, celluloid, waterproof varnish, and close grained wood. It is claimed that artificial leather made by its aid is superior to even real morocco, while American cloth and cheap leathers are entirely put out of court by the new substance, which is both waterproof and uncrackable; it will not chip off, nor spontaneously ignite, which are two qualities often characteristic of the materials named. It will do for covers of books and trunks, and may be used for maps and enamelled paper, and is very suitable for wall and ceiling papers, which can be easily washed and cleaned.

For this reason, if all that is claimed for it turns out to be realised, it should be of the highest value in photography. Dark-room papers and fittings, not to speak of cameras, hand or otherwise, should offer a very suitable field for its employment. We await, with considerable interest, some further account of its behaviour in actual use.

The Spy Scare Abroad.—Last week we called attention to the trouble that tourist photographers may find themselves in from the incautious use of the camera abroad. Even sketching sometimes gets the tourist into difficulties, as happened one morning last week at Metz. A party of British officers were visiting the battlefields of the Franco-Prussian war, and ascended the tower of the Cathedral,

and while there two of them commenced sketching. The military telephonic staff stationed in the tower noticed what they were doing, and at once communicated with the town commandant, with the result that they were forthwith arrested on suspicion of being spies. They were then taken from the guard-house to the chief police-office, where they were able to prove that there was no ground for the suspicion; they were then liberated, about midday. This occurrence, following quickly on that chronicled in our last issue, emphasises what was then said as to the caution that should be used when photographing on the Continent. It is only in France or Germany, however, that trouble is likely to arise, and there principally on the frontiers or in the neighbourhood of fortifications.

Extraordinary Prices for Pictures.—Some remarkably high prices for paintings were realised at auction sales last week—that is, high prices considering they were portrait subjects. At Robinson & Fisher's sale rooms on Wednesday, a picture of the Viscountess Clifden and her sister, by Romney, was sold for 10,500 guineas. The first bid was 1000 guineas, and then the bidding proceeded slowly till 5000 was reached. Then the competition became spirited between two bidders, when it was finally knocked down to Wertheimer for the sum just mentioned. At Christie's rooms, on Saturday, Sir Julian Goldsmid's pictures were sold, amongst which was *Dorothea, Lady Eden*, by Gainsborough, which sold for 5000 guineas; *Barbara, Countess of Coventry*, by Sir J. Reynolds 3800 guineas; *The Hon. Mary Moncton*, by the same artist, 7500 guineas; and *Mrs. Mathew*, also by Reynolds, 4000 guineas. A Romney *Mrs. Oliver* (*nee* Miss Shakespeare), *with a sleeping Babe on her Lap*, sold for 3100 guineas. The prices realised at these sales are amongst the highest reached for portrait subjects. The total amount of the last-named sale was a little over 67,000*l*.

Washing Prints and Negatives.—The report of the meeting of the London and Provincial Photographic Association, at which Messrs. Haddon and Grundy detailed their experience of the washing of albumen prints, has brought us several letters from some who evidently do not care for the trouble of print and negative washing, as to whether gelatine prints and negatives can be effectually washed, automatically, in, say, half an hour. *Albumen* prints can be effectually washed in that time under the conditions laid down by Messrs. Haddon and Grundy. It will be noted in the report that the paper was fixed in a *twenty per cent.* solution of hyposulphite of soda for *twenty minutes*. This is a very different condition of things from those that obtain in practice with gelatine papers when a weaker solution is used and a shorter immersion given, to say nothing of the difference between the thick film of gelatine and the thin one of albumen. But that is not the point entirely, it is the long immersion of the paper in the strong solution of hypo that is the factor in the case. Under these conditions the silver salts are completely dissolved by the hypo, and are then easily washed away by the water.

A Ladies' Night at the Royal Society.—The second *Soirée* of the season of this Society was held at Burlington House on Wednesday last week, and, notwithstanding the wretched weather, there was a large attendance of visitors. The subjects that proved most interesting to the ladies were photography and electricity, though some of the experiments in the latter were somewhat interfered with by the dampness of the atmosphere, consequent upon the heavy rain throughout the day. Of course there were experiments, galore, with the Röntgen X rays, and Messrs. Siemens Brothers showed a number of illustrations of electrical discharges *in vacuo*. It is needless to say that the stereoscopic photo-chromoscope was in high favour, particularly amongst the lady visitors. So also were the electric lantern exhibitions. The things shown at the Royal Society's *soirées* are always the latest novelties in science, but the *soirées* are only available to a select few. However, the Lords of the Committee of Council on Education have arranged for the public exhibition of a number of the objects shown at the *Soirée* in the Western Galleries of the Science Museum, South Kensington, where they can be seen by any one interested, and no doubt many of our readers are. The exhibition, it is arranged, will be open for about a fortnight, so that there is no time to be lost by those who intend to pay it a visit.

Recent Researches in Rontgen Rays.—The period of popular exposition is gradually giving way to scientific investigation, though it is still the case that no satisfactory theory is yet propounded as to the nature and source of the rays. Many improved forms of apparatus, principally in the shape of the Crookes' tube, are being brought forward, and a full account of them is given in a recent number of *La Nature*. The production of the rays is governed largely by the nature of the coil employed, and, above all, on the contact breaker. Unfortunately this is liable to constant disarrangement through the passage of the spark producing rapid destruction of the opposing platinum surfaces used, the result being the spark going askew, and thus leading to irregular action. M. Marcel Deprez has ingeniously avoided this difficulty by causing one of the contact points to rotate quickly, and thus render the passage of the spark uniform and even.

M. Masson, with the same object, causes the break to make action by a wheel containing a number of segments which bring about the making and interrupting of the current. Of course a separate electric arrangement is needed for this, and the expense of the installation is in consequence increased.

"It is difficult," says M. C. E. Guillaume in *La Nature*, "to give general indications as to the best length of spark to employ for working the tubes. This length depends, above all, on the tube, that is to say, the distance between the poles and the state of the vacuum, in a word, on the resistance of the interior of the tube."

How the Tiring of the Tube is Prevented.—When working with small sparks, the current from the cathode may be diverted by the use of a magnet which causes it to be deflected to any required direction and so utilise different parts of the glass. As Mr. Meslin has shown, the rays may actually be concentrated by means of a non-uniform magnetic field. M. Wood's method is alluded to with praise. The cathode in his form is suspended from a sort of pulley, so that, by moving the tube a little, the rays may be systematically diverted to different parts of the tube, and so the effect of "tire" obviated.

How to Test the Tube.—Using a focus tube of the Jackson form, MM. Joubert and Bertini Sans, of Montpellier, are credited with having devised a method which is almost a copy of that invented by Mr. Espin, and described some time ago in these columns. These gentlemen take a bundle of glass, or even metal, tubes, and pointing it endwise to the emitting surface of the glass, take a negative at the opposite end of the tubes. A series of circular discs will be shown, all varying in brightness, that where there is most action showing a denser circle, and thus the exact spot whence the rays issue at their best can be localised. All that is then needed is to use a diaphragm over the spot, and it may be made of any suitable shape according to the indications of the bundle of tubes negatives.

INTERNATIONAL PHOTOGRAPHIC COPYRIGHT.

There are two classes of persons to whom an elementary knowledge of the law of international copyright may prove useful—the large and increasing number of photographers, both professional and quasi-amateur, who regularly or occasionally produce photographs that possess a distinct commercial value, and the perhaps still larger number of people who buy photographs for business and other uses. To the one, such knowledge would ensure them the full benefits that should accrue by their works; to the other it would save the annoyance and expense consequent upon even unwitting infringements of

the copyright laws: but it is very doubtful whether any ordinary layman would feel inclined to undertake the labour necessary to disinter that knowledge from the tomb-like depths of the various Acts of Parliament, conventions, Orders in Council, and law reports in which it is contained.

It would be found upon search that the central point was the Berne Convention, the final ratifications of which were exchanged in that city on September 5, 1887, behind which were the International Copyright Act of 1886 and the Fine Arts Copyright Act of 1862, and in front was the Order in Council of November 28, 1887, while over all was spread the veil of the judicial decisions that interpreted the construction of these various enactments. The Convention was concluded between Great Britain, Germany, Belgium, Spain, France, and Switzerland, the Republic of Haiti and the Principality of Tunis: and by it those powers constituted themselves an International Copyright Union, taking power also to admit into the Union any other country that might thereafter accede to the Convention in writing, and reserving the right of withdrawing therefrom after giving one year's notice of their intention to do so. Their primary object was the common protection of the rights of authors of literary and artistic work, while subsidiary objects were the collection, arrangement, and publication of information as to such rights and their protection, and the making of arrangements for the convenient study of questions of general utility relating thereto. By a final protocol it was agreed that those countries of the Union which did not refuse the character of artistic works to photographs should admit them to the benefit of the Convention, but should not be bound to afford to the authors of such photographs any further protection than was accorded under their own internal laws. The protocol further declared it to be understood that the authorised photograph of a work of art which came within the definition given in the Convention should be given in *all* the countries of the Union legal protection for the same period as the principal artistic work itself enjoyed. The distinction thus drawn between the two classes of photographs should be carefully noticed. Put in non-legal terms, it comes to this: A photograph which claims to be of itself a work of art is only entitled under the Convention to protection in those countries where such a claim would be recognised and admitted under their own domestic legislation; but a photograph which is a reproduction of a copyright work of art—say, for example, of an original painting—would be protected in every country of the Union as fully and for as long a period as the principal right of reproduction of the work itself existed. Great Britain extends the benefits of artistic copyright fully and unreservedly to photographs; and so, equally or to a lesser degree, do France, Germany, and Switzerland.

The English Maker.

Thus far we have given the general principles. What, then, are the practical applications? The British Journal of Photography in February, 1895, contained a brief summary of the essential features of photographic copyright in this country, and from that it will be seen that the deposit of an official form, duly filled up, with the payment of certain very small fees (1*s.* or 5*s.*, according to circumstances), entitle the author of a photograph to copyright therein for the remainder of his natural life and for seven years after his death. Under the Berne Convention, such registration of his copyright here also entitles him, *ipso facto*, without any further formality, to rights in every country of the Union equal to those which each such country would have granted if such author had been a native thereof and had duly complied with the requirements of its internal laws. In other words, compliance by the author of an artistic work with the copyright laws of the country of origin of such work is equivalent to compliance with the requirements of the copyright laws of every country comprised in the International Copyright Union, and secures to the author rights and privileges equal to those granted to natives.

The Berne Convention also gave liberty for the accession thereto of the Powers on behalf not only of themselves, but also for all or any of their colonies or dependencies; and Great Britain, as well as France and Spain, took full advantage of this provision. The International Copyright Act of 1886 was passed for the purpose of enabling this country to accede to the Convention and to make it binding as part of the law of the land: and the Order in Council of November, 1887, made under the authority of that Act, expressly directed that as from December 6 of that year the Berne Convention should have effect throughout all the dominions of the empire.

The English Buyer.

The buyer is concerned in international copyright in exactly the converse direction of the maker—the one is anxious to secure his rights with their attendant benefits, while the other is naturally desirous of escaping from the liabilities which follow their infringement. In this country it is an infringement to make for sale, hire, exhibition, or distribution (though not for mere personal gratification), any copy, engraving, or reproduction, of a copyright photograph or the negative thereof by any means and in any size, and the penalty for so doing may reach to 10*l.* for each copy, with power of imprisonment in default of payment. By the Convention, the foreign owner of a copyright photograph becomes entitled here to precisely similar rights as the English owner of a copyright photograph registered under the Fine Arts Copyright Act of 1862; and therefore all buyers of foreign photographs, either at home or abroad, with the intention of copying or reproducing the same in any way for sale, hire, exhibition, or distribution, or any business purpose whatever, should be careful to ascertain whether they are actually copyright or not. If they are, the copyrights must be purchased, or a licence in writing for the use thereof, limited to the desired form or process if needful, must be obtained. In any case, the burden of ascertaining whether any photograph is copyright or not rests upon the buyer, and, although in this as in other countries notice of the fact is not required to be placed upon copyright photographs, ignorance of the fact will not prevent the destruction of the pirated copies, or be accepted as a defence to an action for penalties or for damages. It is also an infringement to import from abroad, or sell, publish, let on hire, exhibit, or distribute, without the consent of the proprietor, any copy or reproduction unlawfully made of a copyright photograph; but in such cases guilty knowledge is essential to a conviction. If that can be proved, the penalties are as before stated.

Ernest J. Richards.

LABORATORY NOTES AND NOTIONS.

Silver Waste and Residues.—Much has been written from time to time as to the best methods of recovering silver from the inevitable waste which occurs in the laboratory, whether of the manufacture of dry plates and sensitised papers or in the ordinary every-day practice of the amateur or professional photographer. The instructions given frequently involve a great deal of labour in precipitating, collecting, and drying, with the advice to send the results to the professional refiner for melting down, and ending with considerable dissatisfaction and disappointment at the final yield. In conversation with a dry-plate maker, I was somewhat surprised to find that even in a large factory this method was adopted, and that no attempt was made to reduce the residues and waste on the premises. The magnitude of the issue involved would be a surprise to an outsider, and evidently forms an important item in the profit-and-loss account of any firm doing a large trade in dry-plate or sensitised-paper making. In these days of keen competition, when makers are vieing with each other to produce the most rapid plate, the necessary cooking of the emulsion is pushed to a point perilously near the fogging stage, and accidents frequently happen, with the result that a whole batch, containing many pounds of silver nitrate in its manufacture, goes wrong, and is condemned as unfit for plate-making. A not inconsiderable leakage of silver also occurs in the first washing water of the emulsion, as well as in the various utensils in use in the laboratory itself. It will thus be readily understood that a perfect and simple system of waste-saving and reducing is a matter of considerable importance, both from the manufacturer's and consumer's point of view. In treating on this subject in the present article, I will not enter into the method of recovery by furnace. It is not every one who has a properly constructed furnace at hand, nor would such be a desirable addition to the factory or laboratory. There are other and equally efficacious methods, however, which I will describe, such as any one, with the simplest appliances, can readily recover his silver waste by, and utilise it for further work or experiment. The principal materials to be dealt

with are, first, emulsions, either gelatine, or collodion; second, prepared plates or paper; third, hypo fixing baths.

Emulsions.—In a condemned emulsion the quantity of silver is generally pretty accurately known, and therefore an emulsion forms a good test of the accuracy of the reducing process. As illustrating different methods of reducing, I will describe one or two carefully carried-out experiments I have recently gone through. A quantity of experimental emulsions, made by different formulæ, but each containing 20 grains silver nitrate or its equivalent in bromide to the ounce was taken and divided into portions of 20 fluid ounces. Each lot, therefore, contained 400 grains of silver nitrate in its formula for mixing.

The first thing to be done is obviously to get rid of the gelatine; and, fortunately, this is an easy thing to do. The emulsion is melted and put into a beaker or boiling flask of sufficient capacity, and two ounces of commercial sulphuric acid is added to it. Heat is then applied, and, when the liquid is near the boiling point, an ounce or so of common salt is added, a little at a time. The hydrochloric acid which is thus liberated in the emulsion quickly destroys the gelatine, and the silver bromide will be seen to separate as a coarse granular precipitate, which quickly subsides to the bottom of the vessel. When this takes place, remove from the fire or turn off the gas, and allow to settle completely, when the supernataut liquid may be poured away, and its place supplied by clean water. Again boil to get rid of all the gelatine, and decant, after allowing the silver to settle. To ensure purity of result, the washing should be repeated with several changes of cold water, but, from the coarse and heavy state of the silver, this is very quickly done.

The precipitate now consists of bromide of silver, with perhaps a trace of iodide and chloride. To reduce this to the metallic state is the next operation. For this purpose some finely granulated zinc, about half an ounce, was added, and very dilute sulphuric acid poured upon it. A gentle evolution of hydrogen gas at once commenced, and the white silver precipitate quickly changed to a black, dirty-looking powder. It was put aside for twenty-four hours, with occasional additions of sulphuric acid, until all the zinc was dissolved, when the resulting, muddy-looking product was well washed in water, and boiled at least once to get rid of all the zinc salts formed.

After allowing to settle and draining closely, nitric acid was added until no more of the silver would dissolve, and the resulting silver nitrate evaporated to dryness and weighed. There should have been 400 grains of silver nitrate; but, on weighing, there turned out to be only 280 grains, or a deficiency of 120 grains. This deficiency had to be looked for in the undissolved sediment, after treating with nitric acid. This was again treated with zinc and sulphuric acid, and then, after washing, with nitric acid, and a further yield of silver nitrate resulted, but still not satisfactory. The reducing was a third time resorted to, when the whole of the sediment dissolved in the acid, and 385 grains of silver nitrate altogether were obtained, but, as the operation was tedious and the result not what it should have been, the method was abandoned. Evidently the nascent hydrogen reduced the external portions of the granular silver molecules, but could not penetrate through them, and thus a considerable nucleus of unreduced bromide remained. Iron filings were substituted for the zinc in another trial and longer time allowed, but with no better result.

Another twenty ounces of emulsion was taken, and the gelatine got rid of in the same way as the last, and the precipitate well washed; but this time the reducing properties of sugar and alkali were employed. To the drained precipitate 10 ounces of water, 2 ounces of white sugar, and 1 ounce of soda hydrate were added, and the whole brought to brisk ebullition, which was maintained for thirty minutes. By that time the whole of the silver appeared to be reduced, and of a brownish black colour. After well washing, nitric acid was added, and heat applied until no more would dissolve. The solution was carefully collected from the residue, evaporated, and weighed, when there were found to be 365 grains of silver nitrate, showing a deficiency of thirty-five grains. This was a decided improvement, and a saving in time as well. The residue left undissolved was again boiled with sugar and alkali, when the whole of it was readily dissolved by the nitric acid with only a few grains' deficiency.

Silver Chloride.—I next tried a silver-chloride emulsion, which contained ten grains of silver nitrate to the ounce. The emulsion had been made for printing-out purposes, and contained both chloride and citrate of silver. The latter was first converted into a chloride by the addition of sufficient salt, and the gelatine destroyed as before. Twenty ounces were taken, and consequently 200 grains of silver nitrate should be looked for. On the addition of the sugar and soda hydrate, as described above, reduction commenced at once, even in the cold. By the time the liquid boiled all appeared to be complete, but ebullition was kept up for fifteen minutes. On washing and dissolving in nitric acid, the whole of it dissolved readily, leaving no sediment, and there was no loss of silver. On trying an experimental lot, consisting of three separate and weighed portions of 100 grains each of silver nitrate, precipitated as an iodide, a bromide, and a chloride, and treating each to the alkaline-sugar reducer, it was found that the chloride was reduced at once, the bromide took longer time, and was not so thoroughly reduced, whilst the iodide was scarcely affected.

To sum up, then, from these results, the easiest and best method of recovering silver from emulsions is to first destroy the gelatine and well wash the precipitate, then convert all into a chloride before attempting reduction. Very much time will be saved, and a better yield given by doing so. The method of doing this is very simple. Allow sufficient water to cover the precipitate, and, by means of a glass tube to the bottom of the vessel, pass into it a stream of chlorine gas, which may be readily generated in a small glass flask. The chlorine will be rapidly absorbed by the water, and will also at once displace both the iodine and bromine from their combination with the silver, and leave a pure chloride behind. The eye is sufficient test for the completion of the operation, for the colour of the silver chloride is pure white, whilst any bromide or iodide gives a more or less yellow colour to it. After washing, the whole may be at once reduced by sugar and soda hydrate, and, if carefully done, no sediment remains behind, and no loss of silver will be found. Even the furnace method will not equal this. A large quantity can be reduced as perfectly as a small, being only governed by the capacity of the boiling utensils, whilst the cost in material and time is very little.

Plates and Cuttings.—Frequently a batch of plates will be coated, and, after drying, will not prove satisfactory, either from fog, or frilling, or lack of density. I understand that, in this case, it is usual to boil off the emulsion, and recover the silver by subsidence, an operation unnecessarily slow and tedious. Spoilt plates should be first soaked in a strong solution of common salt, and then transferred to a bath of dilute sulphuric acid. The hydrochloric acid generated in the film will quickly loosen it from the glass, and it can be readily removed without melting. All can thus be gathered up and drained, when the same method of reduction to the metal and nitrate may be employed as with emulsion.

Collodion Emulsion.—This was treated differently to the gelatine, but was equally simple to reduce. As the object was to recover the ether as well as the silver, twenty ounces of collodio-bromide were placed in a boiling flask, which could be connected with a suitable condensing arrangement. The emulsion contained 300 grains of silver nitrate. Two ounces of soda hydrate were added to it, and also a solution of sugar made into a syrup with water. Precipitation at once took place, and the flask containing the collodion was placed in a water bath, and the temperature of which was gradually raised until the contents of flask were in gentle ebullition. Precaution was then taken, by lowering the gas, to allow of no increase of heat, otherwise boiling over would arise and serious results might ensue. With a little care, however, the operation is quite safe. In about half an hour all the ether had passed over, and the action was stopped. Water was added to the residue, which was now a pasty black mass, and brisk boiling carried on for another half hour, when the precipitate was washed as before, treated with chlorine-water, again boiled with sugar and alkali, and dissolved with nitric acid. The pyroxyline, of course, remained behind, and was treated to several digestions with water to extract all the silver. On weighing the resulting nitrate the whole of the silver was recovered.

Paper Residues.—These may be either collodio-chloride, P.O.P., or argentic bromide, and present considerably more difficulties in the way of reduction. Many of the printing-out papers have a preliminary coating of gelatine and barium sulphate, and this, with the large mass of organic matter in the shape of paper, gelatine, sizing, &c., even when reduced to ashes, makes a bulky mass with only a small proportion of silver present. In this case the best method of recovering the silver at home is to dissolve all out with a strong solution of hypo. This should then be treated with a plate of zinc scoured bright, or a number of strips of zinc would be better. After about twenty-four hours the whole of the silver will be precipitated as an impure metal, being contaminated with both zinc and sulphur. The adhering silver should be brushed off the zinc into the hypo, and allowed to settle, when the black mass should be thoroughly washed in several changes of water, then in weak sulphuric acid, and again in water. Then add the necessary amount of nitric acid, and bring to a boil over the gas. Now dilute with water, and again precipi-

tate with a solution of salt, when a pure chloride will be obtained, which may be readily reduced as before.

An experiment was tried which will serve as a hint to photographers generally, and perhaps draw attention to what must be an enormous waste all over the country. A dozen half-plates, some of which had been exposed and developed, but not fixed, were placed in salt and sulphuric-acid solution alternately, and the loosened films carefully collected, and treated as a sample of emulsion. On evaporating the resulting product, very nearly a drachm weight of silver nitrate was obtained. This would be equal to one and a half ounces of silver nitrate to the gross of half-plates, and yet how many photographers are there who go to the slight trouble of recovering this waste? Of course, if the plates were first passed through the fixing bath, this quantity of silver would not be obtained from them, and it must be looked for in the hypo.

Silver Nitrate.—A few words will, perhaps, be useful as to making the reduced silver into nitrate fit for use in photographic operations. It must be understood that the first solution will have a large excess of acid present, and most probably other impurities, which must be got rid of before it is available for use. This is done by evaporating the acid solution down to dryness, using a very gentle heat for the purpose, or loss will ensue from too violent ebullition of the concentrated solution. The safest way is to employ a water bath until the contents of the evaporating dish are quite dry; then remove from the water bath, and apply heat to the dish by placing over the Bunsen burner a piece of fine wire gauze, and on this the dish. On raising the temperature, a considerable quantity of vapour of nitric acid will be given off, and, finally, the nitrate will fuse and settle down to a clear-looking fluid; now remove from the gas and allow it to cool. In fusing, not only is the excess of acid driven off, but any organic impurity which may have accidentally got into it will be eliminated. When cold, a small quantity of water is added, and the solid, fused nitrate redissolved by heat, the solution filtered and crystallised in the ordinary way. If time will not permit of crystallising, it may be evaporated down again to dryness, and the silver nitrate will be found sufficiently pure for all purposes.

EDWIN BANKS.

OUTSIDE STUDIO WORK.

BETWEEN the ordinary routine of a daily practice in the studio where portraiture forms the chief bulk of the work that has to be accomplished, and that of the operator, who has to undertake work, here, there, and everywhere, of almost every description, there is, indeed, a very wide difference. In the one case the work may be said to assume a purely mechanical form, the successful accomplishment of which, although necessitating a fair amount of thought and attention, is conducted under circumstances of but little doubt as to the most successful method to adopt, both for comfort in working and the certainty of gaining successful results, and is, therefore, by no manner of means to be compared to the difficulties attendant upon an outside operator, who is frequently called upon to undertake work in all sorts of places and under the most trying circumstances.

With the latter it but seldom happens that everything necessary to successfully accomplish the work is forthcoming without recourse having to be had to numerous makeshift arrangements, or the devising of special means to permit of the work being undertaken with anything like fair prospects of success.

As a rule, the general public, within recent years, have come to look upon the practice of photography as a thing of such easy accomplishment, in all places and under all sorts of conditions, that in many instances, where previously it would have been deemed absolutely necessary to send particular articles to a studio for the purpose of having such photographed, now it is generally considered only necessary to send for the photographer, to attend at home or the place of business, as the case may be, and have the work accomplished on their premises instead, without any thought being given to the facilities that exist for the successful accomplishment of the job. No doubt, there are many instances, such as home portraiture, where good business may be done in this line; but, on the other hand, there are innumerable cases where such away-from-home working can only be accomplished under circumstances of great inconvenience and difficulty. Speaking generally, there are always a large number of fixtures, however, that never could be dealt with other than in the positions they occupy. To remove such to a studio would be simply impossible, hence they have to be photographed just where they stand, often under circumstances of great difficulty.

In this class may be mentioned panels, or other large pictures or portraits in galleries, so fixed as to preclude any possibility of photographing in situations other than they occupy. When such are found to be well lighted, the erection of a suitable staging or platform to work from will be the only obstacle to overcome.

It not unfrequently happens, however, that these panels or pictures are found to occupy such positions that a very poor amount of daylight is found to fall upon them, an amount quite inadequate to show up much of the fine detail that, as it were, lies buried out of sight.

It is in cases and under circumstances of these kinds that an outside operator requires all his experience to aid him in securing good results, by devising such means as will enable him to undertake the work by means of artificial light.

To accomplish such, a considerable amount of preparation in the way of stagings is often required, and especially is this the case when the objects are situated in what may be termed outlandish places.

Much of the comfort and success will depend upon the erection of a suitable platform or stage to work from, and a few shillings judiciously expended on such is never thrown away in the long run.

Of the particular form of artificial lighting to employ, much will depend upon the nature of the subject being dealt with. In cases where only a small area has to be illuminated, the employment of two or three good limelight jets will be found very convenient to use. They can be placed in any desired situations without much trouble. In cases where a large surface has to be lighted, such as the entire side of a room, perhaps there is nothing more convenient than a number of good paraffin lamps ranged at various heights and distances from each other. With a battery of eight of such lamps I have secured some exceedingly good results when working in difficult situations. The main factor is exposure. It is not likely any one will at the first attempt just strike the right thing in this respect, but a trial plate will soon lead to the correct timing of the plate.

Any one who has never worked with the aid of such lamps on large areas will be surprised at the amount of detail such a method of lighting yields. I have seen large maps, *i.e.*, some fifteen feet by seven, copied with the aid of paraffin lamps, in which the minutest detail was developed out, detail that was quite startling, and which was hardly apparent to the naked eye. The main factor is to give plenty of time to the plate and develop accordingly.

Lamps are a great boon to an operator when working away from his studio. There are, however, innumerable instances in which movable objects have to be dealt with as well as fixtures, and then comes into play the golden rule which should never be neglected when possible, viz., "Do your utmost to get such moved to a suitable position in the open air." Daylight, no doubt, is the photographer's best friend, and, whenever possible, should be employed in preference to any method of artificial lighting.

The photographing of pictures, for instance, having surfaces that yield trouble in reflection, I firmly believe can be dealt with better in the open air by means of a good diffused light than by any other means of lighting, and I should never hesitate to adopt this method of working whenever possible. It is not always possible, however, to get even movables away from the positions they are found to occupy, and here again comes in no small amount of trouble, necessitating at times a combination of daylight and artificial lighting that is seldom resorted to, and yet very excellent results are obtained by means of such contriving.

The employment of suitable backgrounds is a further point that needs attention. No doubt, in many instances, it is impossible to avoid entirely blocking out the entire surroundings when any one special object has to be dealt with; but, as a general rule, it will be found that more harmonious results are secured where the relief is obtained by means of a properly situated background, hence a few good plain sheets of various colours become an indispensable adjunct to an outside operator's impedimenta. The employment of such saves a lot of labour in blocking out, and well repays the extra labour in moving about the same.

T. N. ARMSTRONG.

DYES AND PIGMENTS IN PRACTICAL PHOTOGRAPHY.

I.

Introductory—Dyes and Pigments in Photographic Papers—Pigments for Carbon Tissue—Ceramic Pigments—Photographic Ray Filters—Dyes for Sensitive Films—Printing Processes in Dyes—Colours for Photographic Positives—Photo-mechanical Inks—Histological Stains—Conclusion.

Introductory.—Colours play so important a part in almost every department of modern photography that a knowledge of the be-

haviour of dyes and pigments is a necessary part of photographic education. Unfortunately, the number and variety of colouring matters now available have had the inevitable result of involving the whole question in such obscurity that the photographer who would know the nature of the materials which he uses day by day is, at the outset, bewildered at the mere mention of colouring materials.

Existing manuals treat the subject of pigments chiefly from the artist's point of view; but in photography there are so many other considerations, some of them of extreme delicacy, that it may be useful, in view of the rapidly extending employment of colours in photographic processes, to consider the subject purely from a photographic standpoint.

Such a treatment, if at all exhaustive, would extend far beyond the limits of even a moderate-sized text-book. The notes offered in the following articles, therefore, will be confined to a brief discussion of the more important considerations which should guide the photographer in the selection of suitable colouring matters in the various branches of his art. For the purpose of greater clearness, the subject will be treated under the separate headings suggested by the different branches of photographic routine. Thus, in the first place, the theory and practice of dyes and pigments in photographic papers will be discussed; then will follow remarks on the pigments used for carbon tissue, ceramic pigments, colours for non-actinic media or ray filters, dyes and pigments useful for dry-plate processes, printing processes in dyes, colours for photographic positives, pigments used in photo-mechanical inks, and histological stains suitable for photo-micrography.

Dyes and Pigments in Photographic Papers.—The chief points to be considered in this case are the permanency of the colour and its possible action on the permanency of the photograph. A great many tinted albumen and gelatine printing papers are undoubtedly dyed with fugitive aniline colours, which rapidly deteriorate when exposed to sunlight. There is less excuse for the use of these dyes now that the more permanent madder colours are to be obtained so cheaply. A simple test for the presence of fugitive colours is based on the assumption that a tint which is rapidly destroyed by light will also be quickly bleached by chemical agents. A small piece of the paper to be tested, therefore, is placed in a dilute solution of bleaching powder, made by dissolving two ounces of the salt in one pint of water and filtering. It is better to control the result by comparison with another piece of paper dyed to the same depth with a fugitive aniline dye. Many photographers may prefer to tint their silver prints after finishing, as then any desired parts, such as the high lights, may be protected from the action of the dye by coating them with collodion or by touching them with a sable pencil dipped in melted wax. The staining can then be done to any required tint. Rich tints are got by successively treating the print with pink madder and Bismark brown solutions. A warm orange tint can be got by using an alcoholic solution of aloes, followed after washing by a bath of dilute ammonia.

In connexion with this subject it may be mentioned that it is an erroneous idea that all aniline dyes are unstable in sunlight. It is true that many of the older dyes of the magenta type are very fugitive, but others, such as the triphenylmethane group, are very permanent.

We come now to the question of coloured mounts used as a support for silver prints. Dark-coloured buff and brown cards very often contain iron compounds. In some specimens water alone will abstract enough iron to give a distinct blue reaction with ferrocyanide solution. The reaction of the paste, which often contains both common salt and an acid, may easily lead to the formation of enough ferric chloride to be most fatal to the permanence of a silver print. Acid mountants should therefore be avoided in the presence of iron compounds. The nature of the pigment in brown mounts may often be determined by soaking the card in water until a sufficient quantity of the pigment drops off as an ochry deposit. This can then be tested for iron by dissolving in hydrochloric acid and adding a drop of sulphocyanide solution, a red colouration denoting iron. Yellow mounts generally contain chrome yellow, a chromate of lead which appears to be quite harmless.

No less important in its reaction on the silver print is the presence of sulphide in the mount. This substance may be present either as a pigment or as the reduction product of a sulphate used as a loading for the paper. The most likely source of this trouble is ultramarine, which contains sodium sulphide, and is often added to paper pulp to secure a pure cold white. It is also a frequent constituent of some green and blue cards. A simple test for ultramarine is to burn the card until all the carbon is consumed, and examine the ash under a magnifying glass for any blue particles, which will be easily distinguishable, both by their colour and by their bleaching on addition of a drop of hydrochloric acid. Any card containing sulphide will show a brown stain if a drop of silver nitrate is placed upon it in the dark. The reduction of sulphate to sulphide may easily occur in the presence of damp organic matter. The white pigment used as loading is generally either calcium sulphate or barium sulphate, of which the former is especially liable to reduction, either to sulphite or sulphide, either of which is very undesirable in the presence of an acid mountant.

Sometimes the pigment used for coloured mounts is of too soluble a nature, and, when pressed in contact with a damp photograph, stains the print. This fault has been noticed in some dark chocolate mounts, but may be readily detected by soaking the suspected mount in water and pressing upon it a piece of white paper.

In addition to the above-mentioned dangers which lurk in certain tinted mounts, a source of even greater trouble is to be found in the bronze powder so often used for the edges. These powders adhere very loosely, and particles, getting detached, readily fall upon the surface of the card. Pure gold leaf would, of course, be harmless, but gold bronzes are often used, which consist of mixtures of copper and zinc. The cheapest mounts are frequently bronzed with aurum musivum, an unstable sulphide of tin, most pernicious to silver prints. A simple test for the nature of the bronze powder is a drop of nitric acid, which at once dissolves metallic bronzes, but does not attack the stannous sulphide. The latter, on the other hand, is dissolved by alkaline solutions, which do not affect the metal bronzes. Pure gold leaf is at once distinguished from metal bronzes by the absence of any action with a drop of nitrate of silver solution. The instability of inferior bronzes is an important consideration also in the selection of gold and silver papers to be used as a support for collodion transfers in reproductions of weapons, armour, or medals.

Hitherto attention has been called only to the influence of those colouring matters which have been intentionally added to the paper for the purpose of securing effects; but photographers have also to contend against other more insidious evils arising from the methods employed in the manufacture of the paper and cards which they use. In the first place the pulp is naturally more or less coloured from the impurities in the ingredients used in its manufacture. To produce pure white paper it is necessary to bleach the pulp. This renders necessary the employment of an antichlor, which, until some short time ago, was almost invariably sodium thiosulphate. The outcry raised by the photographic press against the use of this substance has probably led to its abandonment, at least for photographic purposes. Many photographers, however, prefer to mount their productions upon cards made from unbleached pulp, with an enamelled surface of permanent white pigment.

The suitability of this white pigment depends chiefly upon its opacity or body, as it is technically called. Some white pigments, such as magnesia, transmit more light than they reflect, and are useless in the production of enamel papers; while one of the most opaque white substances known, lead carbonate, is not suitable as a photographic pigment on account of its tendency to darken by sulphurisation in an impure atmosphere. Baryta white, or barium sulphate, is a constituent of many enamel papers, either alone or in conjunction with either kaolin or plaster of Paris. All other white pigments in common use, with the exception of Chinese white, an oxide of zinc, contain variable proportions of lead compounds, and are therefore objectionable for photographic use. A substitute for white lead, which is claimed to have even a greater covering power than that substance, is made by precipitating a solution of zinc sulphate with a soluble sulphide. The resulting zinc sulphide is calcined and stirred at a red heat, and washed when still hot by cold water. The result is an oxysulphide of varying composition, which is not only non-poisonous but is unaffected by sulphuretted hydrogen.*

The question of enamel surface papers loaded with white pigment is of increasing importance in connexion with reproductions from process blocks, as the finest results can only be secured by the careful selection of a suitable paper. White pigments are also employed in the manufacture of artificial ivory surfaces, which can be made by mixing finely divided barium sulphate with gelatine or albumen, and compressing the mixtures into sheets, which are then dried and polished.

Intimately connected with the subject of colours in papers is the tendency to discolouration. Mr. Sawyer has said that the Autotype Company has found it practically impossible to find a paper which does not change its tint by age and exposure to light. This may be due to several causes.

In the first place, it is the practice of some paper-makers to

* Phipson, *British Association Reports*, Dublin, 1878.

correct a yellow pulp by the addition of an aniline dye, the subsequent fading of which obviously causes the yellowness to reappear. Another cause of discolouration is to be found in the use of certain vegetable fibres, such as esparto or wood pulp in the manufacture of paper. It is said that some foreign-made papers and mounts are especially liable to discolouration from this cause. The pulp from these sources is liable to contain portions of the incrusting matter of pine wood, which is well known to darken in sunlight. Rag papers seldom darken. It may be useful, therefore, to mention certain tests which have been proposed for the detection of this evil. The presence of the light-sensitive incrusting matter in paper may be recognised by immersion in an acid solution of commercial aniline, containing—

Aniline	2 ounces.
Hydrochloric acid	3 „
Water	1 pint.

On exposure to the air, a yellow tint appears in the presence of the objectionable substance. The characteristic tints which wood paper assumes with various reagents serve to distinguish it from rag papers. Thus, with orcine a dark red is produced, resorcine and phenol produce shades of green, and phloroglucine a blue violet tint.

The whole question of photographic paper is of the greatest interest and importance. In more than one instance a faulty paper has damaged the reputation of photographic processes for permanence and stability.

J. Vincent Elsden.

PHOTOGRAPHIC WORKERS AT WORK.

VI.—Messrs. B. J. Edwards at Hackney.

"A hive of photographic industry" is a term that possibly not inaptly describes the well-known establishment of Messrs. B. J. Edwards & Co., in The Grove, Hackney. Our pages for very many years past bear witness to the fact that Mr. Edwards is a man of considerable inventive ingenuity, and a couple of hours passed in his society prove handsomely corroborative of the fact.

"This" says Mr. Edwards to us, "is called 'my cupboard.'" We are standing in the private office, and from the said cupboard, whose spaciousness at once excites our envy, Mr. Edwards takes the camera for making photo-chromoscopic negatives that has recently been described in our columns. At first sight the instrument bears the appearance of an ordinary hand camera with a reflector on the top; closer inspection, however, reveals the fact, that, small as it appears, it gives facilities for the simultaneous exposure of the three-colour sensation negatives required by the process. Inclined to the axis of the lens are two silvered mirrors; the first surfaces reflect the images for two of the colour sensations in a vertical direction, dark slides for the plates and grooves for the colour screens being placed *in situ*, while the plate and screen for the third negative occupy the usual position at the rear of the camera. The apparatus, as our readers have already been informed, is adaptable for viewing the positives. The "cupboard" shelters many other evidences of industry which time did not allow us to examine closely.

With a glance at the well-filled and workmanlike workshop of Mr. Edwards, we pass to the laboratory, and in the intervals of a discussion on some aspects of the evergreen subject of development, we have leisure to note the ingenious method of speed-testing adopted for arriving at the sensitiveness of the plates. Another interesting room is that devoted to the preparation of the varnishes, developing, and other solutions, which apparently issue in large quantities from Messrs. Edwards's establishment.

The oft-times asked question as to whether albumen has received its death-blow again occurs to us when we arrive at a large room illuminated by a pale yellow light which is set aside for the flotation of albumenised paper. In answer to a question, we learn that a considerable demand still exists for this printing surface, and that Mr. Edwards includes himself among those, and they are not a few, who think that the manipulative advantages and the quality of the results yielded by albumen paper will assure it considerable use by photographers for a long time to come.

After an inspection of the glass-cleaning room, and other portions of the works, we ultimately find ourselves in the coating room, which is built underground. We have been in many plate-coating rooms, but never in one as "safe" on the score of illumination as that of Messrs. Edwards. The sources of light appear to be placed as far as possible from the emulsion and the coating machine; they consist of gas jets shielded by deep ruby chimneys. Remarking upon the extreme gloom of the coating room, we are informed that Snap-shot Isochromatic plates are to be coated; and, for our edification, a batch is coated, and we have occasion to note with what evenness the emulsion is placed on the glass by the well-known Edwards's coating machine, over twenty of which we incidentally learn are in use by plate-makers in various parts of the world. The coated plates, as is well known, travel on endless bands over water and under ice trays, and, by the time they reach the extremity of the machine, the emulsion is set and the plates are placed in racks for transport to the drying room.

Of late years a new department has been added to Messrs. Edwards's business, namely, the manufacture of light metal, double dark slides, and tripod stands, to both of which we have from time to time referred. The portions of the premises set apart for the evolution of these items of apparatus supply to any one of a mechanical turn of mind most interesting food for reflection.

The presses and tools for such an apparently simple piece of apparatus as a metal double dark slide have to be specially made, and cost, we learn, not without surprise, some hundreds of pounds. Both tinned steel and aluminium are employed for the parts, and to complete one frame no less than forty-three distinct mechanical movements are necessary. The plain sheet of metal is first of all given a certain irregular figure, and then a long series of patterns are employed to turn it into the shape and interrelationship it is to ultimately occupy. Some of these movements we were permitted to observe, and the amount of ingenuity brought to bear in the details of the construction surprised us. In like manner the light metal stands, to which we, only the other day made reference, enter the workshops, so to say, as plain sheets of metal, and are stamped into shape, jointed, enamelled, and finished under the one roof.

Mr. Edwards is confident that his three-colour camera, when it is commercially ready, will not present any great difficulty in working, and he is hopeful of being able to provide a process which will enable the three negatives to be utilised for colour-printing purposes on paper. We finally quit the Grove with the persuasion that the present position of the busy firm of B. J. Edwards & Co. is due to unremitting effort and hard work, which are the secrets of success.

A SIMULTANEOUS PRINTING AND TONING PROCESS.

This is the invention of Messrs. Paul Emil Schoenfelder & Emil Kehle, who state that its object is to provide a chemical compound or composition for the preparation of paper, especially glazed paper, porcelain, or any other suitable material, on which photographic prints are to be made from a negative plate, whereby the toning of the picture is accomplished simultaneously with the printing, and thus the subjecting of the print, after it is made, to a separate toning bath, is fully avoided.

The composition consists of the following ingredients, combined in the proportions stated, and which we will call stock or ground solutions, viz.:—

Stock Solution A.

Collodion.

Pyroxyline	300 grains.
Ether	1 pound.
Alcohol (absolute)	1 „

Stock Solution B.

Fifteen grains of chloride of a metal of the platina class, such as chloride of gold, of iridium, of rhodium, of osmium, of palladium, or of platinum,

Said fifteen grains of chloride being dissolved in half an ounce of alcohol (forty per cent.).

From the stock solution A one and a half ounces is thoroughly mixed with ten drops of stock solution B, and the following ingredients are added in the proportions stated, viz.:—

(*a.*) Three grains of an organic acid, such as citric acid (tartaric acid, formic acid, &c), which is dissolved before mixing with the other ingredients in three drops of alcohol.

(*b.*) Fifteen grains of nitrate of silver, or its equivalent, first dissolved in fifty drops of forty per cent. alcohol.

(*c.*) One and a half grains of a chloride—such as chloride of strontium, or of barium, or of zirconia—dissolved, before mixing with the other ingredients, in three drops of forty per cent. alcohol; and—

(*d*). Two drops of a softening chemical, such as glycerine or castor oil.

The above emulsion is applied to the surface of the material on which the picture or photograph is to be printed.

The surface must be thoroughly dried before using.

After the print has been made, it is given a bath in a solution of hyposulphite of soda, one part to fifteen parts of water, in which bath it remains until all superfluous chemicals have been removed from the picture (about five minutes), when it is taken out and thoroughly washed in clean water.

The picture is then ready for mounting, and does not require any additional toning, as the toning has been accomplished simultaneously with the printing, and it has a superior finish, that will not fade or turn yellow by being exposed to light.

In place of stock solution A, a solution can be used composed of gelatine one part and water three parts, in which case the ingredients mentioned under *a*, *b*, and *c* are dissolved in water instead of alcohol.

The claims are:—

1. A chemical composition to be used for preparing the surface of suitable material for photographic purposes, consisting of a chloride of metal of the platinum class, of nitrate of silver or its equivalent, a holding substance, and an organic acid, such as citric acid.

2. A chemical composition to be used for preparing the surface of suitable material for photographic prints, consisting of a salt of a metal of the platinum class, of nitrate of silver or its equivalent, a holding substance, such as collodion, an organic acid, such as citric acid, and glycerine or its equivalent.

3. A chemical composition to be used for preparing the surface of suitable material for photographic prints, consisting of a holding substance, such as collodion, a salt of a metal of the platinum class, of nitrate of silver or its equivalent, a chloride, such as chloride of strontium, a softening ingredient, such as glycerine, an organic acid, such as citric acid.

*** *In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* JOURNAL *useful and instructive.*

CLEANING OLD NEGATIVE GLASS. (To W. Howard).—If the negatives are not varnished, all that is necessary is to strip them in the ordinary way with weak hydrofluoric acid; this will remove the film, leaving the glass quite clean; if the negatives are varnished, the varnish must first be removed with methylated spirit. W. H. will also find that, if he has any quantity of plates, the films are well worth sending to the refiners for the sake of the silver left in the film.—W. T.

PORTRAIT MOUNTS.—F. H. writes from Cape Town: "Some years ago, when over in England, I came across a new size of photograph mount which I should like to introduce as a novelty; but I have forgotten what it was called. It was about the same length as a cabinet, but much narrower; similar in shape to, but smaller than, the imperial, boudoir, and panel shapes. Can you tell me if it is an article of commerce still?"—No doubt, the "Malvern" is the card referred to. If so, it can most likely be obtained of Marion & Co., or any of the principal dealers.

CLEANING OLD NEGATIVES.—In reply to W. Howard, I do not know that it is the best way, but the following is the method I always adopt for removing old gelatine films, and which I find the quickest and most convenient, as well as the cleanest, I have tried. Prepare a half-saturated solution of alum—that is to say, a saturated solution mixed with an equal volume of water, and add to it hydrochloric acid in the proportion of one drachm to each ounce. Have this in a deep dish, and immerse the plates, without previous wetting, for two or three minutes—more will do no harm. Take them out singly, and, if the fingers be at all tender, rinse off the acid first, and then commence at one corner and, with a sort of rolling, rubbing action, remove the film from the edges of the glass. When it is once well started, it may be peeled off with the greatest ease in an unbroken sheet, leaving the glass beautifully clean. Many plates will peel easily by simple immersion in water, but not all. The alum toughens the film, and the acid loosens it from the glass and renders all perfectly easy; and I have never found any plate, however developed, refuse to part with its film under this treatment.—SYNTAX.

GREEN FOG.—EDER EMULSION says: "I have been experimenting in emulsion-making and for simplicity, and under certain conditions prefer Eder's ammonia-nitrate process. All the text-books state that green fog depends upon the gelatine used. In my experiments I have used twenty different kinds of gelatine in all quantities and at all temperatures, and have never succeeded in getting a batch that does not give green fog with pyro-ammonia developers. I feel convinced that this process is used commercially in such a manner that green fog is avoided, and should be obliged for any hint that you or your readers could give to put me in the right way to avoid this defect."—Perhaps some of our readers experienced in emulsion-making can give the desired information.

CLEANING OLD NEGATIVE GLASS. (To W. Howard).—I find that some brands of plates are much more difficult to clean than others, but fancy that, as a rule, plates that have been coated with a rapid emulsion are the easiest to manage. Sandell plates are certainly the most difficult. A plate cannot be cleaned unless the film has had a long soaking. I find the best way is to put a number of plates in the developing sink, cover them with a hot and strong solution of washing soda and soap, and leave them all night. In the morning the films, in most cases, can be easily rubbed off with a piece of flannel, and any that will not yield to this treatment are not worth troubling about. Slight traces of gelatine will be left adhering to the glass, but they can be cleaned off with flannel and a little sapolio or sunlight soap. A final rinsing in dilute nitric acid is desirable.—C. WELBONNE PIPER.

CURIOUS EFFECT OF ALUM.—J. B. E. says: "Having run out of ordinary alum a few days ago, and having by me some crystals labelled 'iron alum,' I used some of these instead in making up a 'hardening' bath for some freshly developed negatives, as I was under the impression that all the alums possess the property of hardening gelatine. To my surprise, on treating the first negative, the image almost entirely disappeared, leaving nothing but a faint yellow stain where it had been. Needless to say, I did not repeat the experiment. The salt is something like ordinary alum, in the shape of crystals, but a brownish-red colour, and quite without smell. Can you give any explanation as to what it is?"—The salt is, no doubt, what it purports to be—iron alum. In this case, most probably the ammonia compound, the sulphate of iron and ammonia (ferric). Our correspondent is quite right with regard to its hardening properties upon gelatine, but he reckoned without its solvent action on metallic silver, which was the reason of the disappearance of the image.

REPRODUCING NEGATIVES.—I think the following plan will meet the requirements of J. Hastie. Select a good sample of Rives' albumenised paper and float it, reverse side downwards, on a fifty or sixty-grain bath for a somewhat longer time than would be necessary for ordinary purposes. For ordinary printing what is required is to keep the image as much as possible upon the surface of the albumen, in order to secure brilliancy, and for this purpose a short floating is best; but, for our present requirements, a better result accrues from the formation of the image in the body of the paper. Consequently the latter is floated on its back for a long enough period to draw the chloride from the albumen into the pores of the paper. Four or five minutes will usually be sufficient. The printing may be done upon either side of the paper, but if from the albumen side there will be scarcely any surface image. In any case, however, the printing must be judged by transmitted light, so that the surface image is of no importance. Print very deeply, until the highest lights are tinted, wash and fix in clean hypo without toning. The image *may* be toned, if that course be preferred; but it is a needless expenditure of gold. In that case the printing need not be carried quite so far. When fixed, wash well, dry, and, if rapidity of printing be desired, apply wax, oil, or vaseline, to the back of the print, which at this stage should appear on the surface hopelessly over-printed, but show a strong clear image by transparency. Now repeat the operation, using this print as the *cliché*, and the result will be a negative that is printable from either side, and, if properly done, will give proofs scarcely, if at all, inferior to the original.—SYNTAX.

Our Editorial Table.

Photographic Amusements.

By Walter E. Woodbury. New York: The Scovill & Adams Co.

Mr. Woodbury acknowledges his indebtedness to a variety of sources for the contents of this entertaining volume, which sets forth, so to say, the art and mystery of trick photography. Multi-photography, spirit photography, silhouettes, caricature photographs, distorted images, freak pictures by successive exposures, artificial mirages by photography, composite photographs, and "doubles," are only a few of the subjects dealt with. We can fairly say that the book well redeems its title, and supplies a fund of amusement in producing, to quote Mr. Woodbury, "a number of novel and curious effects that can be obtained by the aid of the camera." For all that, we beg to be allowed to demur to the inclusion of telephotography, lightning photography, instantaneous photography, direct positives in the camera by the thiosinamine process, and the hydrofluoric acid method of enlarging, in a volume avowedly compiled to entertain and amuse. They strike us as being uncommonly serious branches of photography. However, the book is very well illustrated, and, on that and other grounds, much may be forgiven it.

Sample Books of Carbon Tints.

Thomas Illingworth & Co., Willesden Junction.

Messrs. Illingworth send us a book of sample tints used as specimens for their carbon enlargements, which they are issuing to their customers. The prints, as such, are admirable examples of the process, and the idea of so issuing them is both good and novel.

The "Shashin-Sowa" Photographer's Pocket Book.

The Shashin-Sowa, Tokyo.

Our contemporary has issued a neat little pocket note book. Space is provided for photographic memoranda, and probably a great deal of information on photographic matters is given—in Japanese. However, there are occasional oases in the desert, for here and there we come across lists of chemicals, diaphragm numbers, and so forth, which warrant the assumption that the information is really and truly photographic. We welcome, even if we don't wholly understand, the latest photographic note book.

Exposure Tables for Photographers in India and the Far East.

By George Ewing. Calcutta: Thacker, Spink, & Co.

Mr. Ewing's contributions to our contemporary, *The Journal of the Photographic Society of India*, are always marked by undoubted practical knowledge; and he has evidently been at great pains in compiling the tables in this book. They are calculated for the various months between N. latitudes 30° and 23°, and for near the equator, and should be useful to eastern photographers, as they are obviously the outcome of much conscientious work.

Rouch's Eureka Hand Camera—Half-plate Size.

W. W. Rouch & Co., 161, Strand.

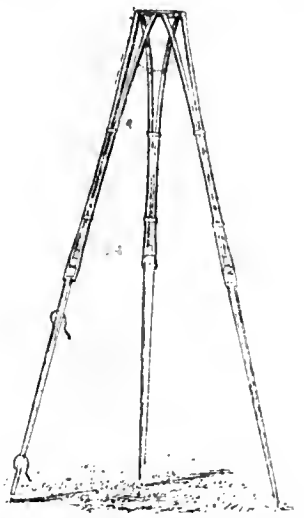
There evidently exists a demand for hand cameras constructed to carry plates larger than quarter-plate size, for Messrs. W. W. Rouch & Co. are introducing a half-plate hand camera on their well-known Eureka design, and have submitted it to us for inspection. When closed, its dimensions are $9 \times 7 \times 6$—a by no means large size. It is beautifully made in mahogany, and, if occasion arises, it can be used on a stand, as it takes dark slides and a focussing screen. Ordinarily, however, it is fitted with the firm's Eureka changing back, which has been favourably known for several years. The lens is a rectilinear of $7\frac{1}{2}$ inches focus, and a Thornton-Pickard time and instantaneous shutter is employed, the speed of which is regulated from underneath the camera, the speed dial showing on the top. The release is effected by pressure upon a metal pin, and two bright finders are fitted to the camera, which is focussed by means of a milled-head screw adjustment, a focussing scale being affixed to the side of the instrument. The half-plate Eureka has been in successful use for some time. It is a thoroughly useful and well-made instrument and deserves to be popular.

The Manx Stand.

The Sciopticon Company, 10, Highbury-quadrant, N.

Many of our older readers will learn, we are sure, with interest that the Sciopticon Company, of which the late George Smith (a name once very prominent and respected in photographic circles) was the moving spirit, are continuing the preparation and sale of the special productions for which it has been long noted. We observe, from the catalogue before us, that a lengthy list of slides by the incomparably beautiful Woodbury process is given, and that the Sciopticon lantern, the Woodbury photometer, and many other useful items are described.

The Manx tripod stand, here illustrated, has ever been a favourite with tourist photographers, and well merits that favour. Fully



opened, its height is 5 feet; closed, the measurement is 2 feet 8 inches, its weight being only $1\frac{1}{2}$ lbs. When drawn out, the brass holders (shown) secure it in position, and impart to it very great rigidity. Its lightness, rigidity, and simplicity of construction constitute the "Manx" stand an ideal addition to the apparatus of the tourist photographer.

Catalogues Received.

Louis Gandolfi, 752, Old Kent-road.

Mr. Gandolfi devotes himself to the manufacture of cameras and other items of photographic apparatus, which, from his list appear to be good and cheap.

Harrington & Co., 66, King-street, Sydney, N.S.W.

We do not remember to have seen before, a photographic dealer's catalogue from "down under," and, on turning over Messrs. Harrington's well-printed volume of 192 pages, we realise how much antipodean photography depends upon home products, most of the goods mentioned in the catalogue emanating from the old country. This, however, by the way. The catalogue contains much useful information on technical subjects, and in other respects is an excellent production, which is, doubtless, much appreciated by Australian photographers.

W. I. Chadwick, 2, St. Mary's-street, Manchester.

Mr. Chadwick's newest list is devoted to radiography, for which purpose illustrations and prices of coils, vacuum tubes, fluorescent screens, &c., are here set forth.

Newton & Co., 3, Fleet-street, E.C.

Messrs. Newton, as is well known, have specially addressed themselves to the supply of radiographic apparatus, and their list deals with tubes, coils, screens, and other requirements of the "new" photographer.

Ausführliches Handbuch der Photographie.

(2 Auflage. Siebentes Heft. II. Band, 2 Heft.)

Dr. Josef Maria Eder. Wilhelm Knapp, Halle-a-S.

This volume of Dr. Eder's complete guide to photography deals with the wet-collodion process in all its branches, including ferrotype and

the production of negatives for process work. It is characterised throughout by Dr. Eder's thoroughness and wide research. The book will be of especial value to the process-worker, giving, as it does, the scientific principles involved in the use of the screen and stops of different forms. Short practical rules are also given for their use.

Künstlerische Photographie.

By J. Raphaels. Ed. Liesegang, Düsseldorf.

This work may be compared to some extent with Dr. Emerson's noteworthy treatise on Naturalistic Photography, and may probably attain an analogous position in German photographic literature. The author's standard is, that a photograph, for other than scientific purposes, should give an impression to the eye similar to that produced by a copy of a true work of art. In other words, photographs should resemble photogravures of paintings of the highest order. The writer not only treats of the æsthetic side of the subject, but, in the second division, enters into the technical, and, unlike Dr. Emerson, recommends the photographer to avail himself of the many devices by which negatives and prints can be modified to suit the desired end. The book has for frontispiece Dr. Emerson's well-known picture, the East Anglian study of *Ploughing*.

Die Zinkätzung.

By Jacob Husnik. A. Hartleben, Vienna.

A second edition of this work has just been published, and the clear and systematic treatment of the subject cannot but add to the reputation of the author as a teacher and craftsman. The first part deals with the history of chemical engraving, and describes in a lucid manner the various processes involved in photo-zincography. The second part treats of the various tools and materials employed. In this edition the author includes descriptions of the different routing machines, which now play an important part in this branch of work. There are also some illustrations showing the capacity of zincography as a graphic art. It is a valuable guide and reference book to those engaged in this branch of photo-engraving.

News and Notes.

Royal Photographic Society.—Technical Meeting, Tuesday, June 23, at eight p.m. A *Practical Demonstration of Colour-screen Making and Testing*, by Mr. F. E. Ives.

Leytonstone Camera Club.—A Cycling Section having been formed in connexion with this Club, it has been decided to admit all persons joining as members on or before the annual general meeting, June 24, without entrance fee. Annual subscription 5*s*.

The Photographic Club.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, June 24. Subject for discussion, *Toning Silver Prints*. Visitors are always welcomed by the members.

The New Photography.—Tylar's light-tight bags are being supplied in large quantities, both to the professors at home and on the Continent, for containing plates and films for radiograph experiments. When used with a celluloid film, they can be bound round a limb, giving closer contact and better results.

The following are the awards in the competition for negatives on "Gem" Portrait Plates by professional photographers: 1st prize, Miss Gertrude Reston, The Studio, Stretford, Manchester; 2nd, G. E. Stone, 25, Farringdon-street, New Swindon; 3rd and 4th, divided between B. T. Ord, 38, Derwentwater-road, Gateshead, and W. Hillman, South-beach Studio, Pwllheli.

In a late paper in the *Comptes Rendus* on the products of combustion of an acetylene burner, and explosive mixtures of acetylene and air, M. M. Grehant states that the combustion of acetylene gas in an ordinary fishtail burner is complete, the products not comprising the least trace of a combustible gas containing carbon. With mixtures of acetylene and air, the most violent explosion was produced when the volume of air was nine times that of the acetylene.

"For nearly half a century," says the *Chemical News*, "there has been an active search for a true method of photography in colours—some process for obtaining at once, without any "hand-work" etching and the like can produce on the sensitive plate, the reproduction, *e.g.*, of a sunset sky in its natural colours, and which shall not be liable to fade. The very fact that, after thousands of experiments, we are little, if any, nearer the mark than in the days of Fox Talbot—the very fact of such prolonged failure is discouraging, and no less so are the attempts at obtaining coloured results in a roundabout and partially mechanical manner. Nevertheless, hope and effort should not be abandoned. Some day objects may be reproduced by a pure photo-chemical process, and we may then bow the hand work out of court."

At the Reception in aid of Guy's Hospital at the Imperial Institute, on Wednesday, June 10, a demonstration of the X rays was given by Mr. Le Conteur and Messrs. Houghton & Son, with apparatus supplied by the latter. A very successful negative was taken of the hand of H.R.H. the Prince of Wales, who took great interest in the apparatus, this being the first time he has seen a demonstration of the Röntgen rays. Messrs. Houghton & Son had five complete apparatus at work, and Mr. Joyce, of Oxford, Mr. Gray, and Mr. Martin were all present with apparatus.

"Dr. Baraduc has been describing, before the Paris Medical Society, his system of photographing thought. The images which he obtained," says the Paris correspondent of the *Daily Telegraph*, "are as vague as his theories, and give rise to a good deal of comic criticism. The erudite physician says that, by the aid of his hand or his forehead, he can project his thoughts or ideas on a photographic plate in the dark. The reproduced figures which he showed as the results of his experiments were clouds, dim human forms, a sort of cavern, and a heart, the latter being the iconographic outcome of the emotions experienced by the doctor, who is evidently pious, after he had been visiting the Church of the Sacré-Cœur at Montmartre. With the help of electricity, he also obtained other effects, but he maintains that this force is unnecessary when the person who wishes to project his thoughts on a plate is a being of potent imagination and resolution. Further explanations of the doctor's theory must be awaited before any judgment can be pronounced on the value of his thought pictures."

Hair Lines and Friction Marks on Bromide Paper.—We have lately several times had occasion to answer questions with regard to the removal of the fine hair lines and friction marks which occur on the surface of bromide papers, and especially of Nikko paper. These marks may be caused by the friction of one sheet over another when withdrawing them from a packet, or they may be caused by rubbing the finger or nail accidentally over the sensitive surface. The harder and more smooth this surface, the more easily are the marks produced. Fortunately their removal is a very simple matter, as they are entirely on the surface. The developed, fixed, alumed, and washed prints must be allowed to dry. Then soak a piece of cotton-wool in water (or methylated spirits, though this does not work quite so quickly), and squeeze it out. Proceed to wipe over the surface of the print with the damp cotton-wool firmly but not too roughly. Do not have your cotton-wool too wet, as this does not work so well. Finally wipe the whole surface over with a wet clean pad of cotton-wool. When dry, the prints will be found to be spotless and perfect.—*Kodak News*.

Many are the uses to which the Röntgen rays may be put. It has, however, been reserved for Miss Frances Willard, a bright and shining light of transatlantic temperance, to promise the eurolment of the X rays beneath the banner of militant teetotalism. One has heard, says the *Graphic*, of the Awful Warning, that is to say, the reclaimed drunkard who thrills a teetotal audience with the recital of his past alcoholic achievements. It seems that the Awful Warning will now have an even more favourable opportunity of working for the cause. It is proposed to utilise the X rays "for revealing the process of deterioration as it develops, drink by drink, in the drunkard's stomach." This should be, from the spectacular as well as from the scientific point of view, a very remarkable experiment, but it occurs to one that it will take rather a long time to perform. The process of deterioration as produced by a succession of single drinks, is not rapid, and the subject of the experiment will have to take a good many before he gets perceptibly "furtherer" in any sense of the term. Nevertheless, the Awful Warning will have an uncommonly good time; and it is pleasant to think that, if ever the Awful Warning succumbs to the effects of his zeal for temperance, there will be no lack of candidates for the reversion of his position in front of the camera.

"Ruling Diffraction Gratings.—'Rowland's grating' is made by ruling parallel lines on a concave plate of what is known as speculum metal. This metal," says *Appleton's Popular Science Monthly*, "is an alloy of two parts copper and one part tin. The parallel grooves are made with a delicately adjusted diamond point. The machine on which the grating was made was manufactured after eighteen months' hard work by Theodore C. Schneider, the machinist at Johns Hopkins University, from the designs of, and by processes invented by, Professor Rowland, who was constantly at hand to direct every movement. This machine is in a dark vault under the laboratory. When a 'grating' is being made, it runs night and day. The vault is locked, and no one is allowed to enter it, for the machine is so sensitive that the temperature of a human body would disarrange it. When a new diamond point is being tested, as is now the case, Professor Rowland will permit a few people to visit it. Sir William Thomson, the Earl of Rosse, Lord Rayleigh, Professor Ball, Astronomer Royal of Ireland, the late Professor Helmholtz, of Berlin, Professor Mascart, of Paris, and Professor Lemstrom, of Sweden, are among those to whom this courtesy has been extended. The motive power of the machine is an hydraulic engine. The water is kept at a constant height in a tank near the roof, to ensure unvarying speed. It is driven by a belt attached to a solid brass driving wheel on the machine. A crank is turned by the same on the other end of the shaft. This crank moves the carriage that conveys the diamond point back and forth over the surface of the 'grating' or plate. This carriage rests on two steel ways, which are flat on top and slanting slightly outward, so that there are three points on one way or rail on which the carriage rests. These 'ways' are ground so as to make them as nearly accurate as possible; but they cannot be made perfect, for Mr. Rowland tested them with a microscope and found that they were 'out'—that is, not exactly perfect—by one fifty-thousandth of an inch. He did not attempt to improve them."

Tesla's New Light.—The *Philadelphia Public Ledger*, of May 21, contains the following interesting item of news: It is announced that Nikola Tesla has solved the problem which he set before himself many years ago, and which may revolutionise the system of electric lighting. It is, electrical experts say, the nearest perfect adaptation of the great force of nature to the use of man. In Mr. Tesla's laboratory in Houston-street is a bulb not more than three inches

in length, which, when the current is turned into it, becomes a bulb of light. With it a very large room is so lighted that it is possible to read in any corner. Yet this is done without the attachments necessary in existing lights. The rays are so strong that the sharpest photographs may be taken by them. No new dynamo is required to produce the current. There is no danger of harmful shock in its use. Stories have come from time to time from Mr. Tesla's laboratory that he was experimenting on a light of this sort. Rumours of success and failure have followed each other, and Mr. Tesla's friends were inclined to doubt that he would succeed. A half dozen times the discovery was on his finger tips, only to elude him, but now he has told his friends of his success. Mr. Tesla has been working for many years on his theory of the necessity and practicability of the conversion of electricity. The present incandescent light gives only three per cent. of illuminating power; the other ninety-seven per cent. is wasted in heat. In accordance with his theories, which have been already applied successfully to the economical transmission of the electric fluid, he applied himself to the saving of some of this wasted energy in electric light. The bulb which he has perfected gives ten per cent. of light, and loses ninety per cent. of energy. Mr. Tesla declares that he will, with the aid of a few more experiments, be able to produce forty per cent. of light, so that the waste will be reduced to only sixty per cent., or thirty-seven per cent. less than at present. The principle of the light is vibration. The illumination is secured by means of what Mr. Tesla terms a vibrator within a bulb, which holds the vibrating needle within a vacuum. The needle vibrates so rapidly that the figures per second sound imaginary, but it is this intensity of energy which gives the light its brilliancy and its apparent steadiness. The lights do not have to be renewed.

PROPORTION, AS APPLIED TO ENLARGEMENT AND REDUCTION.—Professional photographers when giving orders for enlargements are not at all times sufficiently definite in their instructions to the enlarger to enable him to carry out their wishes exactly, and it is found out, when too late, that the result is not quite what was expected. Disappointment is often experienced through the inability of the photographer to sufficiently allow for the difference in the proportions of the original to the enlargement. For instance, an order for a 12×10 enlargement is given, to be made from a cabinet print, and all the subject is to be included. The order is executed and dispatched, when, forthwith, a complaint is made that the enlargement measures only 12×8¾ instead of 12×10, and it is, therefore, of no use, as it was wanted to go into a frame already made, having a mount with an opening 11×9. To prevent these disappointments, I purpose here to point out a way by which any one may know exactly what proportions any print or negative will have when enlarged. Suppose, for instance, it is required to enlarge a cabinet portrait to 12×10, proceed, first of all, to measure off the full size of the cabinet print (5½×4) on a piece of paper. Now draw a diagonal line from the left-hand bottom to the right-hand top corner, continuing the line for about 16 inches; then, from the left-hand bottom corner, continue the vertical line to exactly 12 inches high, and from this point draw another line at right angles till it meets the diagonal line; a measurement of this line will show the width given by the cabinet print when the height is enlarged to 12 inches, viz., 8¾ inches. This explanation may appear somewhat complicated, but it is in reality very simple, and is easily proved by following this example on paper. It applies to any size and proportion. In the *Photographic News Year-Book* for 1880 I gave a further application of this principle, which is illustrated. It is termed "A Measuring Mask;" the whole thing is very simple, and any one could make them with a few sheets of thin cardboard. The great advantage of these masks is, that the opening, when adjusted to the desired height, will, at a glance, show the true proportionate width that will be included in the enlargement. For cabinet-sized negatives the openings need not be larger than 6×5, which will, of course, answer as well as 12×10, and be more easily handled. It will be obvious that a mask will be required for sizes that do not bear the same proportion to 6×5. A mask, for instance, with an opening 10×8, will also suit for 15×12 and 20×16, as the relation in each case is as 5 is to 4. The proportion of 6 to 5 will suit for 12×10, and 18×15, and 24×20, because they are in the proportion of 6 to 5. It will thus be seen that a large number of masks will not be required to take all the usual sizes. In copying a painting, it is sometimes useful to know what the width of it will be when the base line is reduced to any given length. Stretch a thread diagonally across the picture from opposite corners. Mark the required base line, from the lowest end of diagonal, along the bottom edge of painting; then, with another piece of thread, with a weight at one end, plumb right over the mark. The point where the threads cross will always be the proportionate width.—H. J. BURTON, in *Autotype Notes*.

Patent News.

THE following applications for Patents were made between June 3 and June 10, 1896:—

APPARATUS.—No. 11,909. "Improvements in Photographic Apparatus." Complete specification. A. E. DEHNERT and K. H. G. HEDWIG.

LANTERNS.—No. 12,005. "Improvements in and relating to Magic Lanterns." R. EHRLICH.

SHUTTERS.—No. 12,048. "Improvements in Photographic Shutters." G. J. F. M. MATTIOLI.

EMBOSSING PHOTOGRAPHS.—No. 12,182. "An Improved Method of Backing Embossed Photographs, Prints, Cards, or other Embossed Articles." H. PIQUET.

LENSES.—No. 12,219. "Improvements in Lenses." P. RUDOLPH.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

June.	Name of Society.	Subject.
22	Bradford	*Choice of Apparatus, Selection of Subject, Use of Swing Back, &c., and Exposure.* Walter Booth.
22	North Middlesex	*Observations on Picture Making.* F. C. Tilney.
23	Ashton-under-Lyne	Exhibition of Views of Lichfield Cathedral.
23	Birmingham Photo. Society	*Architecture.* Charles Morgan.
23	Hackney	Discussion on Printing.
23	Royal Photographic Society	*A Practical Demonstration of Colour-screen Making and Testing.* F. E. Ives.
24	Leytonstone	Annual General Meeting.
24	Photographic Club	Toning Silver Prints.
25	London and Provincial	Annual Meeting.
27	Ashton-under-Lyne	Excursion: Middlewood, for Poynton Pool. Leader, Miss Marsland.
27	Borough Polytechnic	Excursion: Ealing and District.
27	Croydon Camera Club	Excursion: Epsom Downs Station, for Headley, &c. Leader, A. W. Hirst.
27	Croydon Microscopical	Excursion: Staines and Chertsey. Leader, Mr. Lincoln.
27	Leytonstone	Excursion: Billericay. Leader, Dr. W. P. Turner.

ROYAL PHOTOGRAPHIC SOCIETY.

JUNE 16,—Photo-mechanical Meeting,—Mr. T. Bolas, F.I.C., F.C.S., in the chair.

Mr. E. SANGER SHEPHERD read a paper on

COLLODIO-BROMIDE AND TRANSPARENCIES FOR PHOTOGRAVURE.

Transparencies for photogravure, he said, must possess the greatest range of gradation, and must not be too dense, and, when a negative would yield such a transparency in autotype tissue, that method was the most suitable. In the case of flat or over-intense negatives, however, or when it was necessary to alter the size, the best means of obtaining a transparency was by the use of collodion emulsion. He preferred an unwashed emulsion, with an excess of bromide, with which the coating could be effected in a fairly bright yellow light, the plate being afterwards washed in a safer light. To make ten ounces of emulsion he gave the following formula:—

Silver nitrate	250 grains.
Water	2½ drachms.

Dissolve by heat and add

Absolute alcohol	2½ ounces.

Then put into the stock bottle

Pyroxyline	50 grains,
Ether (·770)	5 ounces,

and add the silver solution as above.

The bromising solution was

Zinc bromide	200 grains.
Alcohol	2½ ounces.

After coating, allow the emulsion to become well set, and then plunge the plate into cold water and leave it until all greasiness has disappeared. Expose about the same as for wet collodion and develop with pyro and ammonia, as recommended by Mr. Brooks. For ordinary subjects, the best intensifier was pyro and silver, but, for line work, the lead intensifier was to be preferred. For line work in photogravure, there should be a very small amount of dust grain on the plate, and, where there were large black masses without detail, these should be allowed to take care of themselves in etching, being worked up afterwards, by which means the character of the fine lines was preserved. In very delicate work it was necessary to use a very fine grain and plenty of it, but, with coarse subjects, it was possible to employ two grains, first with bitumen and then with resin. He never used a substratum, and found that a narrow edging of indiarubber solution was quite sufficient to keep the film from slipping. In developing, the image should be kept as thin as possible, the requisite density being obtained by intensifying with pyro and silver for half-tone subjects, or with ferricyanide of lead for line work, treatment with sulphide of ammonium producing a deep black, which would not print through in several minutes' exposure to sunlight. The addition of a few minims of alcoholic solution of erythrosine to the emulsion rendered it possible to obtain excellent copies from originals on yellow paper, and, in cases where the originals were on paper tinted with aniline dyes, the colour could be removed by washing in water.

Mr. W. E. DEBENHAM asked whether it would not be possible to obtain a suitable carbon transparency from a weak negative by means of intensification with permanganate of potash?

Mr. SHEPHERD said a suitable result could be obtained in that manner, but the final effect of intensification with permanganate was so much greater than the visual effect that it was extremely difficult to tell when the requisite degree of intensity was reached.

Mr. DEBENHAM had found that, after treatment with the lead intensifier, a collodion film had a great tendency to crack in drying.

Mr. SHEPHERD said that, if the image was very thin and thoroughly fixed with hypo, he had never had any trouble.

Mr. F. E. IVES had made a very large number of collodio-bromide positives, and for line subjects had always intensified with copper bromide and silver, and, judging from the specimens shown by Mr. Shepherd, he thought this method was better than lead intensification.

Mr. DEBENHAM suggested that the water used for dissolving the silver in the emulsion would have a tendency to cause frilling, and

Mr. IVES said he had always been afraid to use any water, and it was quite possible to get the silver in without it.

The CHAIRMAN, alluding to the question of intensification, remarked that it was an interesting fact that a collodion-emulsion plate could be exposed and fixed without development, clear glass resulting, the image being entirely obtained by means of intensification with pyro and silver, although previous to intensification the image was quite invisible.

The ASSISTANT SECRETARY (Mr. Child Bayley) said he had used Schering's celloidin for washed emulsions, and found it so satisfactory that he would now use nothing else, the only objection being that it required at least twelve hours to dissolve. Mr. Shepherd had said that he kept his emulsion bottle in a tin box, to preserve it from the light; but he (Mr. Bayley) had never found that collodion emulsion in bulk was sensitive to light, and he showed a sample which had been kept on a shelf in an ordinary room for about two years without being affected. He asked Mr. Ives what form of bromide he used for an emulsion made without water?

Mr. IVES replied that with 95 per cent. alcohol, bromide of cadmium, sufficient time, and plenty of heat, he always succeeded in getting the requisite amount of silver dissolved; he made up the emulsion and let it stand for a few hours with excess of silver, and then added more bromide of cadmium and alcohol to neutralise the free silver.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JUNE 11. Mr. Thomas Bedding in the chair.

The HON. SECRETARY read a letter from Mr. Atkins, resigning his office of Hon. Recorder, in consequence of his removal from London. After expressing his appreciation of Mr. Atkins's labours, he proposed that he be elected an hon. member of the Association, as a token of its esteem, which was seconded by Mr. Henderson and carried unanimously, and suitably acknowledged by Mr. Atkins. The Hon. Secretary drew attention to a photogravure of Dr. Obermayer, by himself, in the *Journal* of the Vienna Camera Club, as an example of work by a spectacle lens.

Mr. J. E. HODD asked for opinions as to certain comet-like marks on a negative which he produced, and which was one of a dozen exhibiting similar defects. Amongst other suggestions were that the wrapping paper might have caused it, or packing face to face, while Mr. Hodd thought that during washing some particles driven from the tap at high pressure might have been forced into the film. Eventually Mr. Henderson subjected it to some experiments, but nothing definite was heard as to the cause.

PLATES FOR HAND-CAMERA WORK.

Mr. W. D. WELFORD opened a discussion on this topic by asking who uses quick plates for hand-camera work—in other words, Why use rapid plates when slow ones will do as well? It is constantly advocated that rapid plates be used, and he had been attacked for advising the use of slow plates. He had always held that rapid plates were more difficult to develop than slow plates, but this was often denied. In the next place, greater precautions must be taken as to the safety of the dark-room light. He claimed that there was less latitude in exposure, too, with fast plates, and one had to more nearly hit the mark compared with slow plates. Then, of course, there was the question of expense. He preferred slow to rapid plates, provided they were fast enough; and, further, he liked a slow plate with an energetic developer better than a rapid plate with a slower developer. Most hand cameras were generally worked too fast, and for which he could see no necessity. He thought exposures of from $\frac{1}{4}$ second and upwards were very useful; but, if great speed was required, some shutters are provided up to $\frac{1}{100}$ second. If he were going to work at such a speed, however, he would drop a hand camera altogether and use a stand camera. That the speed of the shutter is much too great could be verified by considering that most people with any experience could make an exposure up to two seconds with a hand camera, while an ordinary worker should certainly be able to give up to $\frac{1}{2}$ second. By slowing the shutter and adopting slower plates, he was sure much improved results would follow. He exhibited some of his own work, all, with one exception, being taken on ordinary plates, that is, of the first rapidity, and answering to Ilford ordinary. They were mostly taken with stop *f*·11, and some with *f*·16.

Mr. HENDERSON inquired what "Warnerke" speed this slow plate was to be?

Mr. WELFORD replied, Seventeen or eighteen.

Mr. HENDERSON called that a quick plate.

Mr. HODD endorsed most of Mr. Welford's remarks. All his work had been done on a slow medium plate. A fast plate was really very unsuitable for making enlarged negatives from, on account of the general coarseness of grain. He had some whole-plate enlarged negatives from these slow plates which required a sharp eye to discern that they were enlargements at all. Fast plates presented much difficulty in getting shadow detail, and there was less latitude. He did not understand why hand cameras were not suited for very rapid work.

The HON. SECRETARY felt bound to say he was inclined to take the other side, and support those misguided individuals in favour of rapid plates. The arguments used were very antiquated and showed a lack of appreciation of the efforts of plate-makers. That the rapid plate is more difficult to develop, that it gives less margin of error in exposure, that it induces coarseness of grain, and, consequently, is unsuitable for enlarging from, and that it is more susceptible to fog, may have been true years ago, but good rapid plates, with little grain, and which do not fog in ordinary working light, are now easily obtainable. This plate was of a speed of about 80 Hurter & Driffield, which was a rapid plate, and should not be classed with the plate advocated by Messrs. Welford and Hodd. He thought the tendency was towards under-exposure. As regards choice of stop, a great deal depended on the subject. For near figures, *f*·11 to *f*·16 were not very suitable, if you also want definition in the background. He thought the question of holding hand camera steady for an exposure of two seconds out of the question, and found it difficult enough to get sharpness with $\frac{1}{10}$ second.

Mr. HENDERSON agreed with the Secretary as to rapid plates being superior, and instanced one or two of Mr. Welford's examples that would have been better for a rapid plate.

Mr. RAPSON maintained that a better negative could be obtained from a forced, barely exposed, slow plate than from a rapid plate, over-exposed, with tentative development.

The HON. SECRETARY suggested that it would be well to compare fast and slow plates, to ascertain whether there was any truth in the contention that slow plates gave more gradation than fast plates.

The CHAIRMAN remarked that he had not been very successful in long exposures with hand cameras. About the grain of plates, even visually the grain varied considerably. As regards the main question, he would prefer a slow plate.

Mr. WELFORD had not touched the question of granularity, because very little argument could be founded upon it. He disagreed with the Secretary's opinion as to there being more under-exposures. Very little over-exposure of a rapid plate caused much flatness, and, moreover, it was exceedingly difficult to restrain a rapid plate when over-exposed. He advocated a stand for very fast work on account of the great vibration caused by rapid shutters, and by this means avoided it considerably. With reference to protracted exposures, there was nothing to prevent one from leaning against a tree or other support, and in this way two seconds could be easily given.

PHOTOGRAPHIC CLUB.

THE usual weekly meeting of the Photographic Club was held at Anderton's Hotel on Wednesday evening, June 10, Mr. Welford in the chair.

The HON. SECRETARY read a letter from Mr. Alexander Cowan, thanking him for the sympathetic letter which he had sent on behalf of the Club, and stating that he was getting along as well as it was possible to do under the circumstances. The Hon. Secretary handed round prospectuses and entry forms of the Bristol International Photographic Exhibition.

Mr. NESBIT showed negatives, made by his son and developed by himself, of the snake-keeper at the Zoological Gardens, with one of his pets encircled round his neck. Mr. Nesbit took the opportunity of thoroughly abusing those dry-plate makers who sent out plates which were badly cut. He said that, in a dozen $8\frac{1}{2} \times 6\frac{1}{2}$ plates recently purchased by him, six of them were too small, and he naturally felt aggrieved.

It was pointed out that, as these plates were whole-plates, it was probably the fault of the glass-manufacturer rather than the dry-plate manufacturer.

Mr. NESBIT said he did not care whose fault it was; when he bought plates, he wanted them to fit his slides.

Mr. Welford passed round some prints made on Eastman's matt Solio paper toned to a sepia colour. He used the Eastman platinum toning formula.

Mr. STRETTON said that, in connexion with the Club's proposed outing, Mr. Gotz and he had, amongst other places, been to Windsor, and, taking all things into consideration, their suggestion was that the Club should select that locality for its proposed day's outing. He suggested that the day might be changed to July 4, because in that case he could arrange to have his boat at Windsor, and the members would be able to make pictures from both sides of the river. He said that he was acquainted with the district, and that he would be pleased to place his knowledge and services at their disposal. The date was accordingly altered to July 4.

Hackney Photographic Society.—June 9, Mr. R. Beckett presiding.—A report of the excursion on the preceding Saturday to Leigh was given by Mr. Dean. A discussion was held on the lecture on *Lighting*, given the week before by Mr. W. E. Debenham. Mr. Hoddle, of Messrs. Thorn & Co., showed the

INCANTO ACETYLENE GAS GENERATOR.

It was claimed to be automatic, simple, portable, and safe. A demonstration of its action certainly seemed to agree with these claims, and the light produced was very good indeed, being very much brighter than the incandescent gas, and purer in colour. At the meeting it was subjected to a rather severe test, that of being placed in the club lantern. It illuminated the slides and screen very well, and is superior to any form of oil light or the incandescent gas.

North Middlesex Photographic Society.—June 8, Mr. J. Addison in the chair.—Mr. H. R. F. Wheeler was proposed as a member of the Society. Mr. MUMMERY reported on the last outing to Purfleet. Owing to the absence of Mr. S. H. Fry, who was to have demonstrated on rough bromide paper, and who had written to say he was quite unable to attend, owing to business engagements, the meeting devoted itself to asking questions and discussing various subjects. Mr. CHILD BAYLEY asked if any one had had any experience with isochromatic plates and a screen in a hand camera? Mr. H. STUART said that he had, and it was only a matter of exposure. He found he could give exposures up to half a second, with the camera held in the hand. Mr. SMITH asked for a platinum toning bath for paper prepared by Mr. Moss to formula. Various baths were recommended, among them the platinum bath issued with Solio paper. Mr. MATTOCKS said that, on opening one of Edwards's dark slides suddenly, he noticed a flash of light. This was said to be electricity, caused by the friction of the celluloid shutter against the velvet at the top, and is more likely to occur in dry weather. After a varied discussion on a developer for bromide paper and the permanence of prints toned in the combined bath, the meeting dispersed.

JUNE 15, Mr. H. Smith in the chair.—Mr. MARCHANT said that members would be glad to hear that the President (Mr. Mummery) had been elected to serve on the Hanging Committee of the Royal Photographic Society's Exhibition. Mr. W. J. SIMPSON then proceeded to give a demonstration on

SILVER PRINTING AND TONING,

meant especially for beginners. He said that home-sensitised albumen paper gave finer results than ready-sensitised, as the latter contained a considerable

amount of acid, in order to make it keep. He recommended the paper to be bought ready-salted and albumenised, as it saved a lot of trouble. The strength of the silver bath for floating the paper should be about forty-five grains of nitrate of silver to the ounce, and should be kept up to that strength by adding a solution of 120 grains to the ounce as required, testing by the argentometer. He also gave a volumetric test, using a solution of common salt of definite strength. The paper should be floated for three minutes, and then hung up to drain, and dried between blotting-paper soaked in carbonate of soda, which enabled the paper to be kept about a week. If this was not done, the paper would have to be used at once, as it would not keep. He recommended the acetate bath for toning—30 grains acetate of soda, 1 grain chloride of gold, 10 ounces water—this has to be made up twenty-four hours before using. The borax or phosphate bath could be used instead, and mixed just before using, 100 grains of borax or phosphate of soda being substituted for the acetate of soda. The prints should be fixed in a one to six solution of hypo, and well washed, but not kept soaking. He toned several prints in the acetate bath to a very rich dark brown, and also showed how to float the paper on the silver bath, several members taking away a sheet to print at home.

Liverpool Amateur Photographic Association.—On Saturday, the 6th instant, the members of this Society journeyed to Ellesmere, near Wrexham, travelling by the new railway from Seacombe. The party left the landing-stage at twelve o'clock, and reached Ellesmere about two. The day was a good one for photography, and several good pictures were obtained. An excellent tea was partaken of at the Red Lion Hotel, and Liverpool was reached, after a long journey, about a quarter to eleven. The party included some ladies, and numbered thirteen in all.

Correspondence.

MR. CHILD BAYLEY ON ART.

To the EDITORS.

GENTLEMEN,—Last week but one's edition of your JOURNAL contains some remarks by Mr. H. P. Robinson, the correctness of which I should like to contradict. He writes as follows: "Nothing has ever been more definitely and unanimously acknowledged, by friends and foes all over the world (always excepting Mr. Child Bayley), than the vast improvement in pictorial photography since the institution of the 'Linked Ring.'"

I am not connected "all over the world," but I am fairly well connected over our own little part of it, and I can assure Mr. H. P. Robinson that Mr. Child Bayley is not the "exception" in relation to his opinions as pronounced by Mr. H. P. Robinson. Many friends and acquaintances, as well as myself, are of the opinion that pictorial photography was exactly so far developed twenty or thirty years ago as it is to-day, and the "Linked Ring," is very much mistaken if he attributes in this direction any improvement to himself.—I am, yours, &c., F. B.

ASSISTANTS AND THEIR GRIEVANCES.

To the EDITORS.

GENTLEMEN,—From a most detailed description of "a leading lady photographer" in a letter from a Mr. Randall, in your issue of May 15, there can be no doubt as to the identity of that lady.

Now, from an intimate knowledge of the treatment accorded to the spotters engaged by her (knowledge not given to me by friends of any one), I deny, emphatically, that "a system of slavery" so grossly exaggerated and indignantly assailed by Mr. Randall exists, and more, that even slavery in its mildest form is carried on.

What does Mr. Randall know about wages? When, again, he expresses his opinion of the value of a worker, let him remember that wages are paid for competence, and that beginners are not paid the same as older hands. And for Mr. Randall to say he knows anything about the business, as a fact, that too I deny, though, if I remember rightly, he spent a day at this firm, yet he saw nothing of the spotters.

To accuse this lady of resorting to the degrading practices contained in the second paragraph of the letter under notice, to realise the weekly profits of 100*l.* attributed to her, and so generously published, is utterly false. I am not possessed of such eloquence as Mr. Randall, so must content myself with simply denying his charges, begging Mr. Randall to confine himself to facts, and not to write such things as his letter contains.—I am, yours, &c., NORI.

THE CARDIFF EXHIBITION.

To the EDITORS.

GENTLEMEN,—In reply to the letter in your last issue but one signed "Booth," I am very sorry indeed he should think fit to rush into print for the express purpose of holding up to ridicule a brother photographer of old standing, perhaps the oldest established in Cardiff. It is not everyone who can obtain the highest position, and, as long as a man is a good citizen and works fairly, he is entitled to respect. Cheap work is as great a necessity in every business as the expensive. As regards myself, I am much flattered by Mr. Booth claiming me as a friend, but this I put down as a joke, as he is the *funny man* of the Society; at the same time he has caught hold of the wrong end of the stick when enumerating all my business qualifications.

I was for many years a photographer in Cardiff before becoming a fine art dealer; my love for pictures gradually drifted me into the latter trade. As regards Mr. Booth being a professional, I can quite believe this; how long he has been a professional photographer I am unable to discover, but should say it is about five or six weeks.—I am, yours, &c., ALFRED FREKE.

Cardiff, June 9, 1896.

To the EDITORS.

GENTLEMEN.—I am glad to see that Mr. Faulkes, the Secretary of the Cardiff Photographic Society, has, after three weeks' serious consideration, given the Syndicate's version of amateur *versus* professional.

Before replying to his letter, allow me to give you a short outline of the history of the Cardiff Photographic Society. For years it was called the Cardiff *Amateur* Photographic Society. This title precluded the admittance of professionals. It was desired by several of its then members that professionals should be admitted, and the title was altered by omitting the word *amateur*, and, I believe, the professional brethren of the town were all invited, but only three joined, as far as I know—myself and two others.

This alteration of title did not make the other members professionals, as Mr. Faulkes wished me to believe, when they began to run this studio.

Mr. Faulkes states in his letter that the Photographic Society's name has been used *only* in connexion with the Exhibition of Photographs. I have a letter before me, headed "Cardiff Photographic Society," and signed "T. H. Faulkes, Hon. Secretary," which runs as follows:—

"It has been decided by the Executive Council of the Cardiff Exhibition that all season tickets shall bear a photograph of the holder thereof, and, as we have the concession for supplying these photographs, we shall be glad to learn at what price you are prepared to supply two midgets unmounted, and also what lump sum you are prepared to pay the Society for the sole right of taking these photographs. We need scarcely point out that this right should prove extremely valuable, even if the photographs were supplied at cost price, as it would bring about 5000 of the best people of the neighbourhood to your studio, most of whom would probably order copies of the photographs for their own use.

"We have also the sole right of erecting a photographic studio in the Exhibition grounds, and have power to allot space for this purpose to the extent of 1200 square feet, or 40×20, and shall be glad to receive your tender for this also. The photographer would erect the studio himself.

"Awaiting the favour of your kind reply, we remain, faithfully,

"T. H. FAULKES, *Hon. Secretary.*"

I certainly was asked to tender for this monopoly, but the ideas of the *Syndicate* were so large (400*l.*) that I did not tender, thinking then, as I do now, that it was a scheme to put money in the pockets of a few amateurs at the expense of the professional.

Mr. Faulkes states that, to his knowledge, I have bought the monopoly at two other exhibitions. This is not correct; but, even if it were, it would have been quite legitimate for me as a professional.

If the Cardiff Photographic Society is represented by this syndicate, they are like the weather toy I have seen—when the lady comes out it is fine weather, and when the soldier appears it is a sign of wet.

For one part of the year they pose as amateurs, and receive all the attentions usually bestowed upon such societies, and at another start in the profession.

During the four or five months previous to the Exhibition, the Committee never asked the professionals to join in their consultations, although members of the same Society; but, as soon as everything was cut and dried, they wanted to know what the professionals would give them. They really induced one photographer in the town to take the midget photographs for nothing, and he took 1400 or 1500, for which the syndicate received 1*s.* each, amounting to 70*l.* or over. Altogether, 5000 tickets have been issued, making a total of 250*l.*, which the profession was entitled to receive.

I should like Mr. Faulkes's definition of amateur as distinguished from professional, as he persists, in another portion of his letter, that I have put about "a report to suit my own ends"—that the studio is run by amateurs. Who is running it if not amateurs? At all events, I am content to take Mr. Faulkes's own statement of facts, and leave the public to judge. These are the facts. A few posing as amateurs open a studio at the Exhibition, and employ professional assistants to do part of the work. There would appear to be no comment necessary.—I am, yours, &c., ALFRED FREKE.

Cardiff, June 15, 1896.

To the EDITORS.

GENTLEMEN,—Mr. T. H. Faulkes, the Hon. Secretary of the Cardiff Photographic Society, in his lucid explanation as to how that Society became transformed into a syndicate, to practise photography as a business, says, "That the Committee did not intend to run the studio themselves your advertising columns will prove, but, not having received an offer for same, they were compelled to engage two professional operators with assistants," &c.

From the above one would imagine that the studio had already been

erected, and that it was necessary to engage the assistance, in order to recoup themselves, and prevent further loss. Such was not the case. It was the right to build that they offered, and that for a substantial consideration too. Professionals evidently could not see much chance of a return on the outlay, and did not tender. "Fools rush in where angels fear to tread," and the Cardiff Society, not to be denied, did the rushing.

Mr. Faulkes did not enter into particulars of another concession the Society had obtained, viz., the right to photograph each season ticket-holder, probably some 5000, for which they were to receive 1s. each.

With a commendable desire to advance the art-science, this unsophisticated Society proposed to professional photographers of the town that they should undertake this portion of the work at cost price of materials, or even without remuneration; this on the ground that it would be a splendid advertisement for the photographer. One gentleman, I believe, did take the work on the latter terms, but, whether he found it not quite so remunerative as he had anticipated, or whether he could not turn out the work fast enough, I trow not; at any rate, other photographers were asked to tender, with the result that some portion of the work was placed in their hands at sweating prices, and finally, when their studio was ready, even this wonderful concession was withdrawn, and the Society went "holus bolus" into the business themselves, with their sole rights to photograph all and everything, living or dead, within the Exhibition and its grounds.

Some one has said that "Barabbas was a publisher;" this must have been prior to the advent of the amateur photographer.—I am, yours, &c.,

15, *Newport-road, Cardiff, June* 15, 1896. T. BRIGGS.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & Co., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

Henry Goldsmith, Hay Cottage, Glen Aldyn, Ramsey, Isle of Man.—*Photograph of landscape. East Glen Aldyn, from the Craig.*

W. H. Jacob, Broadway Studio, Sandgate.—*A copy of an old photograph of the Viaduct at Folkestone, taken about thirty years ago.*

John Davis, 34, Cheltenham-street, Barrow-in-Furness.—*Three photographs of H.M.S. "Powerful," showing H.M.S. "Juno" and Barrow Shipyard; and two photographs of H.M.S. "Powerful."*

T. BRIGGS (Cardiff).—It was an oversight which, however, the nature of the letter renders quite immaterial.

ASPECT OF STUDIO.—LIGHT. A pocket compass will indicate whether the "supposed north light" is direct north or not.

F. H. BURTON.—Thanks for the cutting; it is very amusing. The moral is: Read THE BRITISH JOURNAL OF PHOTOGRAPHY.

SPOTS ON PAPER.—SPOTS. We should recommend you to send some examples of the defects complained of to the makers of the paper. They will, doubtless, be able to help you in the matter.

BLACKING SHEATHS.—A. J. FROAD writes: "Will you tell me the best way to blacken my tin sheaths, through your paper?"—They may be blackened with Bates' dead black varnish, or with shellac varnish, diluted with alcohol, to which some lamp-black is added.

COPYRIGHT.—M. MCNEIL. Certainly an amateur can make a portrait photograph copyright if he took it himself. If the vicar sat for the portrait under the conditions stated, you can certainly prevent any one from pirating the picture, even if it is to be sold in the same bazaar.

BITUMEN FOR PHOTOGRAVURE.—C. LEACH. This must be in fine powder and free from lumps. As you remark, it is very troublesome to grind it fine enough in a mortar and then sift it, but the bitumen may be had ready pulverised and sifted ready for use. Mawson & Swan supply it in that state, so we expect do Penrose & Co.

FADED BLINDS.—S. J. W. We cannot give you directions for dyeing faded green cotton blinds. That is a question for a dyer. However, we may say that you will, in all probability, find it better to replace the blinds by new ones. Faded blinds are generally very rotten, and not worth the cost of dyeing, and, moreover, washed or renovated blinds rarely travel well on their rollers.

JUDGING DISTANCE.—MARINE writes: "In calculating the exposure necessary for a moving object, you take the distance of object from camera in inches, divided by number of yards per hour at which object is travelling, multiplied by focus of lens in inches. How can I find distance of object from camera, as in marine photography it is not possible to measure distance?"—Messrs. Adams & Co. supply an instrument for the purpose; but, for marine photography, we should think any one could estimate near enough for all practical purposes; a few yards is not of very great importance.

THE GRIMSTON SHUTTER.—G. W. Knight says: "I have a Grimston patent shutter, which, I think, is termed the 'right about turn' movement, it being charged by an arm at the top. Will you kindly inform me where I can have same repaired and regulated? I have inquired at a photographic apparatus firm, and was told it was a French make; perhaps you can tell of an English firm who might understand same."—The Grimston shutter is made by Messrs. Wratten & Wainwright, 38, Great Queen-street, who will probably undertake its repair.

METHYLATED ALCOHOL.—S. KOCH. The only way to obtain methylated spirit free from the mineral spirit is to obtain a licence to purchase it in that state. The trouble of obtaining the licence is not great, and the occasional visit of the exciseman will not cause inconvenience. But this fact must be kept in mind, and that is important in your case, the licence will not enable you to purchase the spirit stronger than about sixty-four over proof, and you say you require it as absolute. Neither will the licence to buy the spirit, or one to use a still, permit of the spirit being redistilled to strengthen or purify it.

AMATEURS' RIGHTS.—C. W. writes thus: "Last week I went to photograph some ruins of an old priory. I was told by the caretaker that I could not photograph the ruins, as the owner of the property had given the sole right to do so to a local professional photographer, on condition that he gave a royalty on what was sold to the Cottage Hospital. Is not this interfering with amateurs' rights?"—Certainly not. Amateur photographers have no rights in other people's property. Owners of property—whether ruins or not—can, of course, do as they like with it, and admit who they like to it, and make any terms they choose.

FACTORY ACT.—FACTORY ACT. All the regulations of this Act may be obtained from the Office of the Factories Inspectors, London, S.W. The local inspector of your district will also give you every information. We do not see that "poor photography is being sat upon" because young people employed in photographic workshops cannot be kept after four o'clock on Saturdays any more than are dressmaking and kindred trades. The Factory Act is to prevent sweating. Surely photographic *employés*, like every one who has to earn a livelihood, require a little time for recreation, and that the Factory Act compels employers to give them.

INTENSIFICATION OF VARNISHED NEGATIVE.—J. Yes, the negative can be intensified notwithstanding that it is varnished, but the varnish will have to be removed first, and completely removed too. Immerse the negative in methylated spirit, and let it soak for half an hour or so, rubbing it occasionally with a pledget of cotton-wool. If the varnish dissolves off freely, well and good. If not, a little caustic potash or soda may be added to the spirit; this will aid the solution. When the varnish is dissolved off, rinse with two or three changes of spirit, and then wash out the spirit with water, and proceed to intensify in any way you have been accustomed to.

PHOTOGRAPHING FURNITURE.—R. W. says: "I shall have, in two or three weeks' time, to photograph a quantity of furniture, the negatives to be used for process blocks for a catalogue. The firm tell me I can photograph the articles either before they are polished or afterwards. As I have never done anything of the sort before, I thought I would do it afterwards, as I should get brighter pictures. The manager then remarked that, when they had had similar work done before, the photographer always had the things in the unpolished state. What would you advise?"—Photograph the goods in the unpolished state, by all means. It will save you a lot of trouble in the lighting, and the result will be very much better in the end.

PORTRAIT LENS.—S. E. BENN says: "I have recently been given a lens—a portrait lens—bearing the name of McLean, Melhuish, & Co., and one of the glasses is cracked; otherwise the lens seems good. I have looked in the *Post Office Directory*, and cannot find the name of the firm, neither can I in the advertisements in the ALMANAC or the JOURNAL, so as to get the glass replaced. Can you tell me the address of the firm?"—The firm used to be in the Haymarket, if we remember rightly; but it ceased to exist some decades ago. It was not a maker of lenses, but supplied those of French make, after examination. Any photographic graphic-lens maker would replace the broken glass, though it is a question if it would cost less than a new lens, unless it be of large size.

SALE OF BUSINESS.—R. S. says: "In the autumn of last year I bought this business of —— & Co. They assured me the returns were so much, and the profits a certain amount per cent. upon them. I have been in the business now for nine months, and I find the takings are not half what was stated. Can I compel them to take the business back and refund what I have paid? The people are substantial, and have other places."—Yes, you can, if you can produce evidence of fraud or misrepresentation in the receipts, not without. It must be borne in mind that in selling a business the vendor cannot guarantee that the purchaser will do the same amount of business he did, that must depend upon the customers, and how they appreciate the new comer, and many other circumstances.

PROCESS BLOCKS.—OBSERVER writes: "Is process block-making uncertain work, and do the present cutting prices cause the makers to turn out good, bad, and indifferent work, without rejection of the indifferent and bad? My object in asking this query is, that I see process blocks by the same firms, or, at least, bearing the same names at the corners, that are in some cases most excellent, and in others simply a disgrace to British process work. I can hardly imagine that these firms turn out different classes of work."—We do not surmise that they do; but what our correspondent complains about is, no doubt, due to the print, the paper, or the ink. Unless these are suitable, the best block may be spoilt in printing. Block-makers of repute turn out good blocks, but they are not responsible for their printing, and they are too frequently ruined in that operation.

Contents.

EX CATHEDRÂ.

The medals and diplomas awarded to British exhibitors at Chicago have at length been issued to H. B. M. Ambassador at Washington, and have been transmitted by him to the Foreign Office. Sir Henry Trueman Wood has been requested by the Secretary of State to undertake the duty of distributing them, and this will be done at once. All the exhibitors may expect to receive their medals within about a month from the present date.

* * *

We are requested to announce that a summer outing of the Photographic Club has been arranged for Saturday, July 4. Trains from Paddington for Taplow at 10.13 a.m. and 1.5 p.m. Mr. Stretton will have his boat near Maidenhead Bridge at the service of members wishing to visit the district above bridge, Cookham, Boulter's Lock, &c. Meet at 2 o'clock to 2.30 on Monkey Island for luncheon (2*s.*). Easy walk to Windsor during afternoon. Meet at Royal Oak, Windsor, for tea. Trains from Windsor at 7.5 and 8. The entire arrangements have been kindly undertaken by Mr. W. R. Stretton, of 4, Queen-street-place, E.C., and Mr. J. R. Gotz, 215, Shaftesbury-avenue, W.C., and members and their friends wishing to join the excursion, and desirous of obtaining railway tickets at a reduced rate (2*s.* 6*d.* return), should make their wishes known to one of these gentlemen not later than Monday next, June 29.

* * *

Professor Buka, of the Berlin Technical College, has, it is stated in a contemporary, succeeded in observing the internal organs, or some of them, by means of the X rays. He uses a screen consisting of a plain glass plate closely covered with paper, in which a U-shaped window is cut. Barium platino-cyanide is very evenly spread over this U-shaped space, and the whole is covered with a second layer of paper. The remainder of the apparatus is the usual Crookes' tube, a Ruhmkorff induction coil, &c. When the screen is placed before the luminous vacuum tube, the U-shaped space becomes fluorescent, and, if the outspread hand is brought between the screen and the vacuum tube, the bones, which, of course, are not penetrated by the X rays, appear on the screen as dark shadows with outlines. They may thus be directly observed, and the movements of the joints are equally visible on the screen. A still more striking phenomenon was the direct observation of the ribs, the respiratory action of which was quite perceptible; and, in addition to the osseous parts of the thorax, there came into view a dark mass on its left side, showing the distinct outlines of the heart. The liver also became visible, but the lungs, which are penetrated by X rays, were not seen.

* * *

The attention now being bestowed in many quarters on the probable utilisation of acetylene as an illuminant for photographic purposes invests with peculiar interest the report that a very serious accident has happened to Mr. Lennox, chief assistant to Professor Dewar, which was caused on Tuesday last week by the explosion of an apparatus containing acetylene that took place in the laboratory. It is stated that Mr. Lennox has thereby lost the sight of one eye. At present, we also learn, the sight of the other does not appear to have been impaired, and it is hoped this will be completely preserved. Particulars with regard to the cause of the explosion will, we are sure, be awaited with interest by photographers contemplating the employment of acetylene.

* * *

We occasionally receive from photographers in remote parts of the country requests for information as to the address of

any one undertaking the preparation of illuminated addresses for presentation purposes, and such an inquiry to hand this week gives us the opportunity of mentioning that Mr. W. Theodore Parkes, of 14, Nevill's-court, Fetter-lane, a clever artist and engraver, has recently submitted to us for inspection an illuminated address made by himself which was presented by the London staff of the *Irish Times* to the proprietor, Sir John Arnott, on his receiving the honour of a baronetcy. Alike in design, colouring, and execution, the address is a beautiful work of art.

* * *

A VALUED correspondent, Mr. George Baukart, sends us the description of a method he has adopted for the prevention of frilling in celluloid films, elicited by the complaint on the same subject made to us by Colonel Gubbins in the JOURNAL of June 12. Film-users generally, who find themselves working with films that are prone to frill, will probably welcome Mr. Bankart's remedy, which, he informs us, he adopted with collodion dry plates twenty-five years ago.

* * *

(1) PROCURE a small bottle of varnish made of amber dissolved in chloroform. (2) Get a small camel's-hair pencil, and tie it to a thin stick of cedar or wood like the handle of a painter's tool (artist's brush). The stick acts as a "guide" to the brush when applied to the edge of the plate or film. (3) Dip the tool into the chloroform varnish, and run it quickly round the edge of the film on the emulsion side. It will leave a fine film of varnish, which dries very quickly and is impervious to water. Care must be used not to use too much, or it will overlap the rebate edges of the plate (or film), and will prevent the action of the developer; but, if neatly done, it will be a perfect cure for frilling, and is easily and quickly applied. It will dry (enough to handle) in one minute. If it is desired to take it off the negatives *after* they are completed and washed, a little clean chloroform will do it. Guard against splashes or spurts of varnish on the film, as, if any spots settle on it, the development will be prevented. If the emulsion has been slightly separated from the support (in cutting up), the varnish will run in underneath it and cement it to the support.

* * *

WE have received the catalogue of the Photographic Exhibition now being held, under the auspices of the Glasgow Corporation, in the Camphill Gallery, Glasgow. It is prefaced by some brief but clearly written notes on photographic processes, given in historical order from the days of Niépce downwards, from the pen of Mr. James Paton, the Secretary of the Exhibition Committee, upon whom the work of organization has largely fallen. The Exhibition appears, from the list given in the catalogue, to be rich in features of historical interest, while examples of ancient and modern printing processes and apparatus are included, which will, no doubt, prove instructive and attractive to the visitors. The Exhibition will remain open, we believe, for another two months.

* * *

THE next meeting of the National Association of Professional Photographers will be held at Leeds during the Convention week, the annual meeting being fixed for Tuesday evening, July 14, at the Imperial Hotel, Briggate (the Association's headquarters). Mr. W. Barry, of Hull, is the President of the Association, which some time ago formally resolved to take part in the proceedings of the Convention. The Secretary of the N.A.P.P. (Mr. D. J. O'Neill), 47, Charlotte-road, Birmingham, will be glad to receive, as soon as possible, the names of members intending to be present.

* * *

THE Sixty-fourth Annual Exhibition of the Royal Cornwall Polytechnic Society will open at Falmouth on Tuesday, August 25, 1896. As usual, medals and prizes are offered for photographs by professionals and amateurs, and for photographic apparatus. Information respecting the photographic department may be obtained from Mr. W. Brooks, Laurel Villa, Wray Park, Reigate (member of the General Committee).

SLOW AND FAST PLATES FOR HAND-CAMERA WORK.

AT a recent meeting of the London and Provincial Photographic Association there was an interesting discussion as to whether slow plates or fast ones were the preferable for hand-camera work. The subject is a seasonable one to deal with just now, as the conditions under which hand cameras are employed at midsummer are widely different from what they are during the autumn or winter months. It is manifest that plates which can be successfully used now would be quite unsuited to a winter or an autumnal light. Of course, "fast plates" and "slow plates" are but comparative terms, and what some characterise as slow others consider as fast. This was the case at the meeting referred to. The majority of makers now supply plates of three degrees of sensitiveness, and opinions were varied as to which of these it is most desirable to use. The object of the worker, it is needless to say, is to obtain the best possible negative, and the question is, How is that best accomplished?

A slow plate is alleged to give a better, photographically, negative than a very rapid one. But, of course, a slow plate demands a longer exposure, and to give that entails greater risk of the camera not being held perfectly still during that period, as well as the chance of moving objects being palpably blurred in the picture; also a slow plate cannot be used with so small a stop in the lens as a quick one can without increased risk of movement, hence there may be a lack of sharpness in the different planes of the picture. With plates of great rapidity a quick exposure may be given, even with a small diaphragm in the lens; hence the chance of movement, either of the camera or the subject, is reduced to a minimum, while the greatest sharpness in different planes of the picture is ensured. But it is said that very rapid plates are difficult to manipulate, inconvenient to use, and that there is not the same latitude in the exposure that there is with the slow ones; also that the grain in them is so coarse that the negatives are unsuitable for enlarging from or for lantern purposes. The question is, In which direction does the balance of advantages lie?

It is quite true that at one time very rapid plates were characterised by great granularity of the image, so great, indeed, as to show palpably in enlargements, even of moderate size, and very pronounced on the lantern screen; but of late makers have given a deal of attention to this point, and very quick plates, if not the quickest, may now be obtained with a grain as fine as that which was only to be had on "ordinary plates," so that part of the question may be dismissed. With

reference to the subject of manipulation there is no question that plates of ultra rapidity are somewhat more inconvenient to use, and do require greater skill in working than slow ones. For this reason novices are more likely to obtain better negatives photographically on the latter than on the former. Then comes the question of movement during the exposure. With objects in motion, the exposure must be so brief that no visible movement is shown, yet sufficiently long for full detail to be secured in the shadows of the picture—a quality too frequently absent in hand-camera work. Then comes the immobility of the camera during exposure. A second is a very short time, yet there are few hand-camera workers who can hold the instrument absolutely still for that period, or for even a quarter of the time. There is no question that, the briefer the exposure can be made, the less chance there is of blurring from movement either of the camera or the objects photographed.

There is no doubt whatever that many work at quite an unnecessary speed, and employ plates of unnecessary rapidity, thereby increasing their difficulties and the uncertainty of their results. An exposure of the twentieth or the thirtieth of a second is quite sufficient for most hand-camera subjects—street scenes, and the like—with a lens of moderate aperture, and there is no difficulty in holding the camera quite still for that time. Any good lens of not less than five and a half inches focus—such as most hand cameras are furnished with—will cover the quarter-plate well with an aperture of *f*-11, and such a stop will suffice for rendering the different planes in most subjects quite sharp. Under these conditions plates of what are known as of medium rapidity—intermediate between "ordinary" and "extra rapid"—will, in an average light, suffice for all ordinary purposes. Why, then, it may well be asked, use extremely rapid exposures, when they are not required, which entail the employment of ultra-quick plates, with their accompanying inconveniences, and, in unskilled hands, uncertainty in the results? We are not referring to work in the winter months, when, of course, circumstances are different from now.

Plates of extreme sensitiveness are a power at command, and when the light is dull, and with some subjects, results may at times be secured with them which could not otherwise be obtained; therefore it would sometimes be an advantage to carry both kinds of plates, and expose either as occasion may require. This, unfortunately, the majority of magazine cameras will not permit of being done. It is here that dark slides and changing boxes have an advantage. If a magazine camera could be arranged to carry two different kinds of plates, so that either could be exposed at will, it would often prove an acquisition when the acme of perfection in results is aimed at.

Another New Test for Iodides.—This is founded on the fact that thallous iodide is quite insoluble in cold dilute alcohol, even in the presence of salts of ammonia and other compounds in which, when dissolved, thallous chloride is taken up. The iodide is precipitated out of a 30 per cent. alcohol solution by a 4 per cent. solution of thallium sulphate, and the thallous iodide thrown down after standing half a day washed with a mixture of 30 per cent. alcohol, containing 5 per cent. of ammonium sulphate, washed in a filter, dried at boiling point, and weighed. Any chlorine present is estimated by precipitation with nitrate of silver, after first boiling the filtrate to expel the alcohol, and adding about 3 per cent. nitric acid. Bromine is found in a similar manner, but the result is less exact, as thallous bromide is not entirely insoluble.

The Platino-cyanides in Röntgen-ray Work.—The opinion of observers upon the relative values of the various platino-cyanide salts is by no means unanimous. T. Argynopoulos has been experimenting with the various compounds with the object of ascertaining their respective powers, and finds the barium salt to be inferior to those of either the potassium and sodium or potassium and lithium salts. He found the luminosity with the former was visible at a short distance only, while with the latter salts the luminosity was visible at five feet distance.

An X Ray Meter.—This is the name given by Messrs. Reynolds & Bransom, of Leeds, to an ingenious and simple little instrument they have devised for readily ascertaining the strength of the rays from a focus tube. It consists simply of a series of layers, like terraces, of metallic aluminium, in the form of a quadrant. The meter is placed between a fluorescent screen and the focus tube, and can thus be used as a measure of one tube's capacity against another, or for ascertaining the relative strengths of the radiations from various parts of the tube. Of course, if a permanent register be required, a sensitive plate will be used in lieu of the phosphorescent tablet.

Uranium as a Radiation Source.—M. Henri Becquerel has shown that this metal gives off radiations of photographic potency after passing through such opaque bodies as cardboard, aluminium, copper, platinum. The effects are precisely similar to those before described, obtained with salts of the metal, but are about four times as powerful.

At a meeting of the Royal Society of Edinburgh last month Professor Chrystal suggested the use of metallic uranium for intensifying Röntgen rays.

The Action of Light on Ferric Chloride and Oxalic Acid.—M. Georges Lemoine has been investigating the proportions of this action, his arrangement for varying the intensity of the light falling on the small cell in which the liquid is contained consisting in the use of two large polarising prisms. The result of his experiments goes to show that the chemical action is directly proportioned to the visual intensity of the light, there being no appreciable "period of induction." The result was the same whether the total amount of light was permitted to act continuously or at intervals. He found, too, that on calm, cloudless days the visual intensity of the light remained virtually without alteration for comparatively long periods.

Combustion of Acetylene.—The following figures, extracted from the proceedings of the Paris Academy of Science, will be of interest in connexion with the burning of mixtures of air and acetylene, seeing that it has often been stated that the presence of air is advantageous to its due combustion. Air with 7·74 per cent. of the gas burns completely, the product being carbonic acid gas, and the flame pale yellow, with little illuminating power. Between that proportion and 17·37 per cent., hydrogen and carbonic oxide are found in the products of combustion; the flame is pale blue, with a feeble yellowish aureole. With more than the latter proportion the combustion is incomplete, some unburnt gas being found as well as hydrogen and carbonic oxide, and the flame is red and smoky. 2·8 and 65 per cent. are the extreme limits within which combustion takes place.

Experiments with "Dark Light."—M. Gustav le Bon continues his experiments on this subject, which appear still to attract but little attention in comparison with that given to the Röntgen rays. Seeing that the dark light appeared to possess many characteristics in common with electricity, he supposed it might be possible to condense it, like electricity, on the surface of metallic plates, and his experiments have borne out his suppositions. The following are his conclusions:—*Invisible Radiations of Fluorescent*

Bodies.—These pass through metal; they are reflected and refracted, and consequently show none of the characteristics of Röntgen rays. *Röntgen Rays.*—These do not pass through metal, and are neither reflected nor refracted. They pass through black paper. *Radiations from Metallic Surfaces illuminated by Visible Light.*—These pass through neither black paper nor the majority of organized bodies, but do pass through a great number of metals. They possess also the property of being condensed on the surface of metals. *Radiations proper to Organized Beings.*—Radiations are emitted in darkness by organisms, and can produce photographic effects which M. Le Bon has shown by operating on ferns, fishes, and various animals. They seem to be connected with the radiations of invisible phosphorescence, only they differ from them in being unable to pass through the metallic bodies, especially so with aluminium, with which the author experimented.

Home-made Chloride of Gold.—We have on more than one occasion, when writing on the subject of the saving and conversion of residues, advised our readers, or those of them who are unversed in chemical manipulation, to leave the conversion, at any rate, to those who are competent to undertake the task, for, even when successfully performed, it is questionable whether it results in any economy to do it at home; but, when the work is inefficiently carried out, the actual loss may be, as in a case that has just come under our notice, out of all proportion to any saving that could possibly accrue. There are very many of our readers, too, who not with a view of economy, but rather for the sake of the experiment, will persist in the attempt to convert their own residues, and to those also we give the same advice, "Leave the task in competent hands. it will pay you better." It is a very easy and simple matter to dissolve so much silver or gold in nitric acid or aqua regia, but it is altogether a different affair to produce a satisfactory product.

Such was the experience of a young amateur who has just appealed to us in his distress. Everything had gone wrong in his printing arrangements, and, no matter whose paper he used, not only could he get no decent tones, but all the detail was bleached out of the prints. The toning bath—the formula, at least—was the same he had formerly used with success, except, as it turned out, he was using his own chloride of gold. He did not think there was anything wrong with that; "nothing could be easier than to make chloride of gold, he could not see where any one could go wrong." Yet, unfortunately, he had gone very wrong. Simply he had dissolved his gold, using plenty of acid, which was perhaps what made the operation so easy, and, after evaporating to dryness, redissolved the result to make up a solution containing by calculation one grain of chloride of gold per ounce. As a matter of course, his solution was terribly acid, which he did not at all take into account, and, if he had done, the result would not have been greatly improved, and so all his troubles arose.

It cannot be too strongly borne in mind by those who will dissolve their own gold residues that it is of the utmost importance to get rid as completely as possible of all traces of acid. Formerly this did not matter so greatly, but with modern printing papers the retarding influence of soluble chlorides in the toning action is so great that the old practice of neutralising an acid solution of chloride of gold with chalk is of very little avail. The only possible way of working is to prepare the chloride in a state of neutrality, and it is just there where the difficulty comes in. Any "muff" can dissolve the gold if he has it.

JOTTINGS.

The illustrious Goethe's dying aspiration is said to have been "Light; more light!" In a different sense to that meant to be conveyed by the expiring author of *Wilhelm Meister*, his words have frequently been echoed by photographers pining at times for more daylight, for more "light" in the dark room, and for new and improved artificial illuminants. In the latter regard the newest claimant for notice—acetylene—is likely, as I have already pointed out, to engage and deserve much attention during the coming winter. By that time I hope the calcium carbide that is then available will be pleasanter to use than some I have recently had occasion to experiment with. I may have been unfortunate with these particular samples, but the odour they gave off strongly resembled the overwhelmingly complicated perfumes you sometimes encounter at gas works, or in the vicinity of a sewer—so much so, that my "search after knowledge" of acetylene, which I was recently conducting in my domestic abode, was the other night ruthlessly stopped by the peremptory refusal of its other inhabitants to put up with the "nasty, sickening smell." Do all samples of the carbide behave in this way? and, if so, how can the smell be thrown down?

There appears every probability of the Convention meeting of 1897 being held in East Anglia, Norwich marking itself out as a most suitable centre. Opportunities will surely be given for exploring some of the quiet and charming rivers and broads of the English Holland, as it is sometimes called, while, in addition to the places named, such towns as Bury and Ely are full of interest for the photographer and the archæologist, so that all the elements are to hand for assuring a good meeting. I wonder if it would be possible to secure the co-operation of that enthusiastic lover of East Anglia, Dr. P. H. Emerson, and persuade him to lead an excursion? Better still, why not Dr. Emerson as President?

A very great number of plates are exposed during these Convention meetings and on the whole, taking circumstances and conditions into consideration, the number and the average quality of the results obtained are fair. But far less "serious" photography seems to be attempted than might be the case. Now, as an exhibition of photographs forms an attraction at each Convention, would it not act as an incentive to Convention photography to institute a section for photographs taken at places visited by the members, and offer Convention "plaques" for the best work? I suggest plaques because medals and certificates are done to death elsewhere, and an artistically designed plaque might have an ornamental as well as a commemorative value.

Mr. Child Bayley has heroically resisted the temptation to reply to Mr. H. P. Robinson and the other critics who took him to task over certain portions of his paper on photographic societies and photographic art. I am the more surprised at this "mute but glorious" attitude, as at least two of those who ranged themselves against him afforded him the opportunity for a highly effective rejoinder. However, I merely interpose for the purpose of protesting, in the mildest manner, against the admirable advertisement which Mr. Bayley, a sturdy anti-Salonite, has given the photographic Salon. Mr. Maskell should send a cheque for at least 5*l.* 5*s.*, half for Mr. Bayley, and half for the editor of the Journal for having published the advertisement in its columns. The references to the Salon having nobbled the lay press, sold photographs at good prices, and attracted artists and photographers to its exhibitions, are calculated rather to entrap than repel the average would-be exhibitor, so that I should not be surprised if the Committee of Selection did not this year have a larger and more varied number of pictures to choose from than hitherto. I am disappointed that Mr. Bayley missed one obvious point, which is, that, while the Salon may be allowed to claim having done something for "Art," nobody will dream of accusing it of having done anything for photography. While the Royal Photographic Society continues to advance the interests of photography, in all its varied aspects, as it has done during the past two or three years, it has nothing to fear from the sporadic competition of the Salon.

I hear that Mr. J. Bulbeck, a clever worker personally known to many of my readers, is about to commence practice as a photographer, mapping out for himself a field embracing the best and highest class of technical work. He will have associated with him my young friend, Mr. John H. Avery, than whom as an architectural

photographer I know nobody better. I wish the new firm every success.

I was much interested in the description given at page 347 of Mr. W. I. Chadwick's plan of photographing animals to scale by using a lens of known focus, fixed at a known height, in conjunction with a screened and measured framework, which, by means of a system of double printing or otherwise, would enable the actual and proportionate size of the animal to be read off in the photograph. For breeding and stud purposes the plan should be decidedly useful, and it is probably worth the attention of the Jockey Club and other societies interested in thoroughbreds and live stock. The plan, which is reminiscent of the Bertillon anthropometrical system, might also be found serviceable with human beings, as cases (outside the criminal jurisdiction), doubtless, occasionally arise where it is desirable to have a reliable photographic attestation of a man's height and "points," say, for example, in corresponding with a lady through the post with a view to matrimony; in applying for a situation as footman, or as janitor at a music hall!

From the discussion on the subject of the photographic installation at the Cardiff Exhibition, that has been running in these pages for some weeks past, it seems that the old controversy, amateur *v.* professional, has recently broken out at Cardiff in a very acute form. The Cardiff Society, it appears, is administering the photographic monopoly at the Fine Art and Industrial Exhibition, and seems in a fair way to make a profit out of it. The local professionals rise in arms against this "amateur" usurpation, which provokes the retort that the concession was open to professional tender: and this, in its turn, brings forth the rejoinder that there was no chance of professionals making a profit out of the "rights" offered to them.

The Cardiff Society is evidently composed of smart business men. They have set up as professional photographers. They have a studio in the Exhibition grounds; they have the concession for photographing the season ticket-holders; they try to sub-let these concessions; they fail, and so they work them themselves, pocketing the profits, risking the losses, as other business men (and photographers) do. I entirely sympathise with Messrs. Freke, Horton, and Briggs in their protest against a society, ostensibly formed, I suppose, for the study and advancement of photography, entering into competition with professional photographers and continuing to call itself a "Society." It is in reality a photographic company if ever there was one.

Apparently the professionals had no chance of *directly* tendering for the concessions, in which case it appears to me that they have simply been elbowed out of a field which was rightly and legitimately theirs. There are many amateur societies that confer great advantages on photographic progress by occasionally engaging in exhibition management, but this is the first instance I have met with in which that course has operated to produce the effect of taking the bread out of professional mouths, and I hope it will be the last. COSMOS.

HALF-TONE SCREENS BY PHOTOGRAPHY.

III.

SINCE I wrote on this subject a few weeks back I have had several letters asking for information on points which it appears I have left somewhat obscure, and as there may be others to whom the following remarks may be useful, I propose to add to what I have already said.

First of all, I must thank an old friend for his joking letter charging me with having "gone back to the bath at last," but I would point out that I have not. In recommending bath plates in preference to emulsion, I thought I made it sufficiently clear that that recommendation was made for the benefit of those who are not well-versed in the preparation of collodion emulsion. Where suitable materials are available and an intimate knowledge of collodion emulsion work, just as good results can be obtained with the latter form of films and with less trouble to the regular emulsion worker; but I expect the very reverse will be the case with the habitual wet-collodion man, for whom the advice was chiefly meant. In fact, of two men equally unacquainted with collodion emulsion, the one who happened to be well up in wet-plate work would be at a decided disadvantage as compared with one who knew nothing at all about it, since he would have a good many things to unlearn before he would feel comfortable with emulsion, whereas the simple washing and drying of a wet plate would present absolutely no difficulties.

Then, again, with unsuitable pyroxyline and solvents of doubtful strength, the preparation of an emulsion that will give an absolutely structureless film, such as is required for the present purpose, is a perfect impossibility, and to attempt to carry out the work under such conditions would be simply to court failure. After all, though I commenced by "denying the soft impeachment" of going back on emulsion, I am not very sure that for this particular class of work—the reproduction of screens—if I had a lot of work to do, I should not prefer the bath on the score of evenness of film, though, on the other hand, perhaps the balance of advantages would perhaps turn in favour of emulsion.

The difference between the two processes is just this, that, whereas a perfectly fluid collodion may be very highly salted, an emulsion containing the same quantity of bromine, in the form of bromide of silver, would be too thick to flow with anything like the smoothness necessary. The collodion, moreover, can be filtered under pressure through the very finest of filtering media without injury, but such treatment applied to an emulsion would rob it of the bulk of its sensitive material.

Two or three correspondents join issue with me in the matter of simply bromised or bromo-iodised collodion, on which particular question I am not going to take very strong ground either way. As I said in my previous article, the presence of a little iodide is advantageous, on the ground that it renders the film less liable to halation or internal spreading, which is a matter of no little importance. But I cannot go to the same length as my correspondents in believing that an ordinary bromo-iodised collodion is more sensitive, and in every way superior, to simply bromised when used dry. On the contrary, I emphatically deny this, although I am free to admit that possibly an old "wet" hand may prefer—at first—the bromo-iodised plate. After a little experience, however, with a strongly bromised collodion, I think he will alter his opinion, and find that he will not only get greater sensitiveness, but also far greater density of image and contrast. However, this is a point on which convenience or individual fancy will be studied more than quality of result, as either form of collodion will work satisfactorily.

There is this to be said equally in favour of the bath—inasmuch as it gives less "structure"—and of simply bromised collodion, that it is only where these conditions are observed that the "reversal" process can be successfully adopted. It is quite possible for ordinary negative work to use an emulsion that shows a very decided amount of mottling and irregularity of film before fixing, but which disappears entirely in the hypo. This is owing to the fact that the development proceeds downwards from the surface of the film, and, unless it be carried right through to the glass, the image is tolerably uniform in character, and the unevenness lies in the unreduced bromide, which is removed in fixing; but, when we turn to the 'reversal' process, it matters not whether development is carried right through the film, as it ought to be, or whether it reaches only partly through, the final result is the same; the bulk of the original mottling remains in the bromide unreduced by the developer, and when, after the removal of the negative image, this is in turn reduced, it stands to reason that the unevenness remains in all its original force, if not with added intensity.

So far as the presence of a small proportion of iodide is concerned, I do not think that it interferes in the slightest degree with the reversal of the image, but the conditions are altogether altered when, as in the case of an ordinary wet-plate collodion, the film is chiefly composed of iodide of silver. It is usually supposed that, when but a slight trace of iodide of silver is present with the bromide, the two undergo simultaneous reduction by the alkaline developer, but this can scarcely be the fact when the iodide preponderates. Were it so, the presence of the iodide would be in no way detrimental, since, if it suffered reduction, it would also be amenable to the action of the nitric acid or other solvent subsequently applied. Upon such a bromo-iodised film—that is, one containing a very large proportion of iodide—it is quite possible to develop a strong, vigorous image

with alkaline pyro; but, if this be treated with nitric acid, instead of dissolving completely, as in the case of a plain bromide film, the iodide of silver remains behind as a veil over what should be the transparent portions of the negative or positive as the case may be. Theoretically, the reapplication of alkaline pyro should reduce only the bromide of silver left behind, and leave the iodide to be removed by a second fixing; but, practically, it will be found that the alkaline developer has sufficient action on the iodide of silver to produce a badly veiled reversal; for which reason, if for no other, I think a very small proportion of iodide is admissible.

No doubt, those who uphold the use of the ordinary wet-plate collodion have not had the reversal process in view, as it is not all who would choose to adopt that plan. But others amongst my correspondents complain that they cannot get clear reversals either with nitric acid or ammonia (iron-alum). These are possibly using bromo-iodised collodion, which would, as I have shown, produce the result, or, more likely, have not carried the first development sufficiently far; or, again, have been using too thick a film of bromide, which the developer is incapable of penetrating completely. Where the reversal method is to be adopted, the film of silver bromide should not be too thick for the developer to penetrate in a reasonable time; indeed, I think the best results are attained, and with much greater ease and certainty, with a film decidedly thinner than would be used for an ordinary negative. If this point is attended to, and the development carried some degrees further than it would be if a direct negative were being taken, the image will go right through to the glass, and, on the application of the nitric acid, perfectly clear glass lines will be obtained. The only effect of over-development is to reduce the general density of the final image, but this is not of much moment if the image has been developed through to the glass, as bromide of copper will give any amount of density without the opportunity of filling up the transparent lines.

There is one other point in connexion with the chemical side of the manipulations that I may touch upon, and this holds good, I think, in every branch of process work where alkaline development is used. Many operators err in trying to get full density in development, which, in the majority of cases, only leads to filling up the clear lines or dots. If a proper exposure be given, and a quick development, with a strong, well-restrained solution, a result will ensue that, for ordinary portrait or landscape work, would be described as "hard"—that is to say, the shadows will be clear glass. If the negative be now fixed, and intensified after fixing, there is almost no risk of filling up the shadows; whereas, if the intensification be carried out before fixing, development is going on, more or less, at the same time. The old rule with collodion dry plates used to be—for *contrast*, intensify after fixing; for *detail*, before.

Turning to the other side of the question, several correspondents complain that they cannot get square dots, however close the screen may be to the plate, and even when using a square stop. Well, I do not know that this matters very much; for my own part, I think that circular dots, which when reversed form a cross line screen with circular apertures, should theoretically behave better than square ones, just as a circular lens is used in preference to a square one. If modern screen theories be correct, these apertures act as minute lenses, and, that being the case, the circular aperture is the better. I do not say it is impossible to get square dots, but it is very difficult except when they just close up and form the chessboard patterns; and this holds equally good whether the screen is being copied in contact with the plate or in the ordinary way for enlargement or reduction. The circular shape seems to depend upon the spreading action of development rather than upon any other influence, for, if a very short exposure be given, the dots *are* square, but the deposit is not thick enough to be of any practical use. There can be little doubt that, were it a matter of importance, the exposure and other conditions could be so adjusted as to form square dots, but it seems to me the circular ones do very well and are less trouble. W. B. Bolton.

FOREIGN NEWS AND NOTES.

Glazing Shadows.—Count Vittorio Turati, of Milan, recommends, in the *Photographisches Archiv*, glazing as an important means of improving the shadows and deep tones in process prints, platinotypes, bromide prints, &c. The process is a simple one, and gives excellent results in the hands of the man of taste, but even the ordinary worker, who must study cheapness and rapidity, will find it worth attention. The print is coated with bichromated gum, or other medium, again exposed in the printing frame under the negative, and afterwards washed in tepid water. The shadows retain the gum rendered insoluble by exposure to light, and their depth and transparency are considerably enhanced. Accurate register is not of much importance for the second printing. As a further means of increasing the effect, a slight addition of colouring matter, of either cold or warm tone, according to subject, may be made to the gum solution. Similar processes are used in chromotype, chromo-lithography, &c., where the shadows are treated with varnish. Recent American process prints also exhibit a glazing of this sort, and thereby gain considerably in character and attractiveness. Count Turati thinks both glazed and matt surfaces are open to objection individually, but combined they should carry all before them.

Röntgen Photography.—Eder and Valenta give an account in the *Photographische Correspondenz* of experiments they have made to reduce the exposure. The definition in the photograph increases with distance between tube and subject; but, as the intensity diminishes as the square of the distance, a point is soon reached beyond which it is useless to go for practical purposes. Orthochromatic plates were not found of any use to shorten the exposure. Fluorescent substances were tried in conjunction with ordinary plates. A screen of barium platino-cyanide gave negative results, and a uranium glass plate was also of no use. A plate was dipped in a solution of sulphate of quinine, but did not show increased sensitiveness, perhaps due to the presence of moisture, which lowers the efficiency of the rays. Better results were obtained by warming the plates to 50° C. on a water bath. Winkelmann's and Strombel's experiments with powdered fluorspar were also tried, and gave good results. Films gave still better pictures, and it was found that the exposure might be reduced to one-half, or one-third, by placing the sensitive side of the film in contact with the powdered fluorspar, but a certain granularity was noticeable in the photograph, due to the powder, which could not be entirely obviated by repeated grinding of the fluorspar in an agate mortar.

The Goerz Lens.—The *Photographisches Wochenblatt* gives an account of the Goerz lens factory, which now employs 250 workmen on the premises and forty opticians outside. On December 2, 1894, was celebrated the completion of the 20,000th lens, and the number has since risen to 29,000.

Pyrocatechin.—Liesegang draws attention in the *Photographisches Archiv* to this substance as a developer for chloride prints. Owing to the lower price at which it is now procurable, it may attain some importance as a developer for dry plates. Prepare the following solutions:—

A.

Water	250 grammes.
Acetate of soda	50 „

B.

Alcohol	200 grammes.
Pyrocatechin	10 „

For use, equal quantities of both solutions are taken and diluted with water, according to exposure or strength of contrast required. For soft prints ten parts each of A and B, with fifty parts of water, are recommended, but for great contrast increase A and B to twenty-five parts each. With the same developer less exposure will give weaker prints. Develop rather stronger than required for the final result, and tone in the usual combined bath. This will give prints of the ordinary photographic brown tone. Fixing without toning gives unpleasant tones and reduces the print too much.

Improving Process Negatives.—Dr. Eder, in the *Photographische Correspondenz*, gives the following chemical method for

modification of the size of the dots, which has been used with great success in the Vienna Technical School. For such a purpose the image of the screen may be more pronounced than usual in the negative. Smaller stops may be used, and pre-exposure can be utilised with much effect by means of a sheet of white paper, say for twenty minutes, at *f*-50 to *f*-60 with a square stop. The exposure is then made for the original, with a round stop, at *f*-15 to *f*-16, and should be in proportion to the pre-exposure, which in this case would be six to ten minutes. Develop with a four per cent. iron and sulphate of copper developer. Before fixing, the negative is intensified with hydroquinone and silver. Fix with cyanide of potassium, wash, and whilst still wet intensify by dipping in a solution of—

Sulphate of copper	120 parts,
Bromide of potassium	4 ,,
Water	1000 ,,

followed by quick, plentiful washing in water, and a bath of 1 part of nitrate of silver to 10 or 20 parts of water and a few drops of nitric acid. The negative is now reduced in cyanide of potassium solution, to which has been added a solution of iodine and iodide of potassium. This is carried so far that the dots in the shadows are fine and sharp, but still black on a transparent ground. After another washing, intensification with silver and copper, as before, is repeated, and the negative is again thoroughly washed, and then intensified with lead. This bath consists of—

Ferridcyanide of potash	6 parts,
Nitrate of lead	4 ,,
Water	100 ,,

Filter, dip the negative in the same, whilst still wet, till a yellowish white colour is attained. Wash thoroughly in running water, until the negative is whitish, then flow over it a solution of one part of acetic acid to one part of water, wash thoroughly and blacken with ammonium sulphide. The reintensification with copper may be omitted if the negative is clear and plucky after development. Dr. Eder recommends this method of correcting process negatives as practical and safe.

Orthochromatic Photography.—It is instructive, and sometimes amusing, to see ourselves as others see us. In an article upon dry plates for different photographic purposes, R. Jahr, of Heidelberg, says in the *Photographische Correspondenz:* "In England, where the use of orthochromatic plates has long been neglected, eager attention has been given to them of late, and of course with good results. But this could not happen without contradiction from persons who either cannot, or will not, go forward. We mention, as a curiosity, that, according to the experience of a certain Mr. White, colour-sensitive plates only show orthochromatic properties when they are used with a deep yellow screen and exposed a few thousand times longer than is necessary with an ordinary plate without yellow screen. Photographs of moving objects—not to mention sitters in a studio—are therefore impossible with these plates, and the whole process is only of importance for the reproduction of a few oil paintings. Contradiction is unnecessary for us in Germany. The writer can, however, mention that he has repeatedly taken instantaneous pictures of street scenes, in which tram cars going at full speed are quite sharp, and this on orthochromatic plates, without a yellow screen." The writer's appreciation of the use of orthochromatic plates in this country seems to be confined to the remarks of Mr. G. R. White at the Croydon Camera Club in January of this year (THE BRITISH JOURNAL OF PHOTOGRAPHY, p. 45). Perhaps German makers of orthochromatic plates will be sending over large consignments, now it is announced that instantaneous pictures may be taken on them without a yellow screen!

The "Wiener Photographische Blätter."—We can recommend the June number of this paper to our readers as an excellent one. It is published by the Vienna Camera Club, and contains two excellent photogravures besides a number of smaller illustrations. The frontispiece, a photogravure portrait of Dr. R. Obermeyer, by himself, deserves special attention for pose and artistic treatment. It was taken with a spectacle lens. We gather from this paper that an organized movement is on foot for photographing, with a view to publication, characteristic farm houses and farm buildings in Germany, Austria-Hungary, Switzerland, and frontier countries. Each country will have a separate part, which may be bought separately. As the associations of engineers and architects have taken the matter in hand, the work will, no doubt, be of great value as a record of country habitations.

PHOTOGRAPHIC WORKERS AT WORK.

VII.—How a "Meisenbach" Block is Made.

Just as America was named, not after its discoverer Columbus, but after Amerigo Vespucci, whose connexion with it was much slighter, so has custom conferred upon the half-tone block, made by means of a lined screen, the name of Meisenbach. M. G. Meisenbach, however, although not the inventor of such blocks, was the first to make the process a really commercial one, so that use and wont, in this case, has been nearer the mark than it frequently is. "Meisenbach blocks" are now frequently spoken of when half-tone blocks by other makers than the Meisenbach Co. are referred to, but that Company, whose works cover a considerable area at West Norwood, may fairly claim to be the pioneers in what has now become so large an industry, of which industry they enjoy a very large share.

The Meisenbach Company commenced business in Farringdon-street twelve years ago, but it was not long before they found that the vibration of that busy thoroughfare interfered seriously with the making of the screen negative, and that they would have to select a spot where this evil did not exist; so a site at West Norwood was chosen for the factory, which was then specially built for the work. Nowadays, of course, since the use of the copying cameras hung on a swinging framework has been introduced, vibration is not such a bugbear as it was in the early days of process, such as 1884, and many firms are able to carry on their work successfully in the heart of a big city; still the tendency is for such industries to go further away from the crowded streets and high rents of the metropolis, and, no doubt, the move which was caused by vibration has not been without other advantages besides.

Probably most of the readers of the JOURNAL are acquainted with the various stages by which a half-tone relief block is prepared; still, as a preliminary to our account of the works where so many are made, we will run over the operations in brief. The photograph, drawing, or other subject to be reproduced, is photographed, a wet-plate negative being made in which the tints of the original are broken up into a series of dots by means of a glass screen ruled with black cross lines placed immediately in front of the sensitive plate during exposure in the camera. From this negative a print is made either by the bitumen or by a bichromated gelatine process upon a zinc or copper plate, which plate is then etched by immersion in an etching solution such as perchloride of iron. The etching liquid eating away the unprotected parts, leaves those which have been protected standing up above the rest, as required by the printing press, and it only remains to mount the block "type high" on a wooden slab.

To come to the works themselves, we were first shown a separate building in which were the gas engines and dynamos for the electric light. It contained three engines, two of fourteen and one of twenty-four nominal horse power, of which two were in use on the occasion of our visit, and the other in reserve. Each gas engine is connected by a belt with a Siemens dynamo. From these dynamos is taken the current, which lights not only the arc lamps in the studios, but two large arcs for printing purposes, as well as a number of incandescent lights employed throughout the buildings for ordinary lighting purposes. After a glance round the neat and orderly engine-room, we returned to the main building, only noting on the way that there are three large stoves for the hot-water pipes, which are laid throughout the whole of the building for heating purposes.

The first of the operations alluded to above, that is to say, the preparation of the half-tone negative, is carried on in three studios, which contain in all thirteen cameras, each provided with its easel and a pair of arc lamps for illuminating the copy. While on the subject of the studios we may mention an incident told us by Mr. Dilworth, the manager, indicating how experience in a new industry has to be bought. "Here," says he, "is our first studio, which we built with a north light, thinking it would be best for copying purposes. We found it too weak, so that, when building the second studio, we gave it a south aspect, only to find that the strong sunlight cast the shadows of the window frames on the easels. Finally, in putting up the third studio, we disregarded daylight illumination altogether, and relied on arc lamps entirely." We found accordingly in all three studios the daylight practically ex-

cluded, although through the open door of one we caught a pleasant fresh glimpse of green leaves and grass.

The studios are lofty buildings with white walls, and are of a long rectangular shape. Down one side are the cameras, down the other a row of dark rooms for the operators, together with a little room for glass-cleaning. Each studio has an attendant whose duty it is to keep it clean and in order, and to provide the operators with all the clean glass they need. Patent plate is employed for the negatives, the image being cleaned off when once the block is made, and the glass used afresh.

From the studios we were taken into one of four rooms where the printing on metal is carried out. The negatives when made are delivered into the hands of the printers, together with a piece of metal the proper size. Both the albumen, the bitumen, and the enamelline processes are carried on here, the last-named being usually adopted for copper only. Mr. Dilworth told us that the larger proportion of the work done for newspaper and other publications printed on inferior paper was engraved on zinc, which was found best suited for that purpose; and copper for finer work, where high-grade paper and ink are used. For this purpose, enamelline is not much used, as the heating which the plate has to undergo in the process is likely to be detrimental to a metal with so low a melting point. For copper, the fish-glue or enamelline process is not attended with the disadvantage alluded to, and is employed with success.

Printing on to the metal plate is performed either by daylight or by means of an arc lamp of a very powerful nature (of which there are two in operation here), under which prints are obtained in from three to fifteen minutes according to the negative employed. There are four sets of printers in this department, whose employment we have described, and who hand the printed plates out to the etchers, who then take them in hand. Previous to this, however, each plate has its final dimensions indicated upon it by means of four lines, which are cut round the picture on the zinc or copper. The rough etching, or etching proper, as it may be termed, is carried out in a series of stoneware sinks which extend all down one long room. From these baths the etched plates are taken to a press and proved, the print so obtained being compared with the original. Plate and proof are then passed on, when necessary, to the fine etcher's room, where, by rolling up and rebiting, vigour is given and contrasts brought out, equal to the original copy. Here also it goes into the hands of the engravers, who give what final artistic touches may be necessary, after which the plate is cut to size and a final proof taken before it is mounted and made ready for delivery.

Having in this way passed through the works and followed the process stage by stage from the making of the negative to the mounting of the block, we found ourselves once more in Mr. Dilworth's office, and are shown a print from what is probably one of the longest half-tone blocks in existence, its dimension being a little over thirty-nine inches wide; the subject is a bird's-eye view of Oxford, and the appearance of the block all that can be desired. Before leaving we put our courteous guide through a little cross-examination for the benefit of our readers, and elicited from him the fact that there were now about 100 men in employment at the works, ten or eleven cameras being now in constant use. At the rate of ten negatives per day to each camera—no very extravagant estimate, and, when it is borne in mind that four, six, or even more, subjects are often copied on one plate—it will be seen that the works are capable, without any further increase of any kind, of an output of about 300 blocks per day, or 1800 to 2000 per week; or, for those who do not care for mental arithmetic, about 90,000 per annum, allowing for a fortnight's holiday in the year all round. When it is remembered that this is one firm only, the size of the half-tone industry is seen to be extraordinary for one of such rapid growth, and we find ourselves wondering of these blocks as some philosopher has of the pins—where they all go to?

The screens in regular use at West Norwood are of 75, 85, 110, 125, 133, 150, and 175 lines to the inch respectively, although others are used occasionally. Of these the 75 lines is that employed for newspaper and similar work, and is known as "open grain," 125 lines being styled "fine grain" and being that in the largest use. Some of the screens in use have been made on the premises, being photographic copies of the ruled screens, and these are found to be in every way satisfactory; in fact, it is no uncommon thing, where a number of blocks have to be made to some special out-of-the-way size of grain, to make a screen for them in this way.

Before leaving we asked Mr. Dilworth how long it takes to make a block throughout. "In the ordinary course," he replied "we have the finished block ready in two or three days. We often, however, have to get blocks turned out the same day as they come in, and, if required, a block could be pushed through in two or three hours, but high speed is not advisable where the best result is desired."

A FEW PERTINENT QUESTIONS.

[The Professional Photographer.]

A few well-known Michigan photographers who were exchanging experiences lately were asked to state six questions that they would like to have answered in the columns of the *Professional Photographer*. The questions below were given by them in response as being of especial interest at the present time, and, as it was intended at that time to devote this number to Michigan photographers as a Michigan number, a few good men of that State were asked to answer these questions. Some have responded, and their answers follow the list of questions.

The Questions.

1. What do you consider the most effective colour for mounts used for matt-surface papers—(*a*) for dark tones, (*b*) for sepia tones? Do you favour large or small mounts?—by small mounts are meant the usual cabinet size for cabinet prints, &c.

2. What do you consider the best background for show-case displays? What class of work does it pay you best to exhibit?

3. Does advertising pay, and what do you think the best method of advertising for the photographer?

4. What accessories do you use when photographing babies? How do you keep them "in pose," and what means, if any, do you employ to attract or give expression?

5. Do you favour Sunday work? Does it pay? Would you support a Sunday-closing Act if made general?

6. Of what actual value to you are the photographic journals?

(1) Answers to the Questions, by Chas. E. Heath, Grand Rapids, Michigan.

After a careful consideration, and experimenting with different colours for mounting the matt-surface picture, I have come to the conclusion that, while there are a variety of colours which are effective and harmonious, including some of the shades of grey, tea colour, terra cotta, &c., there is nothing so truly artistic, refined, and pleasing in the long run as white. In recommending a white mount I would add that there should be a border around the print about a quarter-inch wide of India tint or some other insubordinate shade, which, though hardly visible against the white, adds greatly to the effect of the picture when mounted.

A few months ago I prepared some prints of different sizes, from 20×24 down to cabinet, for exhibition purposes, and mounted them as follows: The prints were toned to the black-and-white tone, mounted on ordinary black and white cardboard mounts, and bevelled, leaving no margin of mount whatever.

They were next mounted with glue on deep, cream-coloured, pebbled matt board. I next cut a matt out of pure white matt board, making the opening one inch larger each way than the bevelled print. This matt was mounted on the cream board so as to leave an equal border of cream colour half-inch wide around the print. The whole was then placed in a plain gilt frame, half-inch wide and without glass. The effect is not only exceedingly pretty, but is neat, and does not detract from the picture itself, which is always to be avoided.

Another mount which is very artistic and effective for the black tone is one of black. The print should be bevelled as before, and mounted upon the black cardboard, or, if for framing, the matt should be black, with a deep white bevel and a gold frame.

As I confine myself to the black tone, I have not been as observant of the effects for sepia, still I should again recommend the white mount.

A nice effect is obtained with sepia tone and sepia mount to match, but there must be harmonious blending of the two or the effect is entirely lost.

In using the sepia mount as above mentioned, there should be a narrow border of white between the print and the mount to give the best effect.

The matt prints should have wide margins about them; the margin of the ordinary cabinet mount for a cabinet print is not sufficient to show it to the best advantage.

In preparing pictures for the show-case, I think it would be difficult to decide upon any one background as the best, because where the pictures are changed the background should also be changed in order to make a complete revolution, which is the only way to attract the most attention. All of the backgrounds must be good and selected with great care, but each one should be different from the preceding.

In my present display the background is gold, produced by coating large sheets of matt board in the same manner as for gold matts. The prints are matt surface, toned black, which is the only kind I exhibit or make. They are mounted on cardboard and bevelled, then mounted on black cardboard so as to leave a border of black about three-quarters of an inch wide around the print. The whole is then mounted on the gold in the desired position. In addition to this the show-case is illuminated at night by twenty miniature incandescent lamps, and the whole effect is the most attractive of anything I have yet observed.

The show-case at the door is one of the photographer's best advertisements, and, as the advertising question is one which to a great extent absorbs the minds of merchants in all lines of business, I will give my opinion, gained from actual study and experience. I find that advertising pays, but there are modifications to that statement. The newspaper, programme, in fact, any of the established methods of advertising are

good; still, setting these one side, the pictures themselves are the best advertisements for the photographer. In no other line of business does the result of one's labour show to advantage or disadvantage, as the case may be, as in photography. If one makes twelve good cabinets for a customer, the supposition is that those twelve pictures go into twelve families, which means that you have proven directly to twelve families the quality of your work. *Good work* is by all means the *best* advertisement. The babies are the most satisfactory customers one has. There is very little to be done excepting to place the baby in some suitable chair, which can be covered by its clothes, focus, and then use your patience. Accessories do not improve babies' pictures. Get a good photograph of the baby, and you will surely please the parents and all its friends, which you will find is also an excellent advertisement.

One cannot do much to induce babies to assume a suitable expression; don't be in too much of a hurry, because, if the baby is left partly to itself, the expression will come, and be better than if the little one is worried. Oftentimes various sounds to which it is not accustomed will be a help, although I do not find it necessary to keep the operating room full of rattles, tin horns, &c.

I am asked for my opinion concerning Sunday work. I most *emphatically disapprove*, still I am obliged to keep open my studio every Sunday.

If one judged the value of Sunday work by the number of sittings, the conclusion would be that it paid. On the other hand, the people who say they can have their picture taken only on Sunday would not go without them, and if they could not get them Sunday would get them some other day. I will venture to say that seventy-five per cent. of such people find time during the week to attend a ball game or some other place of amusement.

There is no reason why a photographer should be obliged to work seven days each week.

The studio is confining, and to do one's best work an occasional rest is necessary. I believe every intelligent and progressive photographer should and would support a Sunday-closing law, and it is only through the efforts of the photographers themselves that this can be accomplished.

In this work the journals can be of great service, and it is on questions of this kind, as well as by articles on actual manipulation of different processes, that the journals are of actual value to the profession.

Every photographer should read the journals, for it is by this means only that he can have knowledge of what others are doing who are doing the best.

The photographer who never reads a magazine of the subject, who never goes to a Convention, is sure to discover at some time, sooner or later, that he is decidedly behind the times, and his business gone.

(2) By Herbert Randall, Ann Arbor, Michigan.

I will repeat your questions in their order, and answer in accordance with my judgment.

1. What do you consider the most effective colour for mounts used for matt-surface paper (*a*)? For dark tones (*b*)? For sepia tones?

For black tones, grey or white.

For sepia tones, a soft brown.

2. Do you favour small mounts or large ones for the usual cabinet size print?

For best effect I favour larger mounts than are ordinarily used for cabinet prints, but I do not believe in using them without an advance in price. I get two dollars a dozen extra for cabinets mounted on large mantello mounts.

3. What do you consider the best background for show-case displays?

I use garnet, black, or dark green velvet, or plush.

4. What class of work displayed attracts the most attention and the most dollars?

Portraits of familiar faces.

5. Does advertising pay, and what method is best?

A certain amount of judicious advertising pays, but I think much money is wasted in advertising. With me the best advertisement is a well-dressed window, kept fresh and clean.

6. What accessories do you use in photographing babies? How do you keep them in pose? What means do you employ to gain expression?

I use very few accessories. If you refer to six-month-old babies, it is "catch as catch can;" if two or three years of age, it's a difficult thing to explain. I talk into their eyes; they understand common-sense conversation better than older ones, often are so mobile and quick to grasp your thought that the cleverness of magnetism is usually sufficient; but, if it is a certain expression that the mother is after, you are about as sure of it as you are of catching the "lightning bug" that flits before you on a summer evening. I wish mothers could understand that, the more starched up the child is, the less poetry and childishness is impossible to obtain in a picture; their preparatory training is an obstacle; their "Do just as the man says" makes more trouble than it overcomes. The charm of child beauty is simplicity, every-day home apparel, bare feet, if it may be, without fuss and feathers.

7. Do you favour keeping galleries open on Sundays? Does it pay? Would you support a Sunday-closing Act, if made general?

I do not approve of opening places of business on Sunday. It makes no difference whether, from a financial standpoint, it pays or not; however, I believe it does not in the long run. I object as a matter of principle, but I have a class of trade which would denounce it. Then I believe no man is fit for work seven days in a week, and he ought to get both rest and inspiration, at church or elsewhere. There is no argument in its favour, spiritually or otherwise, based on good judgment. I am not a crank, and would accommodate a customer under special circumstances. I simply condemn the practice of general opening of a place of business on Sunday. I would not in any way interfere with my neighbour's affairs, yet I believe his disregard for the Sabbath retards the progress of civilisation. I try to live up to my own ideas of what is right; on this law all happiness is based. I honour manhood, and would not ask an *employé* to endanger his character by performing duties which I would not do myself. This is a consideration that every *employé* is entitled to. I believe that existence and happiness do not so much depend upon dollars and cents as some think they do.

8. Of what actual value to you are the photographic journals?

Both I and my workmen get inspiration from them.

I do not think that art theories are discussed enough therein.

The literature of æsthetics, criticisms, and contributions of a different order might be of value. The soul is developed by beautiful thought, and it is partly within the province of our art to furnish it.

The commingling and interweaving of refined ideas are means for elevating, and by these and the infinity of nature we are trained to higher things, being, as Hamerton says, "only something by the place we hold in the intellectual chain of humanity."

(3) By G. H. Fowler, Charlotte, Michigan.

1. Technically speaking, I would not like any coloured mounts for matt surface photographs; would prefer a light shade of drab or grey. I think a line of India tint to come between the margin and photograph would look well, especially with black tones. I like plenty of margin.

2. It depends on the shade or colour of mounts and tone of pictures. Black will do for almost any tone. Maroon and shades of drab and grey are good. Quite an effective and lasting background is made by stretching some burlap or any coarse cloth over a board and mixing up alabastine thick, then work in relief plastic designs, and while wet pouncing on gold bronze on prominent parts. Almost any shade goes nicely with gold.

3. It pays to exhibit the best work you can make, and not exhibit it very long at a time. A small show-case at the door, changed often, is a good thing. If you do large work and your studio is upstairs, and no one else uses the stairway, a good way is to fix up a sliding show-case to run down nights. Make it to fill up the entrance; use pulleys and rope weighted so as to make it run up and down easy, then put in a light—incandescent is the best—and exhibit your large work framed up and put in your case evenings. I have one, and exhibit a good many pictures during the year in this way. Your pictures are an excellent advertising medium. Spicy locals in newspapers pay; attractive bulletin boards in the country pay. Best of all, don't allow any poor work to leave your studio. Let Cheap Johns turn out that kind of work.

4. Any kind that will not attract the eye from the subject in hand, the baby. In portrait photography the background should not be remembered by those who look at the pictures. I like to get happy pictures of babies, and I always catch their smiles if I can, unless the mother objects to smiles, and very few do. Yes, I try for expression, have tried for an hour at a stretch before now, and sometimes have caught it, but it is better to have everything in shape and catch the expression quick. I have a raised platform to sit babies on who can sit up, then turn their feet around to one side or the other, never in front. They look as though they were sitting on the floor, and are quite satisfactory.

5. I do not favour Sunday work, and never do any except in extreme necessity. I would favour and support a Sunday-closing movement.

6. Journals are of great value, like conventions; exchange of ideas; more experience from workers who have had a "finger in the pie." I take five; yours makes six.

WOOD-ENGRAVINGS *VERSUS* HALF-TONE BLOCKS.

[An Extract from a Paper read at the Society of Arts.]

Wood-engraving, we are told by some people, is dying out, or will be one of the past arts before many years, and process or mechanical work by means of photography will take its place as a medium for illustrating books, magazines, and papers.

This is what we hear on all sides, and, if we look at the illustrations at present produced in most of the publications, it undoubtedly does appear at the first glance as if there were something in this almost universal opinion. But what is this so-called popular opinion? I think it only comes from readers who confine themselves to the sensational side of literature, and, not having their imaginations fully developed, want something beyond the letterpress to help them to realise what they are reading; *then* cheap art comes in to help the cheap publications, which are on the increase to such an extent, that process illustration looks as if it were taking everything before it.

But, by dipping a little deeper into the question, we find a very different state of things. We see that wood-engraving was never more alive as a fine art, or in a higher state of perfection, than it is at the present period; and it is still capable, in the hands of right good, earnest workers, of being lifted to a much higher position.

We may grant that wood-engraving has been superseded for a time, for

purposes of illustration, by process work, on account of the latter being so much more rapid, and also much—very much—cheaper. I will not say very much inferior, for it is unquestionably better than bad wood-engraving. And here I may say, I do not mean essentially bad work, but work that has to be done in a rush, such as war subjects, which sometimes have to be engraved in a few hours.

Yet, so long as the public are blind enough (blindness which makes one wonder, considering the art culture that is going on all over the country) to take bad, or rather, as some put it, "soft and delicate" kinds of illustration, instead of good art, both delicate and beautiful, so long will some publishers give them bad rather than good work, charge the same for the publication, and pocket the difference; and why not, if the public will be so foolish? Every opportunity is afforded them to distinguish the good from the bad; but they, or the majority of them, judging from the publications that pay best, prefer the bad to the good. Then, what happens? So long as this blindness or apathy lasts, so long will wood-engraving suffer in this particular department of publication.

But we have a much brighter side to look at. Let us leave behind the lovers of cheapness and speak to those who are lovers of art for art's sake. To them I say that wood-engraving, as a reproductive fine art, never can be touched, or ever will be touched, by any process yet invented. I am now speaking of all the mechanical processes at present being used for illustration. With regard to the higher or fine-art processes, I hope to show further on that wood-engraving is far and away above any of them in its marvellous versatility of technique, which enables the engraver to translate not only the values, but the very individual touch of each artist, from whose picture he may be engraving.

All processes dependent upon photography are bound to go wrong in the rendering of values, since photography has not yet been brought to such a state of perfection as to master the difficulties of exact colour translation. In fact, photography is utterly inadequate in the most simple wash drawings in black-and-white. For instance, a drawing executed in black, no matter what black, when Chinese white is used mixed with the black, will come out, as a whole, entirely untrue as to values in the process block, because of the brown in the black and the blue in the white. The slightest difference in the admixture of the two colours will be entirely mistranslated, although the drawing may look perfectly right as to the values to the eye.

Even in a pure wash drawing, without the use of Chinese white, the paper drawn upon being more or less yellow, the high lights that are left are lower in tone in consequence.

Take any process, and, if you have an intimate knowledge of the original painting or drawing from which the process plate has been done, you will see at once how very far short it falls of the original. All the spirit has departed from it—it is weak and insipid. Indeed, although photography has made great strides in late years, it has not yet been able to get over its main difficulty, values, and I must say that I do not see at present how it can get over it. No process plate that I have ever seen, either from a painting or a black-and-white wash drawing, has had a pure black, or a properly gradated white, which is as much as to say, it cannot carry out the most simple rules of translation of values. But I admit with pleasure that a pen-and-ink drawing in pure black ink could hardly be reproduced in a better manner than by the best process. I say the best, as I only now and again see a very fine line reproduced thoroughly well by process. As a rule it is either broken or thicker than the original, and thus loses its value. But, beyond this, I most emphatically assert that nothing does or ever can compare with the work done through the sensitive medium of the eye and hand of man. In fact, I consider wood-engraving far better than any or all the reproductive arts, as it stands quite alone in its wonderful adaptability; for any variety of texture one likes can be produced on the boxwood block. This cannot be said for either etching, mezzotint, steel or copper, each having its own methods, great as the masters have been who have worked upon one or the other of these materials; and, as far as I have seen, they never have departed from the original mode of treatment, peculiar to the material they worked upon. Thus, they have necessarily missed the individuality of the painter they translated, the reason, of course, being that the material will not lend itself to variety of treatment.

Now, with regard to wood-engraving on boxwood, any texture you like can be engraved upon this material, it is so adaptable; but it requires an artistic engraver, not a mechanic, to arrive at anything like good results. Happily, at the present time, we have plenty of right good artistic engravers, not only here in London, but all over the world.

The crowning advantage enjoyed by wood-engraving, through which it obtains its immense superiority over all other methods, is that the engraver is enabled to work in both black-and-white line. This, in the hands of an artistic engraver, one who knows his work, and, beyond that, loves it, is a most valuable power.

Nothing is out of the range of imitation possible to wood-engraving. The differences of texture of flesh, silk, satin, cloth, wool, steel, glass, the grain of wood, marble, weather-worn stone, furs and skins of animals, atmospheric effects, foliage of all kinds; all these it can represent, and, beyond everything, it can render the differences between oil and water colour, and can accurately transcribe the old master's work with all its cracks and blemishes from damp and shrinkage. It has been said by some that the old masters cannot be rendered in this way except by photography.

W. Biscombe Gardner.

JOLY'S METHOD OF MOUNTING AND STORING TRANSPARENT PHOTOGRAPHS.

Dr. Joly states that the object of his invention is to mount transparent photographic pictures on glass, or celluloid, or other transparent material, whether positives or negatives, in a book or album, and so that they can be readily inspected by transmitted light. The leaves of the album are perforated through and through with openings of the required size to receive the plates. Alternate leaves are blank and of white card or other white or reflecting material, so that light reflected from this surface enables the photographic transparency to be seen by transmitted light as the leaves are turned over; or the alternate blank leaves are omitted and a single white leaf or reflector provided, which can be inserted anywhere in the album to reflect light through the pictures on the adjoining page of the album.

MORA'S PROCESS FOR THE REPRODUCTION OF OIL, WATER, AND WATER-BODY COLOUR PAINTINGS.

Sig. G. Mora's invention relates to the reproduction by mechanical means of oil or water-body colour paintings which may, at pleasure, deal with historical or religious subjects, represent landscapes or other views, or be used for advertising purposes, for the preparation of topographical plans or geographical maps, for imitating carpets or tapestry, or for the reproduction of serial views (or copies thereof), also of book covers, frontispieces, or the like; all of which reproductions or representations it is proposed to obtain by the superposition of transparent colours upon the layers of colours used in the original to be reproduced, no matter whether these are oil colours, water colours, body colours, or honey colours, or whether they are coated with varnish, size, or gelatine, the various reproductions, upon cloth, paper, wood, metal, ivory, or the like, being so carried out, that they present accurate copies of the originals—no matter whether of old or recent creation—rendering every detail of the model copied from, every stroke of the pencil or brush, and giving even a notion of the relative thickness of the several layers of colour applied, so that the appearance of the picture having actually been (hand) painted is fully kept up.

This result is obtained by the following method:—

After a suitable support, such as paper, canvas, wood, metal, or the like has been selected, that which may be called a "preparatory" coating is applied thereto; for which purpose a layer of an insoluble mixture, damp-proof and impervious to water, composed of salts of chromium, for instance, bichromate of ammonia, bichromate of potassium, chromic acid, mixed with a watered solution of fish jelly, gum, glue, or the like, making such solution an insoluble one in water, when smeared on a surface exposed to the light, is spread over the support by means of a brush, preferably made of the tail of the hake or salt cod, or simply by hand, or by a suitable mechanical contrivance, according to requirements, or to the nature of the support or of the original to be reproduced. When this is done, the back of the support to be printed upon is covered or lined with paper, or with thin metal plates, as the case may be, such lining or covering being fixed thereto by starch paste, so that a species of stiffening surface is formed for the time being, though it is subsequently (upon the completion of the work) removed by the aid of steam. Now a tracing is taken of the model to be reproduced—which may be the original picture, or a copy or photograph of the same—the operation being the same as that usual in chromo-lithography. This tracing (or positive photographic impression) is then transferred to cardboard, rendered insoluble or water-resisting, or to thin metal sheets, or, indeed, to sheets or veneers of wood, also rendered impervious to water; and these sheets (whatever the material they consist of may be) are converted either by hand, by a chemical process, or by means of a cutter, used while the sheets are dry, into as many open or perforated patterns as may be required to reproduce the several layers or thicknesses of colour, with their different tones or shades, each of such patterns corresponding to a portion of the original, painted a given colour. The support employed (viz., the paper, canvas, wood, or the like), whereon the tracing (or photographic impression taken on the preparatory coating) is applied, is then mounted in a suitable frame.

Upon this support there is then adjusted by means of marking points or pins, one after another in succession, as many patterns as there are different colours in the original requiring to be reproduced, there being one pattern for each of the main colours or shades; after which the corresponding colour is applied to the copy (through the pattern or stencil) by means of suitable brushes, by hand, or by means of special machines fitted with brushes. The colour or ink employed for this purpose should be mixed with a sufficient quantity of a suitable siccative, while in all other respects it should correspond to that of the original, no matter whether such original was painted in oils or water colours or the like, and whether or not it was sized or varnished; and, as in the case of the original, the colours to be used for the copies may be prepared with honey, gelatine size, oil, or the like.

When the principal shades of colouring have thus been reproduced and a complete solid layer of colour formed, and after every stroke of the brush, appearing in the original, has been rendered, with its relative size or thickness (which is seen to before the colour has become quite dry), the well-dried copies are coated with varnish containing alcohol; and then the reproduction of the half-tints is proceeded with.

In order to obtain the half-tints, it is necessary, first, to prepare a photo-isochromatic copy of the picture to be reproduced, which should be transferable by the ordinary means or methods now in use, such as photo-lithography, photo-typing, photo-engraving, or the like, and such copy is then transferred to stone, metal, or gelatine.

These half-tints are then so displayed that, both in design and in value or strength of tone, they are exactly in keeping with the corresponding half-tints of the original; which result is accomplished by chemical processes such as helio-typing, chromo-typing, and the like, and by touching up the picture with a pen, pencil, or graver.

To print the half-tints, impressions, previously obtained upon zinc, copper, stone or gelatine, with ink such as has been above suggested, are resorted to, care being taken to render the said ink transparent; or such ink as is ordinarily employed for lithography or printing generally may be used, plane or roller printing presses (preferably with india-rubber rollers, such as are in use for printing upon sheet metal) being adopted; or printing presses or machines, as used in ordinary typography or lithography, may answer the purpose; or machines, suited to the special requirements of each case, may be specially constructed, the choice of the machinery to be employed depending to a great extent upon the nature of the "support" adopted for the reproduction of the copies.

When the semi-tints have thus been applied to the coloured ground-work, obtained by the aid of the patterns or stencils (which groundwork, may, however, have been produced through the medium of photography, or simply drawn or painted by hand, if preferred), the copies are allowed to dry in a convenient desiccating chamber. After this, the said copies are varnished, so as to raise the tones of colouring into due prominence, whereupon the tracing of the original is again printed, care being taken to sprinkle over it colour which is soluble either in water, alcohol, or petroleum. This tracing serves as a reliable guide for the ultimate touching up, which should be performed by hand, *i.e.*, with a brush, and the object of which is to "finish" the copy, so as to carry the identity between it and the original to perfection.

The last tracing is then removed at the points where this has not been done in the retouching operation; for which purpose a sponge, soaked in water, alcohol, or petroleum, should be used; and the final coat of varnish is eventually applied as is usually done in the case of oil paintings; while, where water-body colour paintings are to be copied, albumen may be employed for the purpose of varnishing.

In some cases, the preparatory operations may be performed simply with a brush, by hand or machinery, and with patterns or stencils, upon a tracing to be finished with a brush by hand; this would specially apply where a large number of copies is not required. The final result obtained by this method will prove positively astonishing in its realism, as it will in a most remarkable manner keep up in the observer's mind the illusion of its being an original hand-painted image or design.

The Inquirer.

*** *In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* JOURNAL *useful and instructive.*

CEMENT FOR GLASS AND PAPER.—CIMEX says: "Can any fellow professional give me a reliable recipe for a cement or paste with which to attach labels to glass? I am in the habit of attaching a label to each of my negatives begore storing them away, and I usually keep them for some weeks on a shelf in the printing room, in case they may be wanted before final storage. The room is always kept warm by means of a stove, and it is annoying to find a large percentage of the labels detach themselves apparently through excessive dryness. I have tried a lot of preparations containing glycerine, sugar, and similar substances, but have not yet hit perfection. I shall be greatly obliged if any of your readers can help me."

CLEANING OLD NEGATIVE GLASS (To W. Howard) — The best way that I have found to clean old negative glass is: The old negatives should be put together in water; water which has a little ordinary washing soap dissolved in it is preferred. Procure a piece of Brookes's soap, and, with a piece of wet rag rubbed on it, apply it to the film, or the bar of soap itself may be used instead. In a short time the film will blister, and can easily be stripped off the glass without the least trouble.—T. MATHIAS.

GREEN FOG (To "Eder Emulsion").—Although the presence or absence of green fog will be influenced to some extent by the character of the gelatine, it is quite possible either to have it or to steer clear of it with one and the same sample. Much more depends upon the temperature employed, for it must be borne in mind that ammonia or any other alkali, in the presence of gelatine at a temperature very little above 100° Fahr., acts as a reducing agent towards silver salts. On this account most gelatines will give more or less green fog with the ammonio-nitrate method of emulsification. As regards the commercial use of this method, it is probable that the immunity from green fog in most of our best brands of plates is due to the employment of the centrifugal separator, which, in removing the decomposed gelatine, also removes the "dye" which is supposed to cause the dichroic fog, as well as the coarser particles of silver which go to form ordinary grey fog.—SYNTAX.

WET PLATES AND ALKALINE DEVELOPMENT. — A BEGINNER IN WET-PLATE WORK writes: "I have read somewhere, recently, of a method of intensifying wet-plate negatives, after ordinary silver development, by means of alkaline pyro, and I have also been told that it is possible to develop wet plates in the same manner; but, having tried both plans, I have signally failed to arrive at any result but a hopeless mass of fog. Naturally, I can understand the importance of removing the free nitrate of silver from the collodion film before applying the alkali, but I do not think it can be the neglect of this that has caused my failure, as I have been careful to wash very thoroughly before proceeding either to develop or intensify, but still the fog comes. Can it be that for such treatment the bath requires to be in a special condition as regards acidity, or perhaps of alkalinity? My trials have been made with ordinary bromo-iodised collodion (Mawson's) suitable for iron development."—In reply, there is no reason why a wet plate, that would develop properly with iron, should not also behave in the same manner with alkaline pyro or any similar development, provided the film be first rigidly cleaned of all free silver; but this is an operation that requires more than a mere perfunctory surface washing. After a copious rinsing in plain water, the plate should, for safety's sake, be flooded with a weak solution of common salt, and again rinsed, when it is scarcely likely that any free nitrate will remain. This can be done either before or after exposure, or, in the case of intensification, after the first development.

RECOVERING SILVER FROM HYPO SOLUTIONS. — THEO asks with reference to our recent leading article on *Experiments upon Hypo Residues*: "What is the best metal to use for the purpose of precipitation?" He goes on to explain, "I do not like liver of sulphur—because for want of space I am obliged to keep my residue tank in any ordinary workroom where I have to do my toning and fixing, and, in fact, perform all my photographic work. The stuff itself is sufficiently unpleasant, but I imagine the fumes given off must be actually dangerous to any sensitive films, whether plates, paper, or carbon tissue, that may be exposed to it, and I should therefore prefer to use one of the metals as the precipitant. But which?"—In reply: Zinc, copper, or iron, may be used indiscriminately, and, assuming that the precipitate is to be subsequently sent to the refiner, it matters little which is chosen, as all of them cling with more or less tenacity to the precipitated silver, and each requires special treatment for its thorough removal. If, on the other hand, the silver is to be converted into nitrate by the photographer himself, we should say, use zinc, because although at least as difficult of removal as the others, the presence of a slight trace in the resulting nitrate would be perhaps less objectionable than either copper or iron. Our correspondent must, however, bear in mind that, even when any of the metals are used for this purpose, considerable quantities of sulphuretted hydrogen are given off, and he will be wise to transfer his residue jar to the open air, where, in all probability, the objection to liver of sulphur will disappear.

Our Editorial Table.

CATALOGUE RECEIVED.

Newman & Guardia, 92, Shaftesbury-avenue, W.

THIS is the height of the hand-camera season, and therefore an appropriate time for the appearance of Messrs. Newman & Guardia's catalogue—as handsome a production of its kind as we have seen. The various patterns of the "N. & G." hand cameras are fully described, and other sections of the catalogue treat of the accessories of those cameras—changing boxes, shutters, stands, and other items of apparatus that Messrs. Newman & Guardia specialise. Excellence of get up and printing distinguish the catalogue, which is adorned with a number of photographic reproductions from negatives made in the "N. & G." cameras. The quality of these pictures is superb, and altogether the catalogue exemplifies in the highest degree the capabilities of the typographic art.

THE HALF-TONE PROCESS.

By JULIUS VERFASSER. Bradford: Percy Lund & Co.

A SECOND edition of this excellent little treatise has been issued. In the sections devoted to negative-making, printing, and etching, much new matter has been added, the author having taken account of the progress that has been made during the past year towards the use of collodion emulsion and gelatine plates. Other and minor additions have also been made to the book, which has deservedly won a permanent place as a clear and reliable exposition of half-tone theory and practice.

LUND'S DIRECTORY OF PHOTOGRAPHERS, MANUFACTURERS, DEALERS, &C.

Bradford: Percy Lund & Co.

THE ground covered by this *Directory* includes England and Wales, Scotland, Ireland, the Isle of Man, Europe, Asia, Africa, North and South America, and Australia. The information is given under the heads of the various towns, and also alphabetically, and it comprises the names and addresses of those who are dealers, enlargers, picture-frame makers, lantern specialists, manufacturers, and professionals and dealers. The *Directory* has evidently taken a good deal of trouble to compile, and should prove useful to many.

NEW GROUND IN NORWAY. WITH FIFTY-SIX ILLUSTRATIONS FROM ORIGINAL PHOTOGRAPHS BY PAUL LANGE.

By E. J. GOODMAN. London: George Newnes (Limited).

SOUTHERN Norway is the "new ground" over which Mr. Goodman takes the reader. He describes it as that part of the country which lies between Christiansand and Christiania, and extends from the coast inland for from 50 to 150 miles. Southern Norway, unlike the more familiar west and north, is said by Mr. Goodman to be a land of lakes and rivers, forests and mountains. It is essentially a green land, richly fertile in timber and foliage, possessing, so to speak, a clothed wildness, in striking contrast to the more naked savagery of the North. From Christiansand the author pleasantly leads us through a charming and unconventional country. The inhabitants are as interesting, primitive, and agreeable as their surroundings are beautiful, and Mr. Goodman's account of both is attractively written. *En parenthèse*, he has some piquant things to say of Dr. Henrik Ibsen, of whom a portrait is given. There are about sixty illustrations from Mr. Paul Lange's negatives. The reproductions (in half-tone) are well done, and it goes without saying that such a skilful worker as Mr. Lange has not fallen below his reputation. Each view is a picture, and the costume studies are quaint and fresh. It is altogether a delightful book.

THE ELEMENTS OF A PICTORIAL PHOTOGRAPH.

By H. P. ROBINSON. Bradford: Percy Lund & Co.

MR. ROBINSON'S book is thus dedicated: "To my brothers of the Linked Ring, whose efforts have done much towards saving the art of photography from extinction;" and its object, in the author's words, is to help the amateur to recognise that there is much more in the art than the taking of a simple photograph, that its materials are only second in plasticity to those of the painter and draughtsman, and that, if they are more difficult to manage, there are effects to which they are even more adapted than other means of art. The chapters on "Models," "Foregrounds," "The Sky," and "The Sea," illustrated as they are by examples of Mr. Robinson's own work, are probably those that may be read with the greatest direct profit by the photographer, as they are full of sound teaching clearly exposed. Some of the sea pictures, by the way, are very badly reproduced, but the other illustrations are well done, and the book is entirely one whose ripened ideas on pictorial photography give one plenty to reflect upon.

News and Notes.

MESSRS. MARION'S Annual Stocktaking Clearance Sale will commence on July 1, and terminate July 10.

WE are sorry to learn of the death recently of Mr. Henry Jackson, who was in business many years at Fishguard as a photographer.

COLONEL GEORGE HOPE LLOYD-VERNEY, late of the 3rd Battalion of the Hampshire Regiment, died at Clarens, on the Lake of Geneva, on Sunday week, at the age of fifty-four. He was formerly a member of the Photographic Club.

THE Stereoscopic Society, under its recently revised rules, is now prepared to admit four fairly advanced workers, ladies or gentlemen. Full particulars may be obtained from the Secretary, B. Diseri, Huntly, N.B. Early application is desirable.

THE PHOTOGRAPHIC CLUB.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, July 1. Subject for discussion, *The Relative Merits of Different Intensifiers*. The date of the Club outing has been altered from June 27 to Saturday, July 4. Full particulars are announced elsewhere. Letters of inquiry may be addressed to Mr. Gotz, 215, Shaftesbury-avenue, W.C. Visitors are welcome.

PHOTOGRAPHING THOUGHT.—In his communication to the Académie de Médecine, Dr. Baraduc relates that Dr. Istrate, when he was going to Campana, declared he would appear on a photographic plate of his friend, M. Hasden, at Bucharest. On August 4, 1894, M. Hasden, at Bucharest, went to bed with a photographic plate at his feet, and another at his head. Dr. Istrate went to sleep at Campana, at a distance of about 300 kilometres from Bucharest, but before closing his eyes he willed with all his might that his image should appear on the photographic plate of his friend. According to Dr. Baraduc, that marvel was accomplished. Journalists who have examined the photograph in question state that it consists of a kind of luminous spot on the photographic plate, in the midst of which can be traced the profile of a man!

SOCIETY OF ARTS. PRIZE FOR INDUSTRIAL HYGIENE.—The Council of the Society of Arts are prepared to award, under the terms of the Benjamin Shaw Trust, a gold medal, or a prize of 20*l*. The medal, under the conditions laid down by the testator, is to be given "for any discovery, invention, or newly devised method for obviating or materially diminishing any risk to life, limb, or health, incidental to any industrial occupation, and not previously capable of being so obviated or diminished by any known and practically available means." Intending competitors should send in descriptions of their inventions not later than December 31, 1896, to the Secretary of the Society of Arts, Adelphi, London, W.C. The Judges will be appointed by the Council. The Council reserve the right of withholding the prize or of awarding a smaller prize or smaller prizes, if in the opinion of the Judges nothing deserving the full award is sent in.

ON reading about the new X rays, our Egyptian correspondent, whose silence hitherto we all deplore, writes to say that, having armed himself with a brand new Cook's tourist camera, an Italian induction coil, and a Crookes' tube, he approached the Sphinx with a view to penetrate the brain of that most ancient of oracles, and find out the why and wherefore of these dispatches of Indian troops to Suakim. He was received with characteristic inscrutable calm and dignity. On developing his plates, he was surprised to find not only an accurate delineation of the features of the oracle, but, strange to say, through some reflected light in the half-closed eye of the monolith, an equally admirable picture of himself as he focussed the scene before him. Unfortunately, the rays brought to bear on the Sphinx were powerless to throw any light on the *raison-d'être* of the Suakim expedition, although the expression on its features so admirably brought out by our esteemed correspondent was, to say the least of it, suggestive. He adds that he means to have another attempt, and hopes to be more successful.—*Journal of the Photographic Society of India.*

"SATISFACTION GUARANTEED."—"Satisfaction guaranteed" means that one will make sitting after sitting until all the whims of some unreasonable sitter have been exhausted, and even then satisfaction not be found. The photographer should do his best at all times. This is all that should be required. The samples should be an index to the quality of the work done. "One must compete with his own samples," says Mr. J. R. Swain, in the *St. Louis and Canadian Photographer*. "The customer should expect the work to equal the samples displayed, nothing more. If resittings have to be made on account of the hair or clothing, they should be charged for, especially if the fault was in the customer. I have known parties perfectly pleased with their pictures till some old crone called their attention to some little defect in the hair or clothing that did not amount to anything or injure the pictures in the least. But, if satisfaction is guaranteed, the work is all to be done over again. It is sometimes a good plan to give these self-styled art critics a broad hint by asking them to make the resitting for you. One such hint is generally enough. It is one thing to satisfy a customer; it is quite another thing to satisfy the whole family and all their connexions. It is well to have an understanding with the sitter at the beginning, that her picture shall compare favourably

with the samples displayed; nothing more should be promised. If your samples are not satisfactory, better let her go somewhere else. Keep up the dignity of the profession by not promising too much, and making good all that is promised."

COPYRIGHT IN PHOTOGRAPHS.—In the Queen's Bench Division, on Monday, Mr. Justice Cave and Mr. Justice Wills, sitting as a Divisional Court, had before them the case of Guggenheim and Another *versus* Leng & Company. This was an appeal by the plaintiffs, who carry on business as photographers in the Midlands, against a decision of the County Court Judge of Sheffield. Plaintiffs sued in respect of an infringement of a copyright of a photograph by the defendant newspaper proprietors of Sheffield. The photograph was that of the Wolverhampton Wanderers' football team, and permission was given to the defendants to use this in a a paper issued by them called *Sports*. The photograph was issued as a supplement, and not in the body of the newspaper. A number of the photographs, however, were sent to Wolverhampton, and sold separately from the paper. The County Court Judge held in favour of the defendants in this instance, but in another case, in which the heads of the players were reproduced and published in defendants' journal, *The Week*, the County Court Judge found for plaintiffs, and awarded 1*l.* damages, to avoid the expense of a new trial. The Judge was asked to assess the damages in the case of *Sports* if he was held to be wrong, and 20*l.* was fixed by him. Plaintiffs now asked for judgment to be entered in their favour for 21*l.* Their Lordships now held that, though defendants were right in publishing the photograph as a supplement to *Sports*, they had no right to issue it separately, and in this respect the County Court Judge was wrong. Their Lordships reversed the decision in favour of plaintiffs for 1*l.* in respect of the drawing of the head of the players in *The Week*. Judgment was then entered for plaintiffs for 20*l.*, with costs.

"I BELIEVE I am correct in stating," says Mr. Martin R. Cobbett in a contemporary, "that an eminent Cameranian made a long and perilous journey into the wilds of Wiltshire with intent to acquire a counterfeit presentment of Mr. Fulton's mare Laodamia, charming daughter of an, if possible, more perfect mother. His reception was very old Irish in more senses than one, but it began and ended with ancient Irishism; photographing was out of the question. So the ambassador accredited to the court of Fulton came empty away—in at least one respect. Which reminds me that I once was similarly baffled when endeavouring to take or procure the taking of another eminent Irish racer—no less a one than Lord Marcus Beresford. I laid on an artist who could sketch closely enough to the real thing or person if he had a fair chance. All he wanted was to get his subject to be still for a few moments. Lord Marcus, then Jockey Club starter, was approached by stealth on the Rowley Mile. His Lordship tumbled to the artist's game, and figuratively tumbled him over completely, for, like the 'plaguy old woman' of nursery rhyme fame, he would never keep quiet till he chose. My emissary thought to fix him up between the races; this was on a lovely warm day in spring. But he reckoned without his study, who bustled about from one starting post to another, and all the while he had a field in hand. Then, directly they were off, Lord M. played at taking a snooze on the turf, with his arms for pillows. All we got was a most truthful pencil picture of his Lordship's heels and the back part of his trousers, dorsal developments and shoulders, with, as headpiece, a billycock that covered even the back of his head from observation. We had views of the starter from the north and south, the east and west—admirable studies in full length, broadside on, and fore and aft, with true foreshortening effects; but our journalistic enterprise did not go to the extent of publishing these as likenesses of Lord Marcus. So we confessed oursalves beaten, and did no publishing at all, so far as he was concerned."

AN Exhibition has been given in New York of the results of the new discovery that, by coating the inside of a Crookes' tube with a fluorescent substance, it can be made to give a light comparable to that of an incandescent lamp when an electric current is passed through it. The tube in which the light is produced is an ordinary Crookes' tube, about four inches long and an inch and a half in diameter. The peculiarity of the invention is the coating of the interior of the tube with crystals of a newly discovered mineral that possesses fluorescent properties in a higher degree than the tungstate of calcium. Mr. Edison refused to tell what the mineral is, except that it is abundant and very cheap. The crystals are introduced into the tube and fused to the inside of the bulb. When the current is turned on from the Rhumkorff coil, instantly the tube glows with a pure white light. Mr. Edison says that the X rays are entirely absorbed by the fluorescent crystals, and that the closest tests fail to show their existence outside of the tube. So far, Mr. Edison has only made these lamps of about three and one-half or four candle power. He has now to find a way of producing the light from a direct current without the Rhumkorff coil, and to work out the commercial side of the problem. Some remarkable results have been found. One is that the electrical energy is transformed into light with hardly any heat, and the other is the remarkable conservation of the energy and the great economy of the new light. When Mr. Edison first reached his results, and took the tests by the ammeter and the voltmeter, he could not believe the figures, and sent for other instruments. These gave the same results, and, still to make sure, a third set of testing instruments was brought into use. These only confirmed the original records. The record showed that the new light was produced with the expenditure of only thirty-nine foot pounds of energy per candle power, a marvellous showing when it is remembered that the ordinary incandescent lamp requires about 150 foot pounds of energy per candle power. In other words, one horse power would run 846 of these lamps. The light is pure white, resembling clear sunlight, and has none of the moonlight effect. Tests with the spectroscope show that there is the normal amount of red in the new light. Mr. Edison is confident that he can succeed in reaching the commercial result by eliminating the Rhumkorff coil. He says that he has a new device that he has been working at that will change the ordinary current into one of the enormously high voltage needed with the low amperage. The coil that Mr. Edison is using in these experiments gives a current of from 40,000 to 50,000 volts, while the amperage is hardly measurable. He has tested the new lamps in multiple arc circuits, and finds that they work well together. He is now engaged in test experiments on the endurance of the bulbs, and, in connexion with this, is tackling the commercial end of the problem. He told a *Tribune* reporter that he believed that he would reach the desired end, but that it would be only after a long and costly analytical process. He said: "Of this you are as competent as I am, for it is something that no one can foresee."—*New York Tribune*.

A PRACTICAL ENLARGING PROCESS FOR THE AMATEUR AND PROFESSIONAL.—For many years, at convenient moments, I have experimented to ascertain the very best method to be used for enlarging negatives. There are many times when, in the case of friends passing away, we find only some small pictures, the result of random snap-shot, out-of-door photographs, which, of themselves, are not satisfactory. When the negatives of such pictures exist, a result can be obtained by the process I will describe, which is surprising even to an expert. The method hitherto in use, when the negative proved available, was to print a glass positive by superposition or in contact with the negative, and from the resulting positive—which, of course, is the size of the original negative—make an enlarged negative through a camera. This has always been against my conviction, as it seemed as if the grain, the retouching, and all the imperfections and striæ of the glass were proportionately enlarged and reproduced without remedy. But, as it was the generally accepted method in use abroad, and especially in the large (carbon) establishments in London, it was accepted. Of late, I reversed the operation by first making a full-timed positive the exact size desired for the enlarged negative. The amendments, improvements, and changes that can, at this stage, be made are remarkable. Upon the perfection of this positive and the work thereon depends the success in the final result. Let this positive be very carefully retouched and improved, as already suggested. When done, place it in a printing frame, of course with the glass side out, and in perfect contact with a dry plate. Back plate with black cloth or felt to prevent halation, and expose it at the distance of, say, 4 feet from a 6-foot burner two or three seconds, depending upon the vigour and strength of the positive. I usually expose and develop a small (4 × 5) plate as a test of the proper time. If all is carefully done, the resulting negative will compare favourably with a negative made from life. When a small negative, especially a portrait, is made with the intention of making an enlarged negative, the sitter should be well away from the camera, the latter having as large a lens as is practicable. For instance, if one possesses a 3A Dallmeyer, the ordinary cabinet negative will be nearer to correct perspective (there is perspective in portraiture) and proportion than if taken with a 3B or smaller lens. An 18 × 22 negative, recently made in the above manner from a cabinet of Mrs. Maud Ballington Booth, compares very favourably in all respects with any negative in my establishment taken direct from life. That the perspective and proportion are better and the distortion less goes without saying; but "that is another story," to which I hope soon to give attention. Finally, let all the steps in the process be carefully made, even to the dusting off and cleaning the uncoated sides of the original negative. Let the positive be somewhat vigorous, but full of detail and modelling. When dry, there is a fine opportunity for the tasteful, careful retoucher to not only remove imperfections, but to much enhance many details all through the picture. Lights may be accentuated and shadows darkened. —GEORGE G. ROCKWOOD, in *Anthony's Bulletin*.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

June.	Name of Society.	Subject.
29.....	North Middlesex	Informal Meeting.
30	Birmingham Photo. Society ...	Excursion: Stokesay Castle, Shropshire. Leader, C. S. Bayntun.—Last Day for sending in Competition Pictures for May Excursions. Warwick and Sutton.
30.....	Hackney	*Focussing*. W. E Debenham.
July.		
1.....	Borough Polytechnic	Open Night.
1.....	Croydon Camera Club	Excursion: Hatfield House. Leader, The President.
1.....	Photographic Club	The Relative Merits of Different Intensifiers.
4.....	Ashton-under-Lyne.....	Excursion: Lichfield Cathedral. Leader, J. W. Kenwerthy, J.P.
4.....	Borough Polytechnic	Excursion: Epsom Downs.
4.....	Hackney	Excursion: River Stort. Leader, H. W. Dunkley.
4.....	Liverpool Amateur	Excursion: Knowsley. Leader, W. Tomkinson.
4.....	Oldham	Excursion: Miller's Dale. Leader, B. J. Holt.

ROYAL PHOTOGRAPHIC SOCIETY.

JUNE 23,—Technical Meeting,—The Earl of Crawford, K.T. (Vice-President) in the chair.

COLOUR SENSITIVENESS OF ORDINARY PLATES.

The HON. SECRETARY (Mr. Chapman Jones) read a *Note on the Sensitiveness of Ordinary Plates to the Less Refrangible Light*, and showed the results of experiments made with the colour screens recently exhibited to the Society by Mr. F. E. Ives, confirming Mr. Ives's conclusions, and proving also one or two additional points. On each plate he had photographed the flame spectrum of the double carbonate of potassium and sodium without the interposition of any screen, and the results showed that the visually feeble violet lines of potassium came out very strongly, and were much over-exposed, while the

visually strong sodium lines sometimes showed quite distinctly, but, on other plates, they were very weak, though always present. Other slides illustrated the results obtained by the use of an ordinary Argand gas lamp, and with colour screens made with chrysoidine, aurantia, multiple yellow, and brilliant yellow.

Colour-screen Making and Testing.

Mr. F. E. Ives gave a practical demonstration of colour-screen making and testing. Given suitable facilities and conditions for the work, he thought the best method was to coat patent plate glass with gelatine, and, when the film was dry, immersing in an aqueous solution of the dyestuff until a quantity sufficient for the purpose was absorbed, and afterwards cementing the plate to another piece of patent plate by means of Canada balsam. Unless, however, the necessary facilities and conditions were available, there was great difficulty in preventing dust, &c., settling on the gelatine before it was set, and the moisture present in the atmosphere also militated against the production of satisfactory screens. The method which he had made use of for many years, and which he now demonstrated, was with collodion films. For this purpose it was necessary to employ patent plate glass, with plain surfaces, as nearly as possible parallel to each other, selecting the glass by taking the reflection of a distant gas flame, when only one image of the flame would be visible if the surfaces were perfectly parallel, while, if the glass was prismatic, two flames would be seen, increasing in separation with the degree of want of parallelism in the two surfaces of the glass. Unless one wished to make a number of screens, it was sufficient to coat the plate first with plain collodion, and then with an alcoholic solution of the dyestuff, drain it on absorbent paper, and allow the film to dry spontaneously. If, however, the colouring matter had been tested, and several screens were to be made, the better plan was to mix the dyestuff with the collodion, and coat by one operation. The films were sometimes liable to blister, but this could be obviated by first coating the glass with albumen. The plain collodion should be made with a cottoa giving a tolerably structureless film, and, when set, a nearly saturated solution of the dyestuff should be flowed over the film two or three times, and then drained off by means of blotting-paper, the operation being carried on in a dry room to avoid the absorption of moisture, which caused minute pimples in the collodion. When he had tested the dye, and knew that he had what was wanted for the purpose in view, his practice was to make a coloured collodion, for eight ounces of which he took four ounces of an alcoholic saturated solution of the dye and forty grains of pyroxyline, to which was added, after shaking, an equal quantity of ether. To make screens of a lighter colour, plain collodion could be added to the coloured collodion until the desired effect was produced. Some difficulty had been experienced in obtaining the brilliant yellow which he used for screens, but Mr. Cadett had found that it was supplied by Messrs. A. Leonhardt & Co., of Mühlheim, near Frankfort-on-Maine. When dry, the plates were coated with a varnish of mastic dissolved in benzole, cemented together face to face with Canada balsam, and bound round the edges with gummed paper. Mr. Ives made several screens by the methods referred to, fully describing the various operations involved, the dye used being brilliant yellow, and he tested one of them against a screen made with multiple yellow and having visually almost exactly the same appearance. The first object of a colour screen, he said, was to cut out the invisible ultra-violet and the dark violet rays, and at the same time to greatly reduce the action in the blue, and the most effective test was to expose an ordinary plate through the screen and a piece of pot yellow glass and a piece of cobalt blue glass, and, if in the result the cobalt blue was as dark or darker than the yellow, one might be sure that the dark violet was cut out by the screen, which was the essential point to be determined. The two screens were then tested in this manner by exposure to an electric arc light, and the result showed that the brilliant yellow one fulfilled the requisite conditions, the multiple yellow screen allowing the cobalt blue to photograph lighter than the yellow.

A discussion of a conversational character took place while Mr. Child Bayley developed the test plates, and, a hearty vote of thanks having been accorded to Mr. Ives, the meeting concluded, bringing the present session of the Society to a termination.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

June 18,—Mr. T. E. Freshwater in the chair.

A discussion took place as to the appointment of two delegates to the Leeds Convention, and it was pointed out that for some years no delegates had been officially recognised. Eventually it was moved that no delegates be elected to represent the Association this year; but, on being put to the meeting, this was defeated. The meeting therefore proceeded to vote for two representatives, with the result that Messrs. A. L. Henderson and W. D. Welford were elected.

Professor Stebbing, of Paris, who asked about the progress of photography in France, thought they had to look to England more than France for this. He passed round a number of colour screens, and an instrument designed by M. Léon Vidal for testing the colour sensitiveness of plates, and which he was now making. On account of the bad quality and scarcity of the water supplied in Paris, he had cast about for some means whereby perfect washing of prints could be ensured with a limited quantity. He constructed a reservoir, in which were placed, at about three-quarters of the height up, a number of light wooden frames, one over the other, and which were strung across and across with twine, so as to form a kind of sieve. The prints were placed on these sieves face upwards, and the tank filled with water in a slow stream, the surplus being continually syphoned off. He found the prints perfectly washed if left all night, and yet only about four pails of water had been used.

The Hon. Secretary exhibited an album of photographs taken for the arbitrators in the Behring Sea seal controversy, showing the habits and life of these animals in their native state.

Nominations of officers for the ensuing session were made, and a number of suggested alterations of the rules read by Mr. Rapson.

PHOTOGRAPHIC CLUB.

June 17,—Mr. Charles Wallis in the chair.

The Chairman welcomed Professor Stebbing, a member of the Club residing in Paris.

The Hon. Secretary passed round copies of the *Kodak News* and the programme of the Leeds Convention.

Mr. Tottem, referring to some printing-out paper with peculiar markings upon it, which he had shown at a previous meeting, said he had found that these marks were due to the paste used on the label.

Several members expressed their doubts as to whether this was a final settlement of the question.

Professor Stebbing showed Léon Vidal's apparatus for ascertaining the rapidity and colour-sensitiveness of plates. The instrument is a modification of Warnerke's sensitometer. It consists of a series of coloured screens through which the light from a candle is filtered upon the plate to be tested, the resulting impression indicating to which colours the plate is most seasitive. Professor Stebbing said that the instrument is largely used in France, and added, in reply to a question, that the tendency there is for workers to colour-sensitise their own plates. The Professor also showed a series of tinted discs (*Ecrans colores*) of suitable colours for attaching to diaphragms of lenses for isochromatic work.

Mr. Bedding asked if the colours were tested spectroscopically, and an affirmative reply was given.

Mr. Welford then opened a discussion upon the subject of

Art and Science as Educational Factors in the Advancement and Progress of Photography.

He said that this was really a question of art *versus* technique. The particular meaning of the word educational must also be allowed for. He should espouse the art side. Artistic requirements, he said, had improved our processes, our apparatus, and our work, and instanced improved printing methods. Photographs must be judged pictorially—in fact, the public insist upon having art in their pictures, and it is the man whose pictures contain the most art who gets most recognition at Exhibitions.

Mr. Mackie pointed out that Mr. Child Bayley's paper, to which this effort of Mr. Welford's seemed to be a reply, was not a protest against art in photography, but against articles on art in photography.

Mr. Bridge differed from the author of the paper so far as the statement that art had produced improvements in photographic methods. He instanced the commercial gelatine printing-out paper, which was a device for obtaining a passable print from a poor negative. He had no sympathy with the statement that all the art was put into a picture when the exposure was made, or before. He did not find that men who got their living by photography developed their plates a dozen in a dish. The average results would not justify such a course.

Mr. Fry said that art was an appeal to the emotions. He did not think the methods of the worker should be inquired into, or, indeed, had any connexion with the pleasurable sensation caused by looking at a good picture. Every picture must stand upon its own merits, and would appeal to different persons in a different manner. He would give a man who developed a dozen pictures at one time in a dish any credit he thought he was entitled to if one of them turned out a good one. There was such a thing as constructive art in photography, and it sometimes took place long after the exposure had been made. He instanced some of Mr. Robinson's composition pictures, in which several negatives were made to form one complete picture. The picture itself was the thing to be considered, and not the method by which the end was obtained.

Mr. Gotz said that the art side of the question could not by any means be said to stop at the construction of the picture. The painter had first of all to conceive his picture, and then to carry it out. He could no more see that in photography art ceased when the exposure was made than it did in the instance he had given, and which he considered a parallel case. He regarded photography as art based upon science.

Mr. Stretton thought that, as practised by the majority, photography had neither art nor science in it. It had this use, however, that the Philistine could now make a picture record of the places and things he saw instead of maintaining his former barbarous habit of chipping off pieces as relics.

Mr. Bedding said that a portrait photographer, who had to make a pleasing picture for the public, would fare but badly unless he could infuse some artistic feeling into his efforts. On the other hand, the advances in material and in optics, and, in fact, in all branches of photography, had been the result of scientific investigation and improved technical knowledge. The artist and the man of science depend upon one another in photography, and neither would succeed without the other at the back of him.

Mr. Welford, in his reply, said that he could only take Mr. Child Bayley's paper as it stood. He thought it ridiculed the artistic aspiration from beginning to end, and ridicule must always tend to depreciate. He admitted that his paper was a reply to Mr. Bayley's. After dealing with the various speakers briefly, Mr. Welford concluded by maintaining his original position.

MANCHESTER PHOTOGRAPHIC SOCIETY.

This Society made, on the 13th inst., a diversion from the usual monthly meeting, when twenty-four members and friends travelled by saloon car to Delamere, in the heart of Cheshire. After an agreeable walk of two miles, Flax Mere was reached, and soon cameras were at work along its rush lined shores. The route now lay through the midst of the Forest of Delamere, the dense foliage of the trees making a refreshing shade from the almost tropical heat of the sun. Mouldsworth was reached for tea, which, after the long walk, was amply done justice to.

After tea the ordinary meeting was held, Mr. F. W. Burt in the chair.

Mr. A. B. Mitchell was elected a member.

The Hon. Secretary (Mr. A. E. Casson) mentioned that arrangements had been satisfactorily concluded with the Directors of the Manchester Chamber of Commerce, which is to be the future home of the Society.

After a group had been taken, the party dispersed to ramble in the fields, and some to expose on the fine sunset. Assembling at the station, the party reached Manchester about 9.30, after a most enjoyable picnic meeting.

Croydon Camera Club.—June 17, the President (Mr. Hector Maclean) in the chair.

Pictorial Gems with a Hand Camera.

The above subject was ably dealt with by Mr. W. Thomas, who—so the President of the Club informed members—was not only distinguished for the high pictorial qualities of his hand-camera work, but was at the present time notable for his efforts, as Chairman of the Delegates, to infuse fresh vigour in the affiliation of photographic societies. Amongst the points touched upon and the opinions expressed by the lecturer, were that nearly all hand-camera work was rubbish; that the hand camera will or should do just what the brain of the worker wills; that bad technique is never good art; that a good picture may be formed out of anything; that Watkins's actinometer is a great aid to the estimation of exposure; that views should be judged through blue spectacles; that refined smudge and skilful light and shade are better than subject or detail; that chemical fog will cure bad cases of under-exposure, and much more of the like. Mr. Thomas also explained certain rules of composition, which he considered fundamental, illustrating his contentions by a number of clever charcoal sketches. He subsequently handed round and explained a very charming collection of delightful miniatures of sea and landscapes. These were all characterised by a full scale of subtly rendered silvery half-tone, with high lights and deep shadows but sparingly present, in most cases the detail was rather suggested than expressed. In the subsequent discussion the President (Mr. Hector Maclean) took exception to the remark that, "as anything would make a good picture, it is futile to hunt about for attractive subjects." The President considered that, the better the subject and the nobler its features, so much easier is the work of picture-making, so much better and attractive the result. He strongly deprecated in photography, as in painting, the teaching of latter-day innovators, *i.e.*, that the essentials of the highest pictorial art are included in technique. Capable composition and adroit handling are not sufficient, unless there be the statement of a sublime natural truth, or the indications of imagination and culture; a picture may be admirable as a decorative panel, but falls short of the highest level of pictorial expression. Others who took part in the discussion were Messrs. S. H. Wratten, J. T. Sandell, A. Underhill, H. E. Holland, and W. H. Rogers. A cordial vote of thanks accorded by a capital attendance of members concluded the proceedings. The President handed round for comparison recent examples of hand-camera work taken by Frena, pocket Kodak, and Bullseye cameras. He also presented the Club with a copy of his newly published book, *Photography for Artists*. Mr. Underhill presented all present with a well-executed group of between twenty and thirty members taken during the excursion to the Town Hall. Sixteen names were given in of those intending to visit Hatfield House with the President on the 1st prox., and it was announced that the list would be closed on the 24th inst., by which date all who intend going must notify the Hon. Secretary.

Hackney Photographic Society.—June 16.—Mr. E. J. Wall delivered a lecture on

Printing with Silver Paper,

in the course of which he advised amateurs to always buy their paper in cut sizes. Cutting up the sheets involved the risk of waste, and also the chance of spoiling the surface with finger marks. The best way to keep the paper was to place the sensitive surfaces face to face and keep the whole between pieces of strawboard, under a weight. Gelatino and collodio-chloride papers were very sensitive to light, and care should be taken not to expose them to even a small amount, either before or after printing, as, although the effect was not shown at first, it became apparent after toning in the form of degraded high lights. To prepare prints for toning, they must be immersed in running water or a solution of salt, to remove the free silver salts. For gold toning there were two methods, viz., the sulphocyanide bath and the combined bath. Both were good, if made and used properly. For the former, the Ilford Company's formula was correct, thirty grains of sulphocyanide to the sixteen ounces of water. It should be mixed in the following way: Dissolve 30 grains of sulphocyanide in 8 ounces of water; then dissolve 2 grains of gold chloride in another 8 ounces of water, and add it gradually to the sulphocyanide solution—not the latter to the gold, or the resulting mixture would be red and be unfit for use for twenty-four hours. The addition of acetate of soda and other salts to the sulphocyanide bath was of no use, and might well be dispensed with. The addition of salt to the bath made it tone more regularly, but impaired its keeping power. If properly made and used, the sulphocyanide bath could not be beaten. Some seemed to prefer the use of a combined bath; but, as it was always advisable to place the prints in a supplementary fixing bath after removal from the combined bath, the advantages of using the latter were not apparent. Combined baths, to be safe, should never contain lead, alum, or acid salts, otherwise sulphur toning, beautiful but fugacious, would result. A good formula was as follows: Hypo, 4 ounces; soda acetate, 60 grains; gold chloride, 2 grains; water to 16 ounces. The prints must be thoroughly washed first to get rid of the acid. Platinum toning was a very simple matter if the following points were remembered: Always use the preliminary salt bath, have the toning solution acid, and immerse the toned print in a solution of salt and well wash before fixing. Both gold and platinum toning solutions were sensitive to light, so they should be kept in the dark when not in use. The duration of fixing depended to some extent on the strength of the bath; but, if a solution of ten per cent. hypo were used, and this was the best, it should not take longer than a quarter of an hour, and generally not longer than ten minutes, to thoroughly fix. Washing should not be too long, one hour in running water being quite sufficient.

Aintree Photographic Society.—Twenty members and their friends had their third trip of the season on Saturday, June 20, to Llangollen, a splendid afternoon being spent in good weather. The party numbered twenty, and, though there were only half a dozen cameras, plenty of work was found for them in this delightful neighbourhood.

Patent News.

The following applications for Patents were made between June 10 and June 17, 1896:—

Colour Photography.—No. 12,645. "Improvements in and relating to Colour Photography." Complete specification. J. W. McDonough.

Frames.—No. 12,712. "Improvements in Frames for Photographic and other Picture." B. Hodges.

No. 12,772. "An improved Process or Method of and Means for Producing Designs, Written or Printed Matter, Photographs, and the like." T. Sardnal.

Kinetoscope.—No. 12,906. "Improved Apparatus for Taking and Projecting Photographs of Moving Objects." J. B. Medland and W. H. Wood.

Changing Plates.—No. 13,019, "Improvements in the Method of Changing Photographic Plates or Films in Apparatus used for the Exposure of Same." J. W. Jeyes and A. L. Adams.

Vignetter.—No. 13,040. "Salmon's Adjustable Vignetter." A. Salmon.

Kinetoscope.—No. 13,098. "Apparatus for Producing Photographic Impressions in Rapid Succession of Moving Objects and for Projecting the said Impressions for Producing Animated Photographs." P. Gautier.

Correspondence.

☛ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

THE CONVENTION.

To the Editors.

Gentlemen,—Will you kindly allow me to announce to all probable Conventioners that, in addition to the lectures and papers already announced in the official programme of the Convention at Leeds, the Papers Sub-committee of the Council have induced Mr. F. W. Branson, F.I.C., to give a demonstration of *Novelties connected with the Röntgen Rays*. Mr. Herbert Denison, F.R.P.S., has consented to give a demonstration on *Photogravure*, and Mr. E. J. Wall, F.R.P.S., will demonstrate *Colour Printing by the Three-colour Process*.

It is hoped that members in large numbers will attend at the City Art Gallery for the reception by the Mayor of Leeds.' The Right Hon. W. L. Jackson, M.P. (Chairman of the Great Northern Railway), at 7.30 p.m., on Monday, July 13.

The Council also wish to invite members who attended the Shrewsbury Convention to bring with them to Leeds (or send them for selection) good slides from their Shrewsbury negatives for exhibition on the opening night.

May I also state that Messrs. Watkinson & Co., of Leeds, the largest photographic-camera makers in the world, have kindly offered to throw open to all Conventioners their manufactory on certain days, to view the different processes in camera-making; the same firm will also send on all excursions, for use, free of any charge to Conventioners, a commodious dark room for changing plates. R. P. Drage, *Hon. Secretary*.

95, *Blenheim-crescent, London, W.*

LONDON VISITORS TO THE CONVENTION.

To the Editors.

Gentlemen,—It is generally known that reduced fares are this year out of the question, but there might be some advantage for a party travelling together, such as a saloon carriage or at all events reserved compartments. If those intending to go from St. Pancras (Midland) on Monday morning, 13 July, will communicate with me promptly, I will do my best to make the journey to Leeds as comfortable as possible.—I am, yours, &c., Walter D. Welford.

15, *Farringdon-avenue, London, E.C.*

PHOTOGRAPHING AT THE NATIONAL GALLERY.

To the EDITORS.

GENTLEMEN,—Having followed with interest the recent correspondence in your JOURNAL relating to photographing pictures in the National Gallery, I should have liked at the time to have trespassed a little on your space, treating the subject from the professional standpoint. Perhaps it is not now too late.

Shortly, my experience is this. Armed with the necessary permit, I visit the Gallery to see the situation of the picture. If it is not too high up and with a movable glass, all is well; but, if it is a fairly large work with a fixed glass, it breeds trouble and red tape of an antiquated width and length. In this manner I interview Mr. Eastlake or Mr. Ambrose, and say that I could do my work satisfactorily if the picture could be removed from the wall and taken from its frame. In nineteen cases out of twenty this reasonable request is refused. I say reasonable, because of the already existing permit to photograph the picture. I am told that I can instead erect a black screen. In two quite recent cases this meant putting up one twenty-four feet by twelve, blocking up more than half the room, preventing six students from working an entire morning (they were not nice about it), and wishing generally that I had not been born. While the exposure was going on, amiable visitors would stand steadfast in light raiment between the screen and the work. My assistant, not being a polyglot policeman, got tired and struck at the task of "moving on," so I was obliged to swear myself in, in as many languages as I could muster.

If the picture had been removed from the wall, the whole affair would have been finished in an hour, and no one would have been interfered with. It is no question of expense, as clients are willing to pay the necessary costs to obtain the best results.

What makes me kick so much at this nonsense is that, while I am struggling and getting hot, the Gallery attendants are removing large pictures from the walls at the rate of about one per hour, to be photographed by a Continental firm, who, besides having this that is denied an English firm, have also, and have had for nearly two years, more than two-thirds of the largest room in the Gallery walled off for their *sole use* as a photographic studio. Please, sir, do not think me a man with a grievance. My only regret is that public servants, like the National Gallery Trustees and officials, have such an un-English sense of equity and fair play.—I am, yours, &c., GEORGE P. NEWMAN.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

William Arthur Skill, 9, Magpies-square, Lincoln.—*Two photographs of subsidence of the River Witham embankment, city of Lincoln, Nos.* 1 *and* 2.

William John Bishop, King's College Hospital.—*Photograph of men picking stone underground, taken by magnesium light. Photograph of man sawing stone underground, taken by magnesium light. Photograph of men at work with underground crane, taken by magnesium light.*

W. P. D.; PAPER; W. A. T. Received too late; in our next.

GEO. BANKART.—Thanks; we have not the address at hand, but have elsewhere utilised the information, which will, no doubt, thus reach the gentleman named.

CRYSTAL PALACE.—AMATEUR. Photographing in the Palace and grounds is not allowed, as the sole right of doing so is disposed of to Messrs. Negretti & Zambra.

COPYRIGHT.—C. R. J. If there is no copyright in the portrait, as there would not be if you took it in the ordinary course of business, you are not entitled ao stamp the mounts "copyright." It would be a misrepresentation.

BAD LIGHTING.—T. H. W. The flatness in the portraits is due to the lack of shadow. This is folly accounted for if there are only white calico blinds to stop out the sun from the south side while the sitter is supposed to be illumined from the north side. Put dark blinds—say, dark green or black—on the south side, and that will get over the trouble.

EMBOSSING.—T. SYMMONDS. Send us an example to see. Embossed prints may be produced without any costly appliances, but we do not quite understand from your letter the kind of embossing you mean.

MATT OPAL GLASS.—W. TAIT complains that the ordinary pot opal glass is of too coarse a surface for the purpose he requires it, and asks how to get it finer.—We have little doubt that any glass merchant who makes a speciality of this material will supply it with a finer grain. If not, he will have to grind it himself, with fine washed emery, in the way he proposes.

THE R. P. S. EXHIBITION.—H. A. AYLWARD says: "I have a photograph I should like to exhibit at the Royal Photographic Society. Can I do so without being a member? Would you kindly give me particulars through the JOURNAL?"—In reply: You can exhibit without being a member. Full particulars relating to the Exhibition are printed in the JOURNAL of June 5.

ENGRAVED BLOCKS FOR MOUNTS.—P. DOLAN. If you have had brass blocks specially cut for printing the mounts, we consider the price charged for them reasonable. From the tone of your note, we imagine that you did not place the order for the mounts with those who make a speciality of photographic mounts, but an ordinary printer. If that is so, the cost is fully accounted for.

STAINS ON NAILS.—J. P. U.—The stains are difficult of removal from the nails—if not impossible—if they are so deeply seated as yours would seem to be. Those from the flesh can generally be got rid of by treatment with a strong solution of bleaching powder, followed by pumice stone. The bleaching solution will also help with the nails. Why not avoid the stains altogether by more careful manipulation, or by the use of indiarubber finger stalls?

RETAINING SPECIMENS.—OPERATOR. As you have written twice for the return of the specimens, and got no answer, we should advise you, if you do not receive them by the time you see this, to write to the Superintendent of the district in which the advertisers reside. We have had no complaints of the people before; but, if the facts be as said by your friends, they are liable to prosecution for fraud. If by this time you have not got your pictures back, put your case, and the statements of the others, before the Police Superintendent.

COPYING ENGRAVINGS.—PORTRAIT PHOTO writes: "I have had three very old engravings sent me to copy, the paper of which is very yellow—India paper. I have made several negatives, but cannot get sufficient contrast between the yellow paper and the black ink. I use the ordinary plates, not the rapid. Can you give me a tip?"—Either get plates orthochromatised with eosine, or treat some ordinary ones according to the formulæ given in the ALMANAC. Greater contrast would be obtained by, instead of using "ordinary" plates, employing those specially for photo-mechanical work, if orthochromatic ones are not used.

STARCH PASTE.—S. WATSON writes: "We have to mount from 100 to 150 photographs every day, and we find that the starch goes watery after a couple of days, and gets mouldy, and won't stick, a lot always has to be thrown away, which is waste. Is there anything we can add to prevent it going bad?"—Antiseptics may be added, which will prevent the mould; but anything of the kind is not to be recommended while starch is so cheap and its paste so easily made. We should advise our correspondent to make up the paste daily (sufficient for the day's use), and throw away what is left over. Decomposed mountants are a fruitful source of fading photographs.

GOLD SOLUTION.—W. BOURNE writes: "I have a large bottle of solution of chloride of gold, which has been in the place for several years. I do not know how much gold it contains, but I believe it originally came from an electro-gilder's. When I have tried it for toning, I can do nothing with it. Will it be best to send it as it is to a refiner's to get out the gold, or throw that down myself and send the residue only? If the latter, how?"—Yes. Add to the gold solution a filtered solution of protosulphate of iron, acidified with sulphuric acid, until no further precipitate is produced, wash in several changes of water and dry. The result is practically pure gold, and for which you ought to receive something over 4*l.* per ounce.

STUDIO, DESIGN FOR.—SIDE LIGHT. The proportions of the proposed studio are very good, but we are not at all taken with the lighting of it. There should be much more side light, and corresponding in position with that in the roof. The studio would also be improved by being a foot or so higher at the ridge, and six inches or a foot lower at the eaves. This will give more slope to the roof, which will then the better be made watertight, and have less risk of breakage in case of heavy hailstorms. If the sketches are approximately to scale, the lighting will be, practically, all top light. We should recommend that the side light be continued down to, say, three feet six inches or four feet of the floor. Messrs. Marion & Co. have a small work on the subject.

USE OF ROYAL ARMS.—LOYAL writes as follows: "I was greatly surprised to find, in your current issue, that having supplied royalty with portraits did not permit the use of the royal arms, and must thank you for warning given. Kindly let me know, through your valuable paper, does having supplied a member of the English royal family with a photograph (which was accepted), and receiving a letter of thanks in her name, allow me to use the words 'patronised by royalty,' or 'under royal patronage,' without the royal arms?"—Under these circumstances our correspondent is certainly not entitled to use the royal arms. We scarcely think him right using the term "patronised by royalty," inasmuch as the work was not, apparently, executed to the order of royalty. It was simply accepted. However, we do not see any *illegality* in the use of "patronised by royalty," if the royal arms be omitted.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1887. Vol. XLIII.—JULY 3, 1896.

Contents.

EX CATHEDRÂ.

Messrs. Wellington & Ward are placing on the market a specially prepared bromide paper for negative work. The half-plate size will be sold at 1*s.* 6*d.* per dozen. We have had submitted to us a number of negatives made on the paper, and their comparative freedom from granularity is a point that must tell in its favour. Mr. Wellington also demonstrated to us how, by giving the back of the paper a very brief exposure to light before development—say a second, to the dark-room lamp—the granularity of the paper is practically inappreciable when the image is developed.

In our article of last week on *Slow and Fast Plates for Hand-camera Work*, we remarked that, if a magazine hand camera could be arranged to carry two different kinds of plates, so that either could be exposed at will, it would often prove an acquisition. Mr. Frank Miall, of 13, Shelgate-road, Clapham Junction, draws our attention to the fact that the Focussing Facile hand camera fulfils these requirements. Several rapidities of plates can be carried in it at one time, and any of these can be brought opposite the lens for exposure easily and without complication.

Answering a correspondent last week on the subject of coarse-surfaced matt-opal glass, we expressed the opinion that glass merchants would supply it with a finer grain than that which it ordinarily has. Messrs. Moores, De Saulles & Co., of Wordsley, near Stourbridge, send us a sample of extremely fine-ground matt-opal glass, which we think quite fills our correspondent's requirements. Others besides him may be interested in knowing that Messrs. Moores are prepared to meet a demand for fine-ground opal glass.

* * *

Messrs. Wells & Co., of Avenue-road, New Southgate, have sent us some specimens of their work in postage-stamp portraiture, and they remark that they believe they were among the first to supply this kind of production to the profession in this country. The little prints are admirably done, and they are cheap.

* * *

A "photographer of twenty-five years' experience" draws our attention to the fact that the Salvation Army are entering into rather sharp competition with professional photographers. He says: "I would very much like your ideas about the enclosed. Hasn't this sort of thing a very baneful effect upon photographers, and been the cause of such bad prices prevailing? It seems very much on a par with the pound of tea with a cream jug thrown in. I am much surprised at this emanating from the Salvation Army of all places in the world. In rescuing the submerged, are they not submerging some of the rescued? Allow me to ask how many customers will they expect at this sale? They say, *Come in thousands*. How are they going to do these thousands?"

* * *

Two circulars are enclosed with our correspondent's letter, from which it appears that a great trade sale was held last week at the Army's trade headquarters, 98-102, Clerkenwell-road, and among the inducements to seekers after bargains was the statement that every purchaser would be presented with a free cabinet photograph of himself. An advertisement in the *War Cry* alleged that the meetings were crowded, and that the photographer's hair was turning grey. We are at one with our correspondent's criticisms; but it is well recognised that the Army is largely, if not almost entirely, a trading concern, and rather prone to "cutting" and underselling in various branches of industry, so that there is no cause for surprise

that photography has been added to the list of trades that have had reason to protest against the business methods of "General" Booth's organization.

* * *

WRITING from 38, Great Queen-street, W.C., Messrs. Wratten & Wainwright issued, last week, the following notice of removal: "In consequence of the expiration of the lease of our warehouses and offices as above, we propose to discontinue, as early as practicable, the retail of photographic apparatus and sundries, and to confine ourselves henceforth solely to the manufacture of the 'London' dry plates at our factory at Croydon." Messrs. Wratten's sole address is now Croydon, Surrey.

* * *

THE Council of the Society of Arts have awarded a silver medal to Mr. A. A. Campbell Swinton for his paper on *Röntgen's Photography of the Invisible*. Mr. Swinton's paper appears in THE BRITISH JOURNAL OF PHOTOGRAPHY for March 13, 20, and April 3 last.

* * *

A NUMBER of prints made from negatives taken by means of the X rays have been shown to us by Mr. W. I. Chadwick, of 2, St. Mary's-street, Manchester, who was one of the earliest in the field of the New Photography. Mr. Chadwick's results are certainly the finest we have seen, being well exposed and sharply defined throughout. Many of his studies of hands, arms, legs, and feet are interesting from a surgical point of view, besides appealing to us as excellent examples of X ray work. One of the greatest curiosities shown to us was the picture of a hand with a double thumb, with which, we are assured, the owner could write or pick up a pin. Mr. Chadwick's results are all on large plates; thus the hand and the arm, the leg and the foot included on one plate, are invariably shown. These large pictures have, we believe, the preference with many medical men and patients.

A POINT OF COPYRIGHT.

THE case, on appeal, reported in our issue last week, is an important one to photographers, inasmuch as it reverses the judgment of the Sheffield County Court Judge, who decided that, as the defendants had permission to reproduce a photograph in their paper, they were entitled to issue it as a supplement, and also sell it separately from the paper. The result of this appeal again makes it clear that, when permission is given for one definite purpose, it does not extend to any other. Although the law is now clear on this subject, photographers should, in granting a right of reproduction, always make a distinct stipulation to that effect, as per the forms issued by the Photographic Copyright Union, as then there can be no possible misunderstanding in the matter, and legal expenses may be avoided.

There is one point that should always be kept in view when giving licence to reproduce a work, namely, the effect that the reproduction may have on the sale of the photographs. In the case referred to the supplement was a separate picture, and, of course, could be mounted or framed, and thus take the place of the photograph. The same, of course, applies to the large supplements issued with the Christmas and summer numbers of the illustrated weeklies. Some of these are now printed so well, and in such close imitation of photogravures, both in colour and size, that they, when framed and glazed, might well be mistaken for them by a certain portion of the public. This, one can well imagine, must injure the sale of the work, if afterwards published, as an expensive reproduction.

A friend of ours tells us that he recently saw in a shop window a number of small reproductions, framed and glazed, of works now being exhibited in the Royal Academy, the price being about a couple of shillings each, though the frames were only worth a few pence. The prints were recognised as being taken out of the annuals, published yearly, at the opening of the Royal Academy. Of course, the artists or the owners of the copyrights had not given permission for the reproductions to be used in this way, but there is no law, so far as we can see, to prevent them being so used, as any one purchasing the work can do what he likes with the pictures in it. As the prints in some of these annuals are now so good, utilising them in the way mentioned must necessarily militate against the sale of the small photographic reproductions of the same works when issued.

Scientific Kite-flying.—The kite promises to be of great use in scientific observations, from its portability and the readiness with which it can be used for observations from a considerable height. It has been used with a small camera affixed, though the most recent kite work has been devoted to meteorological recording. In the latest ascents, an altitude of almost a mile has been attained. These kites, as explained by Mr. R. de C. Ward, of Harvard University, are not made of the usual form, but box-shaped, with ends open and sides covered partly with silk or cloth. It is stated that a very fine piano wire is used instead of twine. They make splendid flying instruments.

Weather-prognosticating.—Nothing is more unsatisfactory in connexion with photographic tours than a thunder shower; but, according to Mr. B. Woodd Smith, writing in *Nature*, there is one sky sign which, when present, infallibly foretells thunder within twenty-four hours. "It consists in the formation of *parallel streaks* of cloud, seldom more than three or four in number, definite in form, and limited in extent and duration, appearing either as white streaks on the blue, or more rarely as darker streaks against nimbus or cumulo-nimbus. I have rarely seen these parallel bars, as I have come to call them, without their being followed by thunder within twenty-four hours." It appears that the first description of this prognostic appeared in *Nature* in 1888.

The Eclipse Observation Arrangements.—A slight hitch, which, however, it is not supposed will interfere with the projected arrangements, has happened in connexion with the vessel, the *Volage*, carrying Mr. Norman Lockyer and his equipment. She has been detached from the training squadron, and is now undergoing repairs at Portsmouth. All the ships of this squadron are to proceed to the neighbourhood of the Valanger Fiord, to observe the eclipse. Novaya Zembla will be the station for the Russian observers, and, as Sir George Baden-Powell has offered his yacht for the purpose, it is probable that English observers will also proceed there. The Harvard College expedition goes to Japan, their special object being observations by a large prismatic camera.

Dr. Hugo Schroeder's Corrector.—Dr. Schroeder describes in *Photographische Mittheilungen* the use that can be made of a compound lens with external plane and parallel surfaces, the component lenses joining internally at surfaces of any suitable curvature. The simplest form may be produced by the aid of an ordinary achromatic plano-convex lens ground to a plane on the curved surface. It would then have almost the same spherical and chromatic aberra-

tions as the removed plano-convex portion, but with opposite signs. The character of the lens may be reversed by substituting crown for flint, and *vice versâ*. Such a lens, placed in the cone of rays from an objective, would indicate the effect producible by altering the curves of the latter. By its aid an ordinary telescope (achromatic, of course) can be utilised for photographic purposes, but the field of view will be very restricted unless the corrector be made of as large a diameter as the objective itself.

Cycles as Studio Accessories.—It is, or used to be, common enough for photographers, in some parts, to be provided with costumes of the country, to take visitors' portraits in. For example, we have a portrait of the late Mr. Baden Pritchard, in Arab costume, taken on the occasion of his trip to the great Sahara, a stock dress supplied by the photographer. The late Mr. Adam Salomon also had a stock of "property" dresses, mostly of velvet, for the use of sitters. Cycles now, it would seem, have become a photographic "property," for we noticed in the window of a well-known photographic firm at the West-end, the other day, the following announcement: "To lady cyclists. Ladies photographed on bicycles. Machines kept in the studio." This is certainly a novelty, and, we have little doubt, attracts some additional business. It certainly saves ladies bringing their cycles to the studio. It may also induce some to be taken on a machine who have never mounted one before, just for "the fun of the thing," or to see how they would look on a bicycle. As the cycle is such a *furore* amongst ladies just now, we shall not be surprised to see other houses following the example set, and introduce cycles as accessories in the studio.

A Curious Obliteration of the Photographic Image.—At the meeting of the Photographic Club last week a curious instance of the disappearance of a collodion picture was shown. It was, or had been, a micro-photograph of the Hon. Secretary; but in the course of a few days, although protected by a cover glass, the image had entirely disappeared. It was explained that the minute picture was developed, fixed with cyanide of potassium, and washed in the ordinary way, the latter operation being more carefully performed than usual. The thing seemed very mysterious at first, but it was elicited that, instead of the cover glass being cemented on with Canada balsam, a few drops of Sœhnee photographic varnish was used. This varnish, it was explained by some of the old collodion workers present, is made with very strong spirit, and some kinds of pyroxyline are soluble in very strong alcohol, as turned out to be the case with that used for the collodion in this instance. When the thin cover glass was pressed on, a certain portion of the spirit was imprisoned and could not escape. It then had a prolonged solvent action on the collodion, so that in the end the particles of silver which had formed the image became diffused in the film, and so it became effaced.

A Scenic Artists' Trades Union.—A meeting of scenic artists was recently held in the neighbourhood of Covent Garden to protest against the "cutting prices" in the profession. After discussing the subject for some time, it was resolved to form a union for self-protection. A correspondent, in calling our attention to this matter, says, if scene-painters and those engaged in stage effects can form a trades union, why cannot photographers' assistants? The query is certainly a pertinent one, though the two cases are not quite parallel. To become a scene-painter or a scenic artist requires considerable training and art knowledge very different from that required now by photographic assistants, such as those whose grievances have recently been so ventilated in these columns. Moreover, we fear there is not sufficient unity amongst the latter; that has always been the case with photographers, both employers and *employés*. Some time ago there was a meeting of "process workers" to fix a minimum price for blocks, and, although the principal towns agreed on one, it has not influenced the "cutter" of the "garret-master" type; he still "cuts" as low as ever, if not lower. It is a pity there is not more unity amongst photographers in the different branches than there is.

Has Amateur Photography Reached its Zenith?—When a thing has reached its height, it is generally said to subside. Is that the case with amateur photography? This question occurs to us from the fact that apparatus-makers, dealers in materials, and others who cater more especially for amateurs, complain that trade is not nearly so good this season as it has usually been for several years past. This complaint is not confined to the metropolis, but extends to the provinces as well. What is the reason? That given by one and all that we have spoken to on the subject has been the same—the craze for cycling. People, it is said, now prefer to lay out their spare cash on the latest thing in cycles who used to spend it in photography. Cycling has become a fashionable hobby amongst both sexes, and promises to stay. Many entered the ranks of amateur photography, not for the love of the art, but simply because it was fashionable. Such people, however, must not be classed as the genuine amateur photographers, for they are ready to change their hobby for the next fashionable craze. They were, however, good customers to apparatus-manufacturers, as well as plate-makers, and they are now missed. The cycle and camera used to go hand in hand, but now the latest phase of cycling, with both sexes, seems to be "scorching" along the road on the lightest and latest machine, regardless of the picturesque.

Röntgen Sciographs of Bullets in the Head.—At a recent meeting of the Paris Academy, MM. E. Brissand and Londe exhibited photographs, by the Röntgen rays, of a bullet lodged in the brain. Last Friday, Li Hung Chang visited the Charlottenburg Polytechnic, and, after being shown a number of experiments with the New Light, consented to an attempt being made to discover, by means of the rays, the position of the bullet fired at his head by the assassin at Shimonoseki last year. The image of the head which was obtained shows clearly the track of the bullet in the left cheek, and the bullet itself lodged in the tissues slightly below.

Important Suggestions for Improving the Vacuum Tubes for Röntgen-ray Work.—Mr. T. C. Porter, of Eton College, in a lengthy communication to *Nature*, indicates a series of improvements in the use of the focus tubes which promise to improve the rapidity and sharpness obtainable with the ordinary tube. The following extracts from his letter contain the practical parts of his article.

"After examining the fluorescent and photographic action of the rays (X_2) emitted on strongly *heating* a 'focus tube,' and finding them different to the rays which have been hitherto noticed (X_1), in that the relative transparency of flesh, bone, aluminium, and glass differs for the two kinds of rays, it seemed desirable to try the effect of cooling the tube. Solid carbon dioxide and ether, and then solid carbon dioxide alone, were employed, with the result that in both cases the fluorescence of screen and tube very rapidly died out, and the current apparently failed to pass through the latter; as the tube gradually grew warm again, the fluorescence in it returned, not gradually, but very suddenly, at a temperature not very far below that of the room, the glass lighting up brilliantly, and the shadows of the bones showing on the screen with increasing distinctness, the emission of X_1 rays reaching a maximum at about 12° C. (a rough guess). On further heating, X_2 rays begin to be evolved, judging from the increasing opacity of the flesh, whilst at the same time the fluorescence excited on the screen grows rather brighter, until the state recorded in my paper of June 4 is reached. As the condition for the maximum of X_1 rays probably varies to a certain extent with the different forms of tube, and even different specimens of the same kind of tube, with the degree of exhaustion, &c., it seems to follow from these experiments that, in some cases, warming the tube slightly might be useful in photographing the bones, whilst in others moderate cooling would be better; and from the accounts of various operators such would seem to be the case, though, as will be seen in the light of subsequent experiments, the particular method of heating or cooling is an important factor in the result. Solid carbon dioxide seems very opaque to the rays when its low density is considered, but the effect may have been partly due to the frost condensed upon it from the air.

"During some experiments on the tube with an 18" Wimshurst

machine, I noticed that the X_1 rays, *i.e.*, those showing the bones best, seemed to be emitted or not according as a brush discharge occurred on the wire leading to the anode of the tube, close to the tube, or not: and that the 'electric wind,' which blows from the tube as from all charged bodies, seemed also to vary in intensity with the X_1 ray flashes, the X_1 rays being most copiously emitted apparently at the moment when the brush discharge ceased or the wind moderated. I soon found that by making a small brush on the wire near the anode, or drawing one with the finger from various parts of the tube (but not from all), best from the circular section of the tube in a plane with the edge of the kathode mirror, or in the very immediate neighbourhood of this line, the discharge producing the X_1 rays could be induced at will in a tube which was not otherwise giving them, or, at any rate, only giving them very feebly. Thinking, therefore, that the production of the X_1 rays must be in some way connected with intermittent leakage of the charge which resides on the outside of the tube (a continuous drain stops fluorescence and the emission of any rays capable of exciting my fluorescent screen altogether), I tried various ways of drawing off this charge intermittently, with several curious results; but the plan I find to work best is to place a ring of plain copper wire round the tube in the plane of the kathode mirror's edge, not touching the glass, but very near it, and then to cause a very rapid but intermittent discharge by bringing a wire connected to earth within a *very small* distance of some part of this ring; so far I cannot discover any particularly favourable position. The sparks between this ring and the earth wire are very small, but the effect on the fluorescent screen exceedingly striking.

"What is still more interesting is that not only is the discharge of X rays made much more regular (when the adjustment of the ring and wire is carefully made), but *the X rays can thus be induced in a tube with a far weaker current;* the weakest current capable of inducing sparks between the ring and conductor seems capable of giving the X rays, though they are more copiously emitted with a stronger current.* And not only so, but the tubes I have experimented with seem to show as yet no symptoms of growing fatigued. I have caused a brilliant emission of the X rays from a tube which was before 'fatigued,' at least, my coil seemed too weak to excite it, and the emission of X_1 rays has been sustained for over two hours with but a few short intervals without showing any signs of diminution, judging by the screen effects; but, on the withdrawal of the ring and wire, it at once failed to give any. This seems an important result, for it must greatly shorteu the exposure and fatigue necessary for the photography of thick objects, and also greatly save the expense of the operations.

"In one experiment I placed a ring round the glass in the plane of the concave mirror of a Crookes' tube, showing the 'independence' of the positive pole, from which I could not get any X rays, and found, on extracting a series of small sparks from it with a wire leading to earth, a very decided increase in the still general fluorescence of the tube, but it gave no rays. Incidentally it was noticed that, when a wire brush connected to earth was pressed lightly against the glass over the dark spot opposite the kathode, in every place touched by the wire, a most brilliant green fluorescence was excited, which faded away very quickly when the brush was withdrawn. It is therefore certain that much may yet be done to increase the efficiency of the tubes used for the production of X rays by a further study of the action of neighbouring conductors upon them.

"*Addendum*, June 13.—After trying various forms of conductor, coating different parts of the X ray tube with Dutch gold and aluminium leaves, I find the following a most effective plan, and feel no hesitation in recommending it. First coat the external part of the tube between the kathode wire loop and the aforemeutioned plane of the edge of the kathode mirror with any conducting metallic leaf, being careful that none of it projects beyond the trace of this plane on the glass of the tube. Next coil a stout piece of copper wire into a circular loop with a stem, and place it so that, whilst the loop is in the plane of the edge of the kathode mirror, it does not touch either the glass of the tube or the metallic coating. I find an interval of about the one-twentieth of an inch answers excellently. And, lastly, instead of using a wire to earth, bring the stem of the looped wire, or, better still, a more pliable piece of wire connected with the loop stem, within a very short distance of the part of kathode wire from the coil close to the tube. The adjustment is easily made in practice, and the emission of X_1 rays which follows will, I think, be found satisfactory, to say the least, especially when it is remembered that, without the looped wire, the tube may be giving no X rays at all."

* I have succeeded in eliciting feeble X rays from a Newton's focus tube with a small coil giving only one-third of an inch spark, using the ring and earthed wire or finger.

DIGRESSIONS.

VII.—Some Heresies about Portraiture.

In every work of art there is something more required than fidelity to facts, whether the work is painting, literature, music, photography, or any other creative art. In speaking of novel-writing Sir Walter Scott, who was a genuine art workman, expresses this fact very clearly. He says: "Though an unconnected course of adventures is what most frequently occurs in nature, yet, the province of the romance writer being artificial, there is more required from him than a mere compliance with the simplicity of reality." It is evident that this opinion obtains even among the writers of history, whose mission, judging superficially, one would think would be facts, but whose first thought, apparently, is the decoration that shall be hung on to the facts, and whose first rule seems to be, "picturesque certainly, true if possible, and if it suits me." All arts are only variations of one, and I don't see why photographic portraiture should be treated as an exception. We don't want the anatomical facts of a man, the hairs of his beard, the freckles of his skin; we want the air, the spirit, the character, the "go" of him. Likeness we must have; but, if we get character, our faithful art will take care of the likeness. There has always been too much insistance on the petty details of a man's face. Who cares for Cromwell's wart? The anecdote tells us something of the mind of the man, the wart itself nothing. It has been a stock exclamation with photographic writers, "What would not the world give for an untouched portrait of Shakespeare?" Why should we desire it? If I may judge from my own feelings, we don't want anything of the kind. We have been brought up with the existing portraits, and we no more want to have our fixed ideas of him altered than we want a wicked American to prove that his divine plays were written by Lord Bacon.

For my part the first portrait of Shakespeare I met with—some time in the last half century—was a copy of the *Droeshout* in the first folio, next the Stratford-on-Avon bust, and I don't think my life felt quite fulfilled until I had acquired a copy of the original plate of the engraved portrait and a cast of the bust. They agree sufficiently well as a likeness to show they are not copies, and they represent the man I have all my life believed to be the poet, and I don't want to change him. I have to put a surprising restraint on myself to prevent this becoming a stupendous digression, for I should like to say a lot about the collection of those various editions which have nothing to do with photographic portraiture.

But, if we don't get the facts, we want the effect. The greatest portrait painter we ever had, Sir Joshua Reynolds, never minutely copied the features, but he gave us the man at his best, and he usually convinces us, who never saw the original, that it is a "wonderful likeness;" witness the portrait of *Lord Heathfield* in the National Gallery—surely nobody would venture to say that that was not like. This is a very characteristic example of Sir Joshua's method of portraiture. He seldom represents his figures in fixed attitudes, but sets them "in the midst of active life as if simply interrupted by the artist's arrival."

In one of his lectures Constable spoke of this noble work, and showed how much meaning, what a history could be put into a portrait. He described it as "almost a history of the defence of Gibraltar. The distance, with a glimpse of the opposite coast, expresses the locality, and the cannon pointing downwards, the height of the rock on which the hero stands, with the chain of the massive key of the fortress twice passed round his hand, as to secure it in his grasp. He seems to say 'I have you, and will keep you!'" This, with the determined expression of the grand old man, makes a portrait picture worthy of the photographer's earnest consideration—if not imitation. It is not every man who is worthy of having his history painted in hia portrait, neither are such elaborations of thought and manipulation of accessories adapted to our art.

Every professional portrait photographer must have noticed what has probably been to him an experience difficult to explain. We will suppose he has sent home three or four proofs for selection—two or three of them which he thought the best, retouched, mounted, and finished. He may have set his mind on one to be specially proud of, yet in the resulting order the prints which he thought best were rejected, and the number required ordered from the one proof that

was included on the off chance that a copy or two might be ordered. This is not a rare instance but happens continually, and the lesson to be deduced from it is, that there are some natural qualities in a portrait which will excuse defects and supersede a good deal of the artfulness which is not art.

It is not possible to consider your work too seriously, but it is very possible to make too much parade of being careful, or, indeed, of really taking too much care. Care is said, by the best authorities, to have had the good fortune to kill a cat, and too much show of it in the operator certainly takes it out of a sitter. The same thing has happened in painting. It is related in Redgreave's *Century of English Painters* that "Lawrence was fettered latterly by his very fastidiousness and desire of surface finish, as well as by his endeavour to give the most polished aspect of his sitter." Reynolds and Gainsborough, the latter more especially, struck off some of their best portraits at a single sitting.

It seems almost immoral to say a word against hard work, but much mischief is done by over-elaboration. I would, however, rather put it that in portraiture the work is done in the wrong place. Broadly speaking, the work should be done before you come to the camera.

Here I am off on a digression. I noticed with many photographers, landscapists as well as portraitists, that they can only see their picture on the ground glass. They would find it much more convenient if they would learn to see their composition in nature, and refer to the camera only to see that the right amount is included in the field, the head in the right place, and for focussing none of which should require much correcting at the last moment. In the case of a portrait these operations should take as short a time as possible. Anything in the shape of flurry or doubt is distressing to a sitter. It ought not to be necessary to say this, but it has been my observation that photographers sometimes *take too much care*, which often takes the appearance of flurry and doubt. They must try this, and try that; have practical demonstration in the camera of how the face looks in profile, three-quarters, or full, and often feel it difficult to decide, and must have another look, and all the time the sitter is *wasting*. All this should have been settled long before the victim sat down. The clever conjurer never gives you time to find out his tricks. I must admit there is sometimes a little danger the other way. Some old ladies are quite capable of accusing a photographer of not doing enough work for his fee, although his skill has probably secured an almost impossible portrait of a difficult sitter.

Those from whom the artist hides the art seldom take into account the awful amount of talk, and shall I say humbug, that has to be let off before what they think is all that happens begins.

I am sorry to say that many photographers think they know all about portraiture because they can take a photograph. Will it seem much of a paradox if I say portraiture is quite a different business from photography, and that photography is only one of many means of producing a result? All portraitists, whether they use photography, paint, pencil, or marble, should have the same qualifications with their individual technicalities added—the same instinct, the same knowledge of human nature, the same shrewdness of observation, and knowledge of established rules of art, or, in other words, what arrangement of lines and masses will make the best effect.

Here I am off down a new siding. Some years ago, about a dozen I think, a loud but inadequately informed voice denounced rules of art as conventional. Now a shrewd philosopher has noticed that, when once a general statement has been brought into a sort of convenient formula, it is repeated and echoed by persons who have no clear idea of its meaning, and frequently adopt it in circumstances with which it has little connexion, which may account for many eccentricities of fashion. Certain it is that the denunciation of the established rules of art has not only abated, but these convenient conventionaliams are being looked on again with some respect. Although Sir Joshua Reynolds's discourses have been quoted until we almost know them by heart, as they deserved, I may do worse than tell you again what he has said about study, and those who have the folly to begin by presuming on their own sense:—

"I would chiefly recommend that an implicit obedience to the rules of art, as established by the practice of the great masters, should be exacted from young students; that those models which have passed through the approbation of ages should be considered by them as perfect and infallible guides, as subjects for this imitation, not their criticism; for it may be laid down as a maxim that *he who begins by presuming on his own sense has ended his studies as soon as he has commenced them.*"

The photographer who wants an excuse for not doing his possible best will say, "This is very lofty talking, but many sitters would never make pictures, however well treated. This is very true, and I admit that in these hard times they cannot be turned away. Adam Salomon rigidly selected his sitters, but that method is not open to every photographer; but I do ask every photographer to qualify himself for doing much better than he has ever done, in a better manner, and to *charge accordingly!*

H. P. Robinson.

BY THE WAY.

This is the season when we are naturally led—in thought, at least, if not in actuality—into the open air rather than to the meeting room, and when, in fact, photographers are to be found engaged in practical camera work rather than in the discussion of technical points before the societies. Yet what a change has taken place, even in this respect, during the past few years. We do not need to look back very far to find a time when the most ardent devotee of photography, if he happened to feel a longing for the stuffy meeting room of his club or society in preference to the breezy mountain side, would have found it impossible, within the boundaries of the three kingdoms, to gratify his wish during the present and next two months, for I believe I am correct in saying that there was not a single society existing that did not close its doors, so far as evening meetings are concerned, for at least two or three months of the year. But now, whether it be owing to an increased love for the technicalities, a spread of social feeling, or an alteration in the nature of our meetings, I cannot say, scarcely a town of any importance but has at least one meeting a week, even during the dog days, while in some of the great centres, but especially in the metropolis, it would not be difficult to fill in every night in the week with photographic recreation (?).

Then, as if the regular meetings did not suffice to satisfy the craving for science and sociability combined, we have a sort of extra festival in the shape of the Convention, where outdoor work and pleasure are combined with technical meetings and talk, rather, it must be admitted, to the disadvantage of the two latter. I may or may not be present at the Convention, but if I am I shall be strongly tempted to raise, or cause to be raised, the question of meetings generally, not so much from the point of view of their over-frequency or the reverse, nor of the scientific *versus* the sociable, or, as it has been irreverently described, "the beer and tobacco" side of the question, but simply and solely from the point of view of reporting.

I have for a long time personally felt a strong desire to grumble at things generally on Wednesday, Thursday, and Friday mornings, when I open my photographic papers and find so very small a proportion of matter that I do not pass over unread, simply because it is matter that is as old as the hills, and, if it were not, has no earthly interest for me or anybody else beyond the Secretary of some distant village society, or, possibly, some happy individual who, having made his *début* as the reader of a paper carefully compiled from available sources, is pleased to see it and the discussion thereon well "displayed" by his friend the Hon. Secretary. It is an excusable kind of feeling, I know from personal experience, and, though time has done much to soften the pangs of disappointment in my own case, I shall never altogether forget the feelings of pleasurable excitement of hope and, shall I confess it, of disappointed surprise that attended my first "paper," read before a photographic society in the good old days of stiff formality. No matter what the subject was, but it was one that at the time was exercising the public mind considerably, and it had pleased the Hon. Secretary and Committee of my Society to think, or profess to think, that I could throw some light on it, and I undertook to read a paper at the next meeting.

The eventful evening arrived, and so did I, but it was not long ere I recognised that I had done a distinctly unwise thing in inviting some half-dozen non-photographic friends to witness my triumph. Somehow I did not seem to care twopence for the whole Society, President and all, but those half-dozen "laymen," with the scarcely suppressed air of expectant amusement that wreathed their countenances, completely upset me, and I am afraid the performance was not an elocutionary success in any sense, and my outside friends themselves confessed afterwards that even they pitied me. However, when it was over, a feeling of satisfaction came, which was slightly dashed when no mention of my paper, or even of the meeting, was to be found in the local prints. In due course the meeting was reported in the only two journals then existing, and one of them published an abridgment of the paper without any comments, the other ignored it altogether, and from that day to this neither the *Times*, nor any of the papers that occasionally take cognisance of scientific matters of more than ordinary importance has had the slightest reference to the matter.

But that was in the days when the whole of the photographic meetings of the year could have been comfortably squeezed into a week, and not have made so crowded a time as the present, and there would have been some excuse for making "copy" of my unfortunate paper and the discussion thereon, but now I should really not expect it. Then, again, there is another matter to be looked at. Under the Affiliation scheme we may expect papers to be read over and over again, and though, if printed *once*, I scarcely imagine they would be reprinted if read a second or a third time, yet the mere repetition of the fact is irritating and unnecessary.

But this is not so bad as to notice, as I have done no less than *three times* on a single page in the reports of different provincial societies, the announcement that "Mr. De Monstraytor of the Camera Plate Company" had kindly given an interesting address on the conversion of sensitive films into gold and silver, &c. It is all very well, if it pays, to send travelling demonstrators about the country, and undoubtedly, in places cut off, so to say, from the metropolis and civilisation, they fill a valuable and useful position; but there is no need to take up valuable space in the weekly journals to chronicle these important events.

But the difficulty is what to do in the matter. It is a question, I fancy, that hinges more on the common sense of secretaries than anything else, for it is upon them, I assume, that the editor is dependent for his reports of meetings in the great majority of cases, and it is too much to expect that already overburdened individual to spend his time in cutting down and rewriting the reports of the some hundreds of societies' meetings that take place in the course of the year; which is "why I remark" that I think the Convention would provide a good opportunity for ventilating this matter generally.

But there are some directions in which editorial action might be taken and editorial severity, I think, exercised without injustice. Some few months back I remember a discussion taking place over some trivial matter in which a dissatisfied member impugned the correctness of a secretarial report. Of course, in any matter of vital importance, a correction of this kind may, and in all justice should, be made; but, when the thing resolves itself, as it did in this case, into a bit of trade jealousy, the Editor can scarcely be charged with undue interference with the liberty of the subject if he promptly "sits upon" the whole business. More recently we had the spectacle of the purification in public of the soiled linen of another provincial society, in which apparently two factions existed, and, though the internal arrangements of that society may be of the highest interest to its own members, their little quarrels don't greatly interest the outside world.

Precisely the same may be said with regard to the still more recent Cardiff Society discussion; it is scarcely of paramount importance to anybody whether one member "runs" a barber's shop or another plays the flute in a local band, but it is a sorry spectacle to see such personalities introduced into a discussion of any sort, and it scarcely reflects any credit upon the society to which the said members belong, and certainly does not affect the question upon which the discussion started. It seems to me that, in a place like Cardiff, the authorities of the Exhibition did the wisest thing they possibly could in offering the management of the photographic department to the local photographic society, who would certainly seem to be the most likely body to understand the business. As the Society does not profess to be a strictly amateur one, I fail to see where the question of amateur *versus* professional comes in; and, indeed, if it were an amateur Society, it seems to me that, if in their collective capacity they undertake the risk of management of the photographic part of this Exhibition, it would be a pity and a shame if they did not make some profit out of it. So far as I can see, it is really not a question of individual amateurs making a profit, but simply of the Society collectively undertaking a task in the interest of photography generally, and endeavouring to do it without pecuniary loss. Could any one reasonably object to the Royal Photographic Society making their Exhibition a pecuniary success? Yet, I believe, there are one or two *bonâ-fide* amateurs belonging to that Society who do not feel to lose status as such in consequence of the Exhibition.

Some other day I may indulge in a growl on the subject of the "rot" that is talked on the subject of amateurs and professionals—for such it really amounts to; and the introduction of the question in this Cardiff business is a good example. It is generally a certain class of professional who is only too glad to make the "amateur" the excuse for any and everything. DOGBERRY.

PHOTOGRAPHIC WORKERS AT WORK.

VIII.—MESSRS. MARION & CO. AT SOUTHGATE.

THE works at Southgate, at which the papers, plates, and other products of Messrs. Marion have their origin, are situated on the northern edge of that pretty old-fashioned village, as yet unspoilt by the hands of the jerry builder, and are about a mile and a half from Palmer's Green Station, on the Great Northern Railway Company's Enfield branch. On the occasion of our visit we were unable to be conducted by Mr. Alexander Cowan, who, as works manager, has identified himself with the large factory, every room in which bears evidence of his ingenuity and invention, as he was confined to his room by an accident which has resulted in a broken leg, but enjoyed an efficient substitute in his son, Mr. Ashley Cowan.

The factory consists in a great measure of two large buildings, similar in external appearance and placed at right angles to one another, but entirely separate and each complete in itself, with a view to avoid any stoppage which a fire might otherwise occasion. In addition to these two buildings, there is an annexe of considerable size to one of them and a number of smaller structures. Entering the annexe just referred to, we find it contains, in addition to an office, a dark room for experimental work, packing rooms, and one devoted to speed measurement, to which we shall refer later on.

In the first of the main buildings we notice a 3½ horse-power Otto gas engine, which supplies the motive power for that factory, and pass it by to enter the emulsion-making room. Here are to be seen a number of stoneware "coppers," set in pairs in square masses of brickwork. Each copper is surrounded by a metal vessel of similar shape, through which a stream of water can be made to pass, while underneath is a powerful gas burner. The coppers are provided with light-tight lids, through which passes a vertical spindle, carrying stirring arms on its lower end and connected up above to shafting to rotate it. By means of the light-tight lid, the emulsion as soon as it is mixed can be cooked and stirred the while, the room being in full daylight; in fact, this was the case on the occasion of our visit, two of the coppers being then in operation. The lid of each copper is provided with a small hole closed with a plug through which a thermometer can be introduced if desired, the temperature of the emulsion being controlled by the cold water which can be caused to circulate in the outer vessel by turning a tap, a little opening in the outflow pipe being left so that the temperature of the water can be ascertained as it leaves the vessel. Light is obtained by means of lanterns provided with yellow fabric windows, and containing gas jets, while sliding doors to the window frames of the room allow it to be flooded with daylight when it need not be otherwise.

In another room is to be seen the glass-cleaning machinery, through which the glass plates are passed before they go to the coating room. Each plate is laid down upon rollers, which carry it between scrubbing

brushes moving backwards and forwards over both faces of the glass. The plates pass from the brushes up a long trough, during their passage up which they are rinsed by a series of streams of water from pipes which cross the trough every four or five inches. At one end of the glass-cleaning machine stands a girl who feeds the glass plates into it, while they are in like manner taken off at the other end, stood up in racks, and carried to a hot-air chamber which rapidly dries them. They are then stacked up in trays, and taken to the coating room.

Before describing the operation of coating, there are one or two rooms to which we must give attention, as they are those in which the emulsion, after it leaves the "coppers" in which it has been cooked, is washed and filtered. The first of these is devoted to the melting of the emulsion, and for this purpose contains two huge earthenware vats, each capable of containing 120 gallons. These vats, like the smaller ones in the emulsion-making room, are mounted in water baths for melting up the finished emulsion. Leading out of this is the filtering room and emulsion store. The word emulsion is derived from the Latin, and means literally a milk-like substance; and the true force of this derivation was brought home to us as we entered the room in question. Nothing more like a model dairy could well be conceived. Clean, cool, and airy, the floor covered with a lot of light-tight earthenware jars over each of which was a white cloth, the resemblance was striking.

The filtration is effected by means of a large globular earthenware vessel open at both top and bottom. The filtering material, leather or nainsook, being tied over the bottom, the emulsion is poured in above and allowed to run through by its own weight, a little force only being needed at the finish. The filtering vessel is mounted on rails projecting from the wall, so that a number of jars are arranged in a row, and the vessel is merely wheeled along from one to the next as each jar gets filled up. When the jars are full they are covered over with their lids, and a cloth moistened with dilute carbolic acid laid over each to guard against the slightest chance of putrefaction.

Leading out of the room just mentioned is one devoted entirely to the washing of the emulsion. In this the jelly-like mass cut up into thin shreds is placed in revolving cylinders through which a stream of water is kept running. As this room is kept absolutely dark, our knowledge of the process is derived from Mr. Cowan's description, which was corroborated as far as it went by the rolling sound of the cylinders which then contained emulsion.

Having in this way seen both the emulsion and the glass through the various stages of preparation, we went into the coating rooms to see them brought together. These rooms are, of course, lighted only by the feeblest yellow light, and it was some little time before our eyes accustomed themselves to the darkness, and were able to note anything likely to interest the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY. Entrance to the rooms is obtained, not through doors, which would be awkward to pass when laden with a tray of glass plates for the machine, but by means of a winding passage, which effectually cut off all light before the room itself was reached. There are two of these coating rooms and another in process of formation, but a description of one will serve. The passage opens up into one end of a long narrow room, all down one side of which is the coating machine itself. At the end nearest the machine is an *employé*, whose duty it is to keep it supplied with glass plates. These are carried by rollers upon which they are laid, first under a dusting brush, which ensures their top surface being perfectly clean, and then under the opening of a V-shaped trough, which delivers on to the plate a coating of emulsion. The thickness of this coating depends upon the rate at which the emulsion is fed into the trough, the source of supply being a large glass aspirator or bottle with a stopcock at the bottom, from which the emulsion runs in a thin stream into the trough. The plates, touching one another in a long procession, pass under the trough and then onward down a long narrow box-like structure ending in a roller. This roller, the circumference of which travels a little faster than the stream of plates, takes each plate up and passes it on into another long box, the bottom of which is formed of slate slabs. Down these slabs endless cords are continually travelling, and the plates, separated from one another by reason of the increased rate at which the roller and cords travel, glide on down the trough. As they do so, a little jet of water underneath them ensures that their under side is completely wet, in fact they glide on a film of cold water, in consequence of which the emulsion is set by the time the plates reach the far end of the box, where they are at once placed in racks and sent up into the drying room overhead. The coating machine is thus seen to be to all intents and purposes a long, narrow, shallow box, down which the plates are carried, and in so doing are dusted, coated, separated, and then, by means of cold water, set. The top of the box is covered with sheets of glass which protect the plates from dust, while at the same time allow the operations to be seen. One of such machines is capable of coating six or eight gross of whole-plates per hour, the actual number depending to a certain extent on the time of year, since the plates can only be passed through at such a rate as allows of their setting, and this takes place, obviously, quicker in winter than in the warmer months.

So far we have been entirely on the ground floor, the upper floor being devoted to the drying of the plates. This is done in the racks in which they leave the coating machine, which are sent up by a lift and passed, by means of rails, through the drying room, each rack pushing on those in front of it. There is no need to visit the drying room to ascertain the temperature, as a box in one of the rooms down below contains pulleys and cords, by means of which a maximum and minimum registering thermometer from each of the two drying rooms could be brought down for inspection at once, the box containing a book in which the temperature of the drying rooms is regularly entered up.

Messrs. Marion, as is well known, do not confine themselves to the manufacture of plates alone, but make also celluloid films as well as gelatino-chloride and other papers. The process of film coating is almost identical with that of the glass plates. The celluloid in strips not more than a yard long and a little wider than the size of the finished film is laid down upon glass plates coated with a composition which holds the film firmly and quite flat, but allows it to be separated easily by pulling. These glass strips carrying the film in this way are passed through the coating and drying operations, the film is then pulled off its glass support, cut to size and packed, while the glass goes back to have a fresh piece of celluloid laid down upon it for coating.

We now turn our attention to the other of the main buildings. This also is provided with its gas engine, of the same power as the other, but of a later and more compact pattern. This building also contains a number of lathes and other tools required in fitting up and maintaining the factory, and at the time of our visit was being provided with another coating machine and drying room for plate-manufacture.

On the upper floor we found the paper-coating machinery. A lift brings up a roll of paper and deposits it close to the machine, it is fitted in and fed round a series of rollers, coated with emulsion and automatically hung in long festoons up and down the room, provision being made for drying a mile of paper at a time. Paper-coating machinery is very much alike, and the general arrangements we have only recently described. At Southgate, however, there are one or two modifications which interested us. The paper is not passed round a roller through a trough of emulsion, but the latter is fed up against the surface of the paper in a smooth stream. As it travels vertically upwards, the paper picks up as much of the emulsion as it will carry, and the surplus flows back into the receptacle from which it is pumped up again for use. The coating machine possesses also a novel and ingenious arrangement by means of which, when the coating is stopped, the paper is cut off clean, the bottom part held so as not to necessitate threading it through the rollers when it is required again for use, while the loose-coated end has a dummy or apron of fabric attached to it, to carry it round the rollers so that the loose end is not wasted.

In this part of the factory is also a winding-up machine for the paper when coated and dry, guillotines for cutting it, while one of the large ventilators in the roof is fitted up with windows and a spiral staircase, and gives a beautiful view over Enfield and Epping Forest.

There is much all over the factory which is worthy of note, but our space here is limited, and we must hurry back to the laboratory whence we started, to see the various testing operations to which we have only hitherto alluded, and which are here very complete and systematic. The emulsion as it goes through the various stages is tested repeatedly, and until these tests have been performed none of it is coated. By this means it is not only easy to localise at once any carelessness or error, and so detect the cause of any defect, but much useless coating and subsequent cleaning off is avoided, and a consequent economy effected. These tests are invariably performed with pyro and ammonia and with pyro and soda without bromide, the developer being one which all the plates are required to stand. Spots, uneven coating, and similar defects are looked for by exposing a large plate to light all over and then developing to get a deposit which should be perfectly even. In this way the emulsion is watched through its various stages until the finished plates are ready. They now undergo a double test, the first being one on the lines indicated by Messrs. Hurter & Driffield. Strips of the plates to be measured together with a standard plate are exposed in the step by step dark slide devised by Mr. Cowan to the light of a standard candle. Overhead swings a seconds pendulum, and the exposure is performed by pulling out a row

of pegs one at a time at suitable intervals. When the strips so obtained are developed and dry, they are measured in a Bunsen photometer in the manner often described. One or two departures from the usual practice are to be noted. The photometer box itself is three feet long, the Schmidt & Hensch arrangement, which is extraordinarily sensitive, being substituted for the usual grease spot.

This test is always supplemented by another. A miniature studio in one corner of the dark room contains a patient and uncomplaining sitter in the form of a wax doll. A camera is fixed in one end of the studio in which is slipped the plate to be tested. One side of this studio is formed of a pane of ground glass, and outside this is burnt a piece of magnesium wire, the length of which is determined by the previously measured speed. In this way it will be seen that a practical test is given as well as one which some people might regard as rather theoretical. One most important matter in testing is not overlooked. It is insufficient to take one plate out of a batch, measure it, and from that say the speed of this batch is so-and-so. In the same batch the plates first coated may differ considerably in speed from those last coated, and it is only by taking plates here and there right through the coating that a fair average of their speed can be obtained, and this is a precaution which is not neglected by Messrs. Marion.

In this way, then, we passed through the works and found ourselves once more in the office, where we are met by Mr. F. Bishop, one of the partners in the firm. In concluding this notice we can only express our thanks to that gentleman and to Mr. Ashley Cowan once more, for the readiness with which they showed us the many interesting and clever arrangements which the works contain; many of these we have been forced to pass over without mention, but all are devised to ensure that high standard of excellence and uniformity which their products possess.

OBSERVATIONS ON PICTURE-MAKING.

[North Middlesex Photographic Society.]

When one is fortunate enough to be the friend of a President of a Society and in a weak moment succumbs to his flattering pressure to read a paper before his Society; and when, further, the President, out of his abundance, gives him a week to settle upon a title, it is then that the lecturer, in the desperation of the crisis, is tempted to welcome the first phrase that enters his head provided it has the ring and style of the usual lecture title, and he does so with the vaguest possible notions of what he is to talk about, and with little hope of being able to justify the title at all. So things happened in the case of your dutiful servant, who was stared in the face by the consciousness that he knew nothing about photography—a fact that will need no special demonstration to-night—and recognised that, if anything he could say to-night be worth the hearing, it could only be a statement of those few truths which hard work, failure, and repeated effort have formalised into mental furniture, so to speak. Certain of these two facts, he fell at once upon "Picture-making," there being nowhere else to fall. I am bold enough to say that, provided I stick to my last, there may be no great disadvantage in being only an admirer of photographs, and not a maker of them. You will think it not modest of me to say such a thing; but, then, I do not glory in membership of this Society, and so its great virtue has not possessed me. Some months back, the Society heaped hospitality upon me at an evening meal in Holborn, the sweet flavour of which, like Macbeth's amen, still sticks in my throat. On that occasion I learned how fine a thing it was to be a photographer, and be possessed of the great virtue which on that night enveloped every speaker and was known by the name of N. M. Modesty. My modesty, if I have any at all, is not, I fear, of the N. M. order; therefore, am I so bold as to say that, for our purposes this evening, there is no disadvantage in my being quite ignorant of the mysteries of the photographic art?

There are numberless ways in which the inborn talent of every photographer may find demonstration; but, primarily, they divide themselves into three—the scientific, the commercial, and the artistic. Perhaps the scientific progress and uses of the camera in late years give the most cause for wonder and appreciation. The realm of science is yet a new field, and it is possible that the future may show that photography will have done more than any other agent in unlocking the countless portals of Nature's marvels and secrets, and giving those marvels and secrets forth to the world in a widespread way undreamed of in old days.

In the commercial field, photography goes by leaps and bounds even at this day, and it is no great draught upon the imagination to picture to ourselves that, by payment of some small fee, no larger than we now pay for the *Daily Graphic*, that latest achievement which the camera has made possible, some great development of kinematography for instance, may show to the world absolute reproductions all alive of battles, public ceremonies, or what not, as they occur day by day. In fact, there seems to be no limit to the possibilities of photography, scientifically or commercially. But, artistically, when we come to that phase of it, we find a thing so different as to be almost another pursuit entirely. For let us understand that the artistic aspects of photography, as I shall define them to-night, preclude all technical questions and considerations; these may have distinct bearings, but I am powerless to discuss them, and shall deal only with the finished results, the picture; for, although the science of photography may perhaps help the attainment of such artistic results as might be thought desirable, yet the demands of art must first be established, in order that science may be directed towards them. Then, when we confine ourselves to the demands of art alone, we begin to understand why artistic photography is such a different thing to that of other kinds. Thinking for a moment of science and commerce as we are now using the terms, it is borne in upon our minds that their highest successes are high-water marks, so to speak, caused by the pressure of curiosity and cupidity respectively. This is perhaps a reckless summing up; but, at best, it represents the case broadly. Now, art is a little thing ready-made in each man's breast in a more or less degree, mostly less.

The struggle for existence does not call it forth, the adulation of the mass only degrades it. It is simply passion and emotion; technique scarcely counts, apparatus goes for nothing, the pressure in this case comes from within, and that makes the difference. But all these conditions of art have existed unchanged for ages, and so we find that art existed ages ago as good as any to be seen to-day. Should we expect to find more of it in the future than has been in the past? And now for the culminating question, Does the camera promise us more? It would seem that the field of art is already overtrodden, and that the camera will scarcely find a patch of virgin soil. We are stopped by the high boundary wall of limitations in photography so soon as we think to walk as far afield as did Ruysdael, Constable, and Turner, for the very reason that art is not an exact science, that it finds its sustenance in the passions and emotions of men rather than in their intellectual activity or in their experiments and calculations. For this reason is it like an old sweet tale which has been told and retold in a thousand ways according to the fancy of the teller, but never by any chance altered or extended without ceasing to be what it is.

Zola very finely described Art as Nature seen through temperament. That being so, why do not the countless devotees of palette and brush, though they paint on and strive to be original and see something freshly, in the long run see more than did Ruysdael, Constable, or Turner, when they walked the fields? They look at the same old nature, although it be through their own temperaments, and men may follow with cameras and meet with marvellous success, as we know they do; but they will not achieve more. Nobody for a moment expects that they will. As a matter of fact, they can never achieve so much, and for this reason.

The indefinable charm and fascination of a fine picture arises, not so much from the natural scene which was its model, as from the something which makes its first appearance in the actual process of painting—something that emanates from the artist, and makes him render the natural scene just so, and not just so. It is the *temperament* we have spoken of. It *is not* the correctness of portrayal, which may be absolutely correct or otherwise. If it were that correctness, possibly the camera would have a good chance; but it is the temperament through which nature is seen, and what I may ask is the temperament of a camera? The finest artistic temperament is displayed willy-nilly by the artist, and he is only conscious of it by the struggle that goes on in his brain, and the absolute concentration of his energies, which in a physique not robust may cause a palpable fatigue. It is bred by love of Nature, and a constant observation of her face, through all its smiles and tears, its frowns and sweetness. Every observation and experience of the artistic mind is stored up, we don't know where; and the more that is amassed the more is the mind tempered. When a picture is painted, all this stored-up richness plays its part, the painter's mind is permeated by it, and the work duly affected. Unfortunately, in the case of minds less receptive, less subtle in action, or warped by commercial and other influences, the temperament is impaired, the stored-up experiences crystallise into cheap mannerisms and tricks which are used for the speedy production of work, the obvious and catch-penny effects and other degradations only too prevalent. From one pole to the other, however, there is a highly graduated scale of work. Some of the finest landscapes never had an actual counterpart in Nature at all, but have been entirely the output of these stored-up feelings, sensations and facts. How different is this state of things from that of the photographer, who

has to take what is put before him, and who, in addition, has to deal with the endless faults of the lens, which won't see things as they should be seen—to wit, the defects of focus, undue sharpness or indistinctness of definition, violent ranges of definition, unequal definition and lighting abnormal perspective, astigmatism (spheres seen as egg shapes, and other similar atrocities), distorted perpendiculars, halation, and so on and so on, not to mention the further vagaries of toning and printing.

Now, we all agree that artistic photography makes no effort to pose as painting, and I will not add a quack to the cackle already heard upon the subject of palette *versus* negative; but perhaps you will permit me to say that, as Art is Nature seen through temperament, and that as the temperament of the camera, if it have one at all, is a somewhat perverted one, it follows that what artistic feeling there is in a photograph must be largely due to the photographer himself, and that such a fact places both artist and photographer on an equal footing where they had much better shake each other's hands than kick each other's shins, and, for my part, see here no difference between them. There is nothing fresh to be discovered in the *face* of Nature, each commonly do their best to preserve her smiles less clumsily, and this is the end of all landscape art.

It will always be found that the uninitiated, although quite prompt at expressing a preference for one picture before another, can never give a reason for their so doing; *i.e.*, apart from mere points of subject, association, sentiment, or such non-technical considerations. A more highly analytic or introspective spectator may be able to do so, and will perhaps express a preference much more forcibly; he may say, "I don't like that corner," or "That tree seems awkward," or "That piece from the house to the shore is lovely," but beyond such generalisations he will be unable to go, and to find a cause for his likes and dislikes will be out of his power. The trained mind alone is able to make a diagnosis, which it does by the help of certain standards or canons already fixed in the mind by the course of training through which it has passed. It finds that the displeasing part of the picture violates one or more of these canons, and that part which gives delight does so because it coincides with preconceived ideas as to what is most beautiful in this or that direction. It is, therefore, obvious that the duty of every one who wishes to make fine pictures is to come to some knowledge of these canons and laws and how they should be applied. He will do this best by studying the finest works of art, and trying to find reasons for his preferences; he will do it still, but less well, by reading books on the subject; and least well of all by hearing lectures. In most books it will be found that these laws are tabulated in a *very* precise and methodical way; but, as a matter of fact, the principles which give rise to them can be found running through all branches and phases of art. For instance, *gradation* may be made as much a matter of form as of tone, and the same may be said of massing, contrast, balance, repetition, and all the others. But, as, however, they can only be talked of one at a time, maybe there is no help for it.

Perhaps the most important thing in a photograph is composition, which may be defined as the disposition of the elements of a picture to the best advantage in relation to each other and to the whole. There is composition of line and composition of mass, but in landscape art the difference between the two is not very marked, although in ornament, for instance, there is a very strongly marked difference. Not much is to be gained at this moment in carefully dividing the subject into headings and sub-headings; but, roughly, it may be said that the art of composition embraces several principles, amongst which I may mention flow of line, massing, balance, repetition, even distribution and contrast. Many of these it is possible to have in one and the same picture. The principle of even distribution is usually only applied to ornamental art. An ordinary chess-board or a diaper pattern is sufficient instance of it, from which it will be seen that the method has no great place in landscape art. Nevertheless, I will show you a view which is strongly dominated by this principle, and you will see that its power is to give quietness, modesty, and tenderness to a view. This is a scene of Redlands Woods, taken by my good friend, Mr. F. H. Evans, who has been kind enough to lend a score of slides for our purpose to-night. Here it will be seen that the leaves on the trees and on the ground are so equal in scale and tone, owing to the diffused lighting, that only the larger boughs and the ivy on the trunks *tell* at all in any strength.

Of course these strong portions and the delightful detail are the saving of the picture, and go to make its charm. A modern black-and-white artist, working in wash, and therefore shirking all the small drawing, as they do nowadays, would be hopelessly tame and weak with such a treatment. This slide is parenthetically shown, however, as an exception to the rule that even distribution is not often found in landscape art. I should prefer to start with the principle of *unity*, or singleness of subject, as we may call it.

A picture should have something to say; but it should not say too many things. It is usual with beginners in art to stumble upon the side of putting too many interests into their work. When an idea, a motive, a theme—call it what you will—has been decided upon for the subject of a picture, we shall not do wrong in giving it every chance and every square inch of room that it demands for its support. The spectator will not trouble to hear a very long tale, and, if we give him a dozen incidents all of equal importance, he will be impressed by none. His attention refuses to divide itself up over, it may be, a house, a tree, a mountain, a stream, a horse, a cart, children playing, clouds towering, birds flying, and so on, and so on, each of which clamours as loudly as another. Something should be allowed a first place. Supposing it to be the house, then all the other items can be included, if necessary, but in such a way that the spectator need not notice them unless he likes; but he must be made to see the house. Here is a very rough print of John Sell Cotman's famous water-colour, *The Draining Mill, Lincolnshire*.

The impressiveness of this wonderfully dignified work is due to the fact that it is a picture of the mill pure and simple, all else there is in the picture only working towards the one effect, which the mill initiates. The bank of the pool is very simply massed together with the mill, and thus not only supports it, but becomes a part of it. The pool, while giving in a romantic way an echo of the sky, at the same time repeats the story of the mill in its reflections. As for distracting elements, there are none. The next illustration is another mill, this time by David Cox. The same simplicity is here. There is no absorbing interest anywhere but in the windmill. The sky is so quiet as to be almost flat, the foreground, mid-distance, and distance are also broad and *flat*, which is to say even in tone; and nothing in them is strongly made out. I would also draw your attention to the horizontal composition of these parts, by which the vertical lines of the mill gain a dignity and importance, two qualities which would be the sum of an ordinary person's after-impression, supposing him not to have seen the work before. Yet another mill, this time by a photographer, and, moreover, by your esteemed member, Mr. Samuel Wall. The simplicity, dignity, and charm of this very lovely composition are due to exactly the same principles as are those of the two prints you have just seen. Yet it must not be thought that windmills alone supply these necessary qualities. I was tempted to include this slide because it composes so well—the foreground, the boats, the distance, and sky, all being beautifully in harmony; and I also wish you to appreciate how much of Cotman and Cox there is in your fellow-worker, Mr. Wall. Nevertheless, windmills usually make dignified subjects, by reason of their exposed position.

Now, we have another picture by the same worker, taken one day when he was antagonistic to Cotman and Cox. It has numberless fine points, which we will not dwell upon now, for I show it on account of its one unsatisfactory point, the divided interest of its composition. As it stands there is enough material for two pictures, and the eye jumps from the house to the bridge, and back again, and finds no place to settle happily. It will be found that all the styles of composition and all laws of picture-making can be made to serve this important end—*unity of interest*. Given a motive or theme, and we can make lines to lead the eye to it, masses to support it, reflections to echo it, gradation to lead up to it, contrasts to enforce it, and so on in endless resource. In a moment we shall have a slide (which you have seen before), made by another good friend of mine, your worthy President. But first I ought to say that these slides are lent to-night simply to help the coherence of my remarks, the owners do not regard all of them as triumphs in photography or slide-making, and I do not court your criticism in regard to them. What remarks I may make apply to matters entirely outside photographic technicalities, and outside matters of taste also, upon which there can be no disputation.

In looking at photographs I have come to the conclusion that mere luck can make or mar. There is no persuading or liberty taken as there is in sketching. If there is luck and you know the moment to seize it, a really fine thing may be ready to hand; but without such luck you are courting doubtful success, if not failure.

Now look at this picture. First of all, there is unity of interests, about which I have been preaching, fairly kept, the arch is evidently the chief motive, it is larger than anything else; it has the important place in the composition and is strongest in colour. Very well, the eye goes there first, and takes it all in; but here is the misfortune, it is so quickly satisfied that it leaves the arch at once and wanders down the stones of the brook, *which it likes much better*, for in them there is more variety and richness and much more interest. But the deep black of the arch call the eye back again so lustily that back it goes conscience-striken, this time it may discover the branches and twigs across the portion in the shadow,

and may stop a little longer. All this can mean nothing but the arch is "doing the *heavy*," if you will allow me so much slang, under false pretences; and really there is nothing very absorbing about it in spite of the prominence it takes. Probably the artist himself felt this, for I will show you another view where the interest is transferred to the boulders. But first let me point out another piece of ill luck, which is, that the two trees to the right and the two nearer edges of the arch are all nearly equidistant; that they make right angles with the top of the wall, which is itself a decided horizontal line. These points refer to principles which will be reverted to later.

Now let us look at the next slide. Here is the same subject making a very beautiful picture. The water rushing over the boulders becomes the chief object of interest. They have the highest light and the deepest shades. The arch being now smaller and further away has become secondary, but is, nevertheless, more interesting than it was before, and yet it does not detract from the water and boulders, for its softened tones echo those of the foreground while they give a richer spot to the mid-distance. The equidistance of the vertical elements is not so marked, the horizontal wall has gained a dip somehow in the centre, while its edge has become softer in quality; and lastly, the extreme distance has a finer character. All these improvements are the outcome of a better selection; and selection is the photographer's only substitute for the painter's licence of omitting, inventing, and altering.

F. Colin Tilney.

(To be continued.)

FRIESE GREENE'S IMPROVEMENTS IN RAPID PRINTING BY PHOTOGRAPHY.

The following is a brief description of Mr. Friese Greene's improvements in the production of prints by photography, and in apparatus for the purpose.—

"I print successively by means of photography a number of impressions from the same photographic or other negative, or from the same series of negatives, upon a continuous band of sensitised paper or other sensitised material, as this is caused to travel continuously in contact with a translucent cylinder which bears or carries the negative or negatives, the said cylinder being lighted internally, preferably by one or more incandescing electric lamps.

"In carrying out the invention, when the negative or negatives employed are photographic negatives, I use negatives which have been taken upon a flexible translucent material such as a thin sheet of celluloid, and I place this sheet upon a supporting cylinder of glass in such manner that the sheet bearing the negative or series of negatives surrounds the cylinder. Within this cylinder I place one or more lamps. Over or under the cylinder, and in contact with the celluloid sheet thereon, I carry a band of sensitised material from a roll or otherwise, this band being so guided that there is always a part, say, several inches, of its length in contact with the celluloid sheet and this part of the band being maintained taut. Rotary motion is given to the cylinder and forward motion at the same surface speed to the band with the result that every section of the band equal to the circumference of the cylinder has printed upon it by means of the light a positive impression from the negative or negatives on the cylinder, the same picture or pictures being produced upon every successive section of the band. On leaving the cylinder the band is carried to and through fixing and developing baths; or, if it be required to print upon both sides of the band, it goes from the first cylinder to a second and similar cylinder, where it is printed in like manner upon its second side; it then passes on to the fixing and developing baths.

"When the negatives employed are not photographic negatives, they may, for example, be transparencies or sheets having the parts that do not constitute the design in black, red, or other non-actinic colour, and the other parts, that is to say, the design transparent, or *vice versâ*.

"It is not essential to employ the glass cylinder described if the sheet that bears the negative or negatives is strong enough to be self-supporting."

NOTES FROM THE WEST OF SCOTLAND.

Some time ago, we were enabled to inform our readers that a movement was on foot in Glasgow and the surrounding district with the view of having another International Photographic Exhibition on similar lines to the one held in Glasgow during the autumn of 1891, and which proved such a big success for its promoters.

No doubt the Exhibition would have been held this autumn, but it was found that several circumstances stood in the way of arranging for such, the chief of these being the impossibility of obtaining the Fine Art Institute in Sauchiehall-street, which was secured a long time ago for the autumn months for the Burns Exhibition.

We are pleased, however, to be able to state that all obstacles in the way of securing these fine rooms for the autumn of 1897 have been overcome, and that Mr. Goodwin, on behalf of the Council of the Glasgow and West of Scotland Association, has signed a contract for the entire Institute's accommodation during the months of September and October of next year.

This scheme will be carried out with much vigour, and amateurs and professionals, both north and south of the Tweed, should keep the autumn of 1897 in view, considering the importance of this event.

Fifteen thousand persons visited the Corporation Camphill Exhibition during the first ten days of its opening.

The Inquirer.

*** *In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* Journal *useful and instructive.*

Image in Chromate of Silver.—Chromatic writes: "Is there any method by which I can convert an ordinary silver-image negative or positive (untoned) into chromate of silver? I want to utilise the colour of the silver salt for transparencies and positives of a particular class of subjects."

Storing Negatives (To "Cimex").—Put a little varnish (if tacky, so much the better) on the spare part of the negative. When nearly dry, press on the label. But why not write on the face what you require with a lead pencil? This will show sufficiently, and cannot be rubbed off. Or you can scratch it neatly with a strong pin, showing clear lettering.—W. G.

Cement for Glass and Paper.—In reply to the query of "Cimex" in The Inquirer column of last week's British Journal of Photography, I may say that I find it a good plan to make negative labels of albumenised (unsensitised, of course) paper, sticking them on to the film side of the negatives by simply wetting the albumen. They should be put on before varnishing, the latter operation giving them greater durability.—Drinkwater Butt.

Wet Plates and Alkaline Development.—J. B. writes: "In connexion with the query on this subject last week, I have for a long time employed ferrous oxalate in the intensification of wet plates, and I find it decidedly superior to pyro or any other form of alkaline development. There is less tendency to the fault complained of by your correspondent, viz., stain from insufficient washing, it gives greater density, and a colour that more nearly resembles ordinary silver development. In order to get the full effect, it is necessary to continue the application for some time, as the image formed by the first development seems to hinder the penetration of the intensifier. It should also be borne in mind that the density increases in drying more than is the case with pyro and silver."

Wet Plates and Alkaline Development.—In reply to "A Beginner in Wet-plate Work," may I add to what was said last week that his failure is, without doubt, due to insufficient washing. There are several methods besides the special use of a solution of salt by which the last traces of silver can be converted, but perhaps the simplest is to apply the pyro (or other reducer) and the bromide to the plates before adding the alkali, in which case any trace of free silver is converted into bromide. It is the silver and alkali that react upon one another, not the pyro and silver, as *plain* pyro can be applied to a film containing decided traces of silver. The addition of a few grains of nitrate of ammonia to the developer will prevent the mutual reaction referred to, and at the same time act as a restrainer of development.—Syntax.

CEMENT FOR LABELS (To "Cimex").—If your correspondent will try the simple plan of adding a little loaf sugar or a few drops of glycerine to the adhesive, I think he will find his difficulties disappear. The cause of the labels becoming detached is that the mountant, whether paste, gum, or gelatine, becomes too dry and brittle, and then loses its attachment for the glass, though good paste does not usually exhibit this weakness. The sugar or glycerine supplies sufficient hygroscopic matter to prevent the state of excessive dryness, and preserves the adhesion of the labels. If "Cimex" lives anywhere near a bookbinder or a shoemaker, either will supply him with a paste that answers admirably for such work as he speaks of, but I should not advise him to mount photographs with it.—W. L. BROWN.

CEMENT FOR GLASS AND LABELS (To "Cimex").—PHARMACIST writes: "If 'Cimex' wants a good and reliable cement for labels, I will give him a recipe I have used for many years, and which I have occasionally employed for mounting photographs, my only reason for not so employing it regularly being that it necessitated being used warm; and, besides, the prints are very difficult to remove if not placed in proper position on the mount at first attempt. Let him procure at any chemist's an ounce or two of gelatine lozenges—not the glycerine jujubes, though I dare say these would answer, but the old-fashioned round, flat lozenges. Cover these with cold water, and allow to soak for some hours; then dissolve by heat and thin to a convenient consistency. It requires liquefying by heat before use, and will keep indefinitely, owing to the sugar and flavouring the lozenges contain."

CLEANING OFF OLD NEGATIVES.—At the risk of overdoing the advice to W. Heward *re* cleaning old negatives, a simpler and cheaper plan than any yet published is as follows (this may be of use to others as well):—Put some washing soda into a saucepan of water; make it boil. While heating, take a pan and place a negative in it film uppermost; on it at each end place a match, if you are a smoker, or any other small object. Upon these put another glass, film downwards, leaving a space between. The third can go flat on the second, matches and plates as before, until the pan is full. Then pour in your solution, hot and strong. By the time it is cool enough to take out the plates, the film will be detached, or may be with the edge of one of plates. Sometimes a very obstinate case requires a second dose. Rinse in clean tepid water. If wanted chemically clean, follow with a washing of acidulated water.—W. G.

X RAY WORK.—MONA. This correspondent writes a long private letter to Mr. Watmough Webster, asking for advice *re* Röntgen ray work, although Mr. Webster in his paper on this subject specially asks strangers to apply through the JOURNAL if desiring information regarding this or any of his contributions. Briefly, "Mona's" focus vacuum tube has gone wrong. It had a brass cap cemented on at one end, and thus had gradually come loose, and the tube has lost its power. "Mona" wishes to know if this is a customary way to construct these tubes, and wishes to have Mr. Hicks' address so as to send the tube to him for repair, the maker ignoring all "Mona's" letters.—Reply to "Mona:" You do not say whether the brass cap is essential to closing the tube or not. It is not the usual way of making these tubes to seal an end with a metal cap cemented to the glass tube; usually the tube is complete of itself, the vacuum being made by means of the small projecting glass tube that is seen as part of these tubes. It has been recommended to increase the potency of the tube by putting a metal—tinfoil—cap outside the anode. Perhaps "Mona's" tube had the brass cap padded for that purpose. If the cap was needed for closing the tube, the latter would, of course, be destroyed upon the separation. The most probable cause of the failing of the tube is that "Mona" has "sparked" it—a very common occurrence with those not used to manipulating vacuum tubes. If, through one connecting wire springing or otherwise coming in close proximity to the tube while the other wire is connected with an electrode of the tube, a spark passes from wire to tube, the latter is pierced with an invisible micrescopic aperture, and the atmospheric air enters. "Mona" will find that a three-inch spark coil is as low as possible for doing *quick* work with. Mr. J. J. Hicks' address is 8, 9, and 10, Hatton-garden, E.C. But "Mona" will find that no one is likely to repair a spoiled tube.—G. WATMOUGH WEBSTER. P.S. "Mona" may be able to improve the value of his tube by means of the plan suggested by Mr. Porter, which in all probability the Editor may publish this week.—G. W. W.

Our Editorial Table.

CATALOGUE RECEIVED.

S. J. LEVI & Co., 71, Farringdon-road.

A VERY comprehensive catalogue of 112 pages, illustrating a large variety of photographic, stereoscopic, microscopic, optical, and electrical apparatus. The trade in particular will find the volume extremely useful on account of its completeness, scarcely an item of modern photographic requirements being denied mention.

VIEWS OF ST. BARTHOLOMEW THE GREAT, WEST SMITHFIELD.

By FREEMAN DOVASTON. With Notes by E. A. WEBB.
London: F. Dovaston, 5, George-street, Euston-road.

ON a previous occasion we wrote in commendatory terms of a collection of half-tone views of *St. Paul's Cathedral*, from Mr. Freeman Dovaston's negatives, and the same indefatigable worker has in the present *brochure* got together a number of similar reproductions of a series of negatives of that interesting church, *St. Bartholomew the Great, West Smithfield*. Keeping in view the difficulty of photographing the far-from-well-lighted interiors, the views of the choir, the baptistry, the tombs, the West door, the ambulatories, and other parts of the church are very well done, while Mr. Webb's notes are terse and useful, and the *brochure* (which sells at 1*s.* net) may, as a whole, be commended to all lovers of Old London.

THE "P. S." PLATE (ACTINOGRAPH No. 80).

Marion & Co., Soho-square, W.

IN sending us for trial some of their new plates—the "P. S."—Messrs. Marion draw our attention to their announcement that, following the recommendation of the Speed Committee appointed by the Royal Photographic Society, the speed of these plates is determined by the Hurter & Driffield method by using the same developer as advocated for use in actual practice, viz., pyro and soda. We employed pyro soda in the development of the plates we exposed, our experience of which was entirely satisfactory. The emulsion is exquisitely sensitive, clean, and fine in the green, and yields negatives of a peculiarly harmonious and well-gradationed character. We could not wish to work with a better or more carefully prepared plate than the "P. S."

THE ELEMENTS OF STEREOSCOPIC PHOTOGRAPHY.

By C. F. SEYMOUR ROTHWELL, F.C.S. Bradford: Percy Lund & Co.

MR. ROTHWELL knows his subject well, and writes of it very clearly; his book, in fact, is well calculated to be of assistance to the beginner in this fascinating branch of work. Alluding to the size of plate to be used, he strongly condemns a favourite size of our own, $6\frac{1}{2} \times 4\frac{1}{4}$, on the ground that plates of that size are difficult to obtain. "It has," he says, "its chief advocates in people who are interested financially in the sale of appliances of this size." We have used the size for years for stereoscopic work, and have no financial interest in it, but we occasionally find it convenient to use two quarter-plates instead of one $6\frac{1}{2} \times 4\frac{1}{4}$ plate when the latter does not happen to be at hand. For the rest, we can thoroughly recommend the book, merely adding, however, that the author has overlooked mention of probably the simplest method of stereoscopic transparency making by contact, viz., where the negative is clamped in position over an aperture approximating to its own size, and the transparency plate in the two successive exposures is moved from side to side.

PRACTICAL RADIOGRAPHY.

By H. SNOWDEN WARD. London: Dawbarn & Ward, 15, Farringdon-avenue, E.C.

PREFACED by a brief outline of the electrical principles involved in radiography, we have in Mr. Snowden Ward's ably compiled little manual chapters on "How to Make an Accumulator," by Mr. A. E. Livermore, and "How to Make an Induction Coil," by Mr. E. A. Robins. The remainder of the book treats of the electrical and photographic branches of the main subject, and well realises its introductory claim of being of service to photographers insufficiently acquainted with electricity, electricians insufficiently acquainted with photography, and surgeons insufficiently acquainted with both. There are numerous illustrations, and the handbook is one of the most practical of the many volumes so far called into existence by Professor Röntgen's remarkable paper and experiments.

News and Notes.

We are sorry to learn that Mr. Alexander Johnston, F.R.P.S., photographer, of Wick, died at Edinburgh on June 21.

The Photographic Club.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, July 8. Members' Open Night.

Up-to-Date.—Physician of the new school, after turning X rays on patient: "Your case is a somewhat complicated one. There is a slight trouble with your left lung, and I observe enlargement of the liver, and fatty degeneration of the heart. Kindly hand me those two sovereigns in your right-hand trousers pocket, and I will prescribe for you."

In the year ending 1896, May 10, photographs of the sun were taken at Greenwich with the Dallmeyer photo-heliograph, mounted on the terrace roof of the south wing of the Physical Observatory, on 229 days, and of these 459 have been selected for preservation, besides fourteen photographs with double images of the sun for determination of zero of position angle.

Albert Medal.—The Albert Medal of the Society of Arts has been awarded, with the approval of H.R.H. the Prince of Wales, the President of the Society, to Professor David Edward Hughes, F.R.S., "in recognition of the services he has rendered to Arts, Manufactures, and Commerce by his numerous inventions in electricity and magnetism, especially the printing telegraph and the microphone."

A few weeks ago I alluded to the useful purpose photography had served in the coaching of the Yale crew in America. There seems no earthly reason why it should not serve a still more useful purpose on the turf. Not only at the finish of a race, but at the other end as well, it might be brought into requisition. An instantaneous photograph of the start of some races I have seen would make a particularly interesting study for the handicapper.—*The Weekly Sun.*

Failures.—The following passage, from a speech by Lord Kelvin, is worth recording: "One word characterises the most strenuous of the efforts for the advancement of science that I have made perseveringly during fifty-five years, that word is *failure*. I know no more of electric and magnetic force, nor of the relation between ether, electricity, and ponderable matter, nor of chemical affinity, than I knew and tried to teach my students of natural philosophy fifty years ago in my first session as professor. Something of sadness must come of failure; but, in the pursuit of science, inborn necessity to make the effort brings with it much of the *certaminis gaudia*, and saves the naturalist from being wholly miserable, perhaps even allows him to be fairly happy, in his daily work. And what splendid compensations for philosophical failures we have had in the admirable discoveries by observation and experiment on the properties of matter, and in the exquisitely beneficent applications of science to the use of mankind with which these fifty years have so abounded."

Society of Arts Medals.—The Council of the Society of Arts have awarded the Society's silver medals to the following readers of papers during the session 1895-6:—W. J. Dibdin, F.C.S., for his paper on "Standards of Light;" A. J. Hipkins, for his paper on "The Standard for Musical Pitch;" A. A. Campbell Swinton, for his paper on "Röntgen's Photography of the Invisible;" Dr. D. Morris, C.M.G., M.A., for his paper on "Bahamas Sisal Industry;" Edward W. Badger, for his paper on "Fruit and Vegetable Drying;" E. W. Moir, M.Inst.C.E., for his paper on "Tunnelling by Compressed Air;" Col. R. G. Woodthorpe, C.B., R.E., for his paper on "The Shan Hills, their Peoples and Products;" J. H. Glass, C.I.E., for his paper on "The Great Landslip at Gohna, in Gurhwal, and the measures adopted to Prevent Serious Loss of Life;" G. W. Christison, for his paper on "Tea Planting in Darjeeling;" Frank Cundall, for his paper on "Jamaica in the Past and Present;" G. Scott Elliot, for his paper on "The Commercial Prospects of English East Africa and British Central Africa;" Charles R. Valentine, for his paper on "The Colonies and the Supply of Dairy Produce and Products of Petite Culture;" Gleeson White, for his paper on "The Poster and its Artistic Possibilities;" William Burton, F.C.S., for his paper on "The Palette of the Potter;" George Simonds, for his paper on "Bronze Casting in Europe."

A Question of Colour.—At the present time, when so much is being done by way of experiment in colour printing and straining after the utmost effect obtainable with the three primary colours, it occurs to a studious mind that the extreme fineness of the subdivision of these three colours necessitates as much extreme care in their interpetation by the printing press. It only needs to run through one edition of such a piece of colour work to note the inequality. Where the yellow predominates ever so slightly, the effect in the result is crude; if the red predominates, then the picture looks too fiery, and, if the blue predominates, too cold or inclined to green or to purple, according to its relative value to the other two colours. It is to obviate this that the introduction of a suitable shade of light grey printed in conjunction with the three primaries has the effect of mixing with and binding together the three raw colours. Heliochrome inks, so called from their being slightly neutralised or toned down by the admixture of small proportions of their complementaries (grey) bring the three raw colours into harmony; yet does this only in relation to each individual colour. Now, by *printing on grey*, obtained by mixing the same three inks in proper proportion, the effect is still further to harmonise and bind together the three colours. This principle is well known in chromo colour printing. To make a key block and print in black or photo brown and let the red, yellow and blue take their chance, is to get the coloured-up photo look in the result. Instead of this, to get the utmost subdivision in three primaries, of which the blue is the most important, giving the vital drawing of the picture, and to print the key block a suitable grey, is to aid the blue in its effect as far as density, depth, and the drawing in the picture are concerned. —Joseph Scholefield in *The Practical Process Worker.*

During last year M. Flammarion made some interesting experiments as to the effect of lights of different colours upon vegetable growth (*Bull. Soc. Ast. France*, June). On July 4, eight identical sensitive plants, which had been sown at the same time, were selected for experiment. These were placed two by two in similarly constructed glass boxes, of which the sides were of different colours, one being red, one green, one blue, and another of ordinary clear glass. All were exposed to precisely the same meteorological conditions throughout. The rates of growth were as follows:—

	Red.	Green.	Blue.	White.
	m.	m.	m.	m.
September 6	0·220	0·090	0·027	0·045
,, 27	0·345	0·150	0·027	0·080
October 22	0·420	0·152	0·027	0·100

Thus, while the plants exposed to blue light made no progress whatever, those exposed to red increased their height fifteen times. The latter, moreover, acquired an extraordinary degree of sensitiveness. Similar results, but not so strongly marked, were obtained with geraniums and other plants. The fact that the plants exposed to white light grew less rapidly than those which were under red glass, although receiving the same amount of red radiations, seems to suggest that the presence of blue light in the former case not only did not accelerate the growth of the plants, but actually retarded it.

Royal Cornwall Polytechnic Exhibition.—The following are particulars of the classes and prizes for the photographic section:—In all cases state whether the work is professional or amateur, and name process of production. All work sent for competition must have been executed within eighteen months of the date of this Exhibition. *Carte-de-visite* portraits are excluded from exhibition, except when illustrating some special process or novelty. All enlargements for competition must be the work of the exhibitor. Information respecting the photographic department may be obtained from Mr. W. Brooks, Laurel Villa, Wray Park, Reigate (member of the General Committee). *Professional.*—Medals are offered by the Society for meritorious productions in the following subjects:—Outdoor photography: 1, Landscape, not less than 20 by 16 inches; 2, Landscape, 12 by 10 inches and under; 3, *Genre;* 4, Architectural (exterior); 5, Instantaneous, including Marine; 6, Animals; 7, Enlargements. Indoor photography: 1, Portraits, not less than 20 by 16 inches; 2, Portraits, 15 by 12 inches, and under; 3, Home Portraiture; 4, Still Life, Flowers, &c.; 5, Interiors, Agricultural or otherwise; 6, Photomicrographs; 7, Enlargements. *Amateur.*—1, Landscapes; 2, Architectural, exterior or interior; 3, Hand camera work—not less than twelve examples; 4, Instantaneous, including Marine; 5, Still Life; 6, Enlargements. *Photographic Apparatus.*—With a view to offer facilities to manufacturers to bring their specialities prominently before the public in the West of England, the Society purpose this year to apportion space for photographic apparatus generally, including the lantern and its appliances.

Photography and the Royal Family.—At the recent visit of the Prince and Princess of Wales and the other Princesses to Machynlleth, it may be of interest to know that the Princess of Wales was carrying her hand camera about in the Plas Machynlleth (the seat of Lady Londonderry), taking chance groups of the friends as they talked or played croquet on the lawn. That the interest and amusement caused to Royalty by photography and photographers is by no means small, the following amusing incident will show: There were to be two young trees planted in the grounds, one by the Prince of Wales and the other by the Princess. When the royal visitors had, with Lady Londonderry and a few friends, departed to witness the ceremony of planting, the Prince having taken the spade in his hand, a peculiar noise was heard by them. However, they took no notice; but, upon hearing the noise, "as of the lower jaw of a skeleton," repeated several times, the Prince, Princesses, and the nobility collected made for to discover the meaning of these uncanny sounds. Long and loud was the laughter by all when it was found that Mr. B. Pearce and Mr. Fred Coop were concealed in the adjoining bushes, and that it was the snap of their Thornton-Pickard shutters which had caused the investigation. The undaunted photographers snapped off the Royalty when laughing boisterously, and highly amusing were the excellently successful groups produced under such marked difficulties—seven p.m. The two above photographers on the same morning had the honour of photographing the Royal group at the Plas before their temporary departure to Aberystwith to open the University College of Wales, recently built there. Lord Herbert, son of Lady Londonderry, declared that the group referred to could not be better, and that it was a perfect likeness of all. Very gracious were the royal visitors to the photographers, as is further exemplified by the fact that, at the station on Saturday morning, previous to their departure, the Princess sat down in the carriage again at the request of the photographer, and allowed a picture to be taken.

Edison's New Electric Light.—A notable example of the stimulation of invention by new discoveries is found in the latest work of Edison which follows the discovery of Röntgen and the fluoroscope of his own invention. This latest invention is a fluorescing lamp in which is found the promise of the artificial light of the future. The lamp appears to have all the qualities requisite for perfect illumination. The light is mild, but effective; it is diffusive, like daylight. It gives off no perceptible heat, which latter quality goes to show that its economy has no parallel in other kinds of artificial illumination. One form of the lamp consists of a highly exhausted oblong glass bulb, having wires sealed in the ends, each wire being provided with a small plate inside the bulb, one of these plates being inclined, to cause a distribution of the rays over the side of the lamp. The inner surface of the lamp is covered with a granular mineral substance, which is fused on the glass, and is highly fluorescent. When the lamp is excited by connexion with an induction coil, the fluorescent material becomes luminous. Originally Edison used calcium tungstate for his fluorescing material, but, by trial, he found that the vacuum soon deteriorated, and, after a long series of experiments, has discovered a fluorescing material which does not affect the vacuum, while it has a higher efficiency than the calcium tungstate. Mr. Edison thinks that the fluorescing material converts all of the X rays into light. He has a theory as to the manner in which the light is produced. The crystals are

composed of light and heavy particles, and the impact of the waves produces a stress in the crystals which causes the emission of light. Mr. Edison describes these waves as sound waves, because they differ in their mode of vibration from ether waves. Their motion is infinitely more rapid than that of sound waves, with which we are familiar; they are comparable as regards velocity with electric or light waves. As to efficiency, the fluorescing lamp produces light at the rate of 0·3 of a watt per candle power. When this is compared with 3 watts per candle power for incandescent lamps, and ½ watt per candle power for arc lamps, it will be seen that there must be great economy in the fluorescing lamp.—*Scientific American.*

ARE RÖNTGEN RAYS POLARISED?—Mr. J. William Gifford writes to *Nature:* "Mr. L. Casella has made for me a Crookes' tube, having as the anode a platinum window sealed into the end of the tube opposite the cathode, which is the ordinary aluminium disc. Owing to the glass sealing, only a small portion of the platinum, about 3 mm. in diameter, is free to act. The light from all but this portion was screened off by thick glass discs and a brass disc, these having each an aperture in the centre. The result with the fluoresceut screen was at first poor, because the vacuum was too low; but, as that got higher, it improved, and I was able to electrograph a part of the hand by the rays giveu off by this small platinum window in fifteen seconds, the plate being two and a half inches from the window. An ordinary focus tube takes thirty seconds to produce the same effect under similar conditions, but gives better definition. With the platinum window tube, though the bones are defined on the fluorescent screen, there seems to be too much white light, and the difference between bones and flesh is less marked. The tilted platinum of a focus tube apparently reflects most of the cathode rays, but transmits some. Compare the behaviour of the platinum in both tubes with the action of light on glass. With both glass and platinum, part of the rays are transmitted and part reflected, the proportion varying with the angle of incidence; but, with both, those rays which are perpendicular are apparently transmitted. If the glass be tilted at the proper angle, the reflected rays and a small part of the transmitted rays are polarised. Suppose the plate of glass in the position of the platinum window, and the source of light a luminous point within the tube; although most of the transmitted light would be radiated direct from the luminous point, part would be rays which had been polarised by reflection from the walls of the tube. The analogy would still hold good, for we know that, as far as X rays are concerned, glass behaves very similarly to platiuum, for these rays are, under suitable conditions, given off by both. These considerations and the appearance of microscopic preparations containing bone undecalcified when examined by low powers and ordinary light under Nicol prisms, lead me to hazard the suggestion that a bare possibility exists of X rays being polarised cathode rays. Were this so, the two kinds of X rays described by several observers would be explained, and we should also understand why those who have tried to polarise these X rays should have failed, the rays being already polarised. If this view is correct, extinction of the X rays should be caused by reflection from a second platinum surface at the proper angle. Whether this would succeed at atmospheric pressure I know not; the experiment should be tried *in vacuo*, and a tube constructed specially for the purpose. The window tube has, at all events, proved that a quantity of cathode rays, with some X rays, may be transmitted through moderately thin platinum under these conditions."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
6.....	Bradford.....	*Development.* G. Swaine.
6.....	South London	*Cameras and their Varied Forms. Lenses, Stands, &c.* C. H. Oakden.
7.....	Brixton and Clapham	Ordinary Meeting.
7.....	Gospel Oak	*Photographic Chemicals.* H. Billingsley.
7.....	Hackney.....	*Exposure.* W. E. Debenham.
8.....	Photographic Club	Members' Open Night.
11.....	Borough Polytechnic.....	Excursion: Bostal Woods or Stratford-on-Avon.
11.....	Darwen	Excursion: Hoghton Tower and District. Leader, Jno A. Hargreaves.
11.....	Gospel Oak	Excursion: Totteridge and Mill Hill.
11.....	South London	Excursion: Shepperton, for Walton-on-Thames. Leader, C. E. Fortune.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JUNE 25,—Mr. R. Beckett in the chair.

The HON. SECRETARY read the annual report of the Committee, together with the balance-sheet, from which it appeared that the Associatian was in a healthy financial condition, with a balance in hand of 39*l.* odd. During the year a heavy loss had been sustained in the death of Mr. Traill Taylor, one of the Trustees, the vacant post being filled by the appointment of Mr. A. Haddon, whose office of Curator is now held by Mr. F. B. Grundy. In consequence of removal from London, Mr. Atkins has resigned the Recordership, and, in recognition of his services, he was elected an honorary member. The Committee regret that Mr. Henderson's offer of five guineas, coupled with a similar amount from the Association, for the most valuable papers read during the session had not been responded to as expected, but Mr. Henderson has consented to the sum being held over for disposal on the same lines at a future date. The Committee also wished to impress upon the members the desirability of their co-operation with the officials in rendering the meetings as attractive and interesting as possible.

Mr. Henderson proposed that the report and balance-sheet be accepted. This was seconded by Mr. Freshwater and carried.

The election of officers and committee for the ensuing year then took place with the following result:—*Trustees:* Messrs. A. Haddon and J. B. B. Wellington.—*Committee:* Messrs. Bayston, R. Beckett, R. P. Drage, T. E. Freshwater, J. E. Hodd, J. S. Teape, E. J. Wall, and W. D. Welford.—*Curator:* Mr. F. B. Grundy.—*Librarian:* Mr. H. C. Rapson.—*Hon. Secretary and Treasurer:* Mr. P. Everitt.

Mr. Bayston showed a print of a "double" taken in an ordinary camera in a very simple manuer by the insertion of a suitable piece of card midway between the lens and the plate, which protected one-half of the plate during the first exposure, after which it was shifted across, the subject re-posed, and the second exposure made. If the camera is not moved, hardly any distinctiou can be seen between the two exposures.

The Hon. Secretary laid on the table the two portraits of the late Mr. Traill Taylor which he had been instructed to frame, and which he had now had done.

The consideration of the alterations to the rules, and further business of the annual meeting were deferred to the next meeting.

PHOTOGRAPHIC CLUB.

JUNE 24,—Mr. Thomas Bedding in the chair.

Mr. Fry passed round some prints upon some defective paper which had been shown at the previous meeting.

Considerable discussion took place upon the probable cause of the defect which had been alleged to be due to the paste with which the labels were attached to the packets of paper, but no definite conclusion was arrived at.

Mr. Haes showed some prints made upon Dr. Liesegang's collodio-chloride paper. The prints were nine years old, and were as good as ever they were.

Mr. FOXLEE said that Mr. Bruce, of Duns, had been using the collodio-chloride process commercially for twenty years. He (Mr. Bruce) had never met with a faded print. He coated his own paper with emulsion purchased commercially—Mr. Foxlee thought from Dr. Liesegang.

Mr. Bridge showed what had been a microscopic picture of himself—made by Mr. Williams—the image of which had entirely disappeared. This was due, it was suggested, to the use of a varnish made with absolute alcohol, which dissolved the collodion and so destroyed the image.

Mr. Isenthall showed some radiograms of large dimensions. The entire arm, the leg from the knee downwards, and the chest and trunk of a man were amongst the examples. The negatives were made on plates about twenty-four inches long.

The subject for discussion which next occupied the meeting was

TONING SILVER PRINTS.

A general talk upon combined toning and fixing baths, the possibilities of toning after fixing, the advantages of adding platinum compounds to the gold bath, and the many technicalities of the various processes in vogue concluded the programme.

Hackney Photographic Society.—June 23, Mr. R. Beckett presiding.—A long and very useful discussion was held on the subjects included in the lectures on *Development* and *Printing with Silver Paper* respectively, given at preceding meetings. Mr. Dean rendered report of the excursion on the preceding Saturday to East Moulsey. Mr. GOSLING showed the results of his experiments as to modifying the focal length of a single-combination achromatic lens by placing lenses of different focal lengths in front. Thus, by using an 8-inch single lens with spectacle lenses of various foci, the following results were obtained: 8-inch single + a 30-inch positive lens = a focus of 6 inches. 8-inch single + a 30-inch negative lens = a focus of 10½ inches. 8-inch single + a 26-inch negative lens = a focus of 12 inches. 8-inch single + a 16-inch negative lens = a focus of 14½ inches. The advantage of the above arrangement was that the effect of an expensive set of casket lenses could be obtained at a cost of only 6*d.* each combination.

North Middlesex Photographic Society.—June 22, Mr. Child Bayley in the chair.—Messrs. MUMMERY and SMITH reported on the outing to Purfleet on Saturday. Mr. H. F. B. Wheeler was unanimously elected a member of the Society. Mr. TILNEY then read an extremely interesting paper entitled

OBSERVATIONS ON PICTURE-MAKING.

By means of sketches, engravings, and lantern slides kindly lent him by Messrs. F. H. Evans, J. Mummery, and S. E. Wall, he showed the reason why a picture pleased, and pointed out what to avoid. He explained the various forms of composition, and traced them out on the screen, criticising the slides as well. There was very little discussion on the paper, Messrs. Johnson, Pither, and MacIntosh making a few remarks, and the CHAIRMAN (Mr. Child Bayley), in tendering his thanks to the lecturer, said that, after the amount of trash and twaddle that had been written and spoken on this subject by incapable persons, it was a genuine pleasure to listen to a trained artist who had so full a knowledge of the subject and the power to impart it. A formal vote of thanks concluded the meeting.

Bradford Photographic Society.—On Saturday, June 20, the members of the Bradford Photographic Society held their first annual competitive excursion to Fountains Abbey, when about twenty-four took advantage of the pleasure-party tickets by the train leaving Bradford at 7.30 a.m., and another detachment (including the President) came on by the afternoon excursion. Altogether nearly 400 exposures were made, one member making forty-four, and another only eight, in cameras in all sizes, from the lordly 12 × 10 down to a quarter of a quarter-plate; in the ingenious little camera made and used by Mr. W. J. Gray. Fountains Abbey is certainly one of the finest ruins in England, and there was ample scope to show what kind of work the members are capable of turning out, and the ruins are so extensive that a full day can be spent most advantageously. One of the Vice-Presidents had thoughtfully provided a commodious yet portable changing tent, which was much appreciated, and we should certainly advise all societies visiting here to provide some such

arrangement and take plenty of plates. The early part of the day being very wet, the time was agreeably occupied in photographing the very fine cloisters, and in this way not much time was lost. The Abbey was taken from all points of view, good and bad, but the wet morning prevented certain portions being photographed under the most suitable conditions, and, there being plenty of wind, the foliage was difficult to manage. Certain accidents or omissions were, of course, inevitable. One gentleman had forgotten his tripod screw, and another had camera, lens, three dozen plates, but had left his tripod at home. The prizes offered are a silver medal, a bronze medal, framed photographs given by a Vice-President; *The Photographic Reference Book* given by another Vice-President; another, Society's certificate. The competitors are allowed until July 20 to get up their prints, but it is not yet decided who is to judge them. The Society is making headway, and the new Committee certainly are justifying their existence, and at almost every meeting two or more new members are added to the number; and, although the weather has been so very sultry, the Monday evenings are better attended than ever.

Photographic Society of Japan.—The Annual Meeting of the above-mentioned Society, for the year ending May, 1896, was held at the College of Science, Imperial University, Tokyo, on Friday, the 22nd inst., at 4.30 p.m. The Secretaries being called on for their report, the following was read:—During the past year the Society has been in a transition state, and has suffered to a certain extent in consequence. Though we have had few meetings and only one field day, there has probably been no year when the individual members have been more active than during the present one. Some of our members have carried on investigations and produced results which deserve a wide publication. The vital question, whether we shall have a home of our own, after having been referred to a competent committee, seems now to be verging towards an affirmative conclusion, and, should the plans, which are already anticipated, be carried out, we are in a way to increase even our old reputation. We are, as it seems, to advance during the present year and coming years by strictly uniting our forces and moving onwards towards better results. The Treasurers were then called on for their report. Mr. A. J. Hare explained that, in the absence of his colleague in the Treasurership, Mr. S. Kajima, jun., who was travelling in Europe, it was not possible to make out a balance-sheet. He explained, however, in general terms the financial condition of the Society. Although all the expenses of the past year came out of money collected by him (Mr. A. J. Hare) as Foreign Treasurer, he had still a balance of cash in the bank of 94·04 dollars, and this though he had to confess to remissness in collecting subscriptions. The balance in the hands of Mr. Kajima at the end of the last financial year had been 235·455 dollars, and must be more now, as it had not been drawn on at all. The officers of the Society then resigned. It was duly proposed, seconded, and carried, that, apart from the Treasurer—the Treasurership being modified on account of alteration of rules—the officers should all be re-elected. It having been announced that Sir Ernest Satow would be willing to act as Vice-President if elected, he was duly proposed, seconded, and unanimously elected a Vice-President of the Society. The question of the Treasurership then came up, and Mr. A. J. Hare, after making some objections, agreed to take the post if elected. He was duly proposed, seconded, and unanimously elected. In accordance with instructions from the Chairman, the following document, a copy of which will be sent to each member of the Society, was read:—"*Proposed Permanent Quarters for the Photographic Society of Japan.*—During the last few years the practice of photography has very greatly increased in this country. The amateur class may be said to have come into existence as an actual body, and it is coming to be recognised that, in the hands of those who have the necessary taste and artistic knowledge, photography is more than a science and a craft—it is a fine art. The greatest difficulty there has been to contend against, up to the present time has risen from the want of means of readily acquiring the necessary technical knowledge, and of having access to publications describing the latest processes, appliances, &c. The Photographic Society of Japan has filled this want so far as possible since the beginning of its existence, but it has been sadly handicapped for want of any permanent quarters. Large numbers of periodicals and books are received by the Society, and many samples of goods and useful pieces of apparatus, but there is no place in which these can be deposited so as to be available to members. In both Europe and America there are photographic societies having permanent quarters. Some of these societies are purely for artistic and scientific purposes, others combine the social element with these, and are of the nature of clubs. The Committee of the Photographic Society of Japan considers that the time has now come when the Society should establish itself in permanent quarters, which shall include dark rooms, enlarging rooms, meeting room, and reading room. In the last-mentioned there will be deposited the leading photographic periodicals of Europe and America, and the beginning of a photographic library which will, it is hoped, in time become extensive." The Committee instructed Mr. Isawa to prepare a design for such a building. There were exhibited during the meeting, by Dr. A. Wood, a very fine enlargement of a laughing girl taken whilst wading at Shiwo shi, the shell-fishing carnival that takes place at Shinagawa every spring; by Mr. T. Konishi, a casket containing a variety of lenses by Goerz; and by Mr. W. K. Burton, a stereoscopic view of the lower end of the ice cave at Shoji, taken, along with Dr. Wood, by magnesium light. The negatives had been made in two hand cameras placed side by side, the lenses being of different type and different focal length, but positive transparencies of the same, and the proper stereoscopic size, had been produced, and the effect was quite good. The prismatic effect of the magnesium light internally reflected and refracted was particularly well rendered, because the stereoscope being a cheap one had lenses not corrected for chromatic aberration. The business part of the meeting having ended, the members and visitors moved into the large hall of the College, when Professor K. Yamakawa, Ph.B., Director of the College, gave a lecture on, and demonstration of, the work of the Röntgen X rays. In spite of the vilest of weather, the attendance was good. The demonstration went off with perfect success, and was of extreme interest. The lecture included a description of original investigations by Professor Yamakawa concerning reflection and refraction of X rays.

Patent News.

THE following applications for Patents were made between June 17 and June 24, 1896:—

SHUTTERS.—No. 13,160. "Improvements in Shutters for Photographic Cameras." J. W. JEYES and A. L. ADAMS.

CAMERAS.—No. 13,284. "Improvements in or relating to Photographic Cameras or Film-exposing Apparatus." Communicated by T. H. Blair. A. J. BOULT.

SHUTTER.—No. 13,324. "An Improved Time and Instantaneous Roller-blind Shutter for Photographic Purposes." H. P. TATTERSALL.

KINETOSCOPY.—No. 13,380. "Photographic Apparatus for Taking Pictures on Films and Projecting Apparatus for Displaying the Pictures on a Photographic Screen." G. RICHARDS.

CAMERAS.—No. 13,425. "An Improvement to Photographic Cameras." J. PEARSE.

KINETOSCOPY.—No. 13,642. "Improvements in or relating to Apparatus for Use in Receiving and Projecting Photographic Images." Complete specification. A. F. PARNALAND.

CAMERAS AND LANTERNS.—No. 13,674. "Improvements in or connected with Cameras and Optical Lanterns." A. WRENCH.

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

THE N. A. P. P. AND THE CONVENTION.

To the EDITORS.

GENTLEMEN,—Allow me space to say, that, as the National Convention is near (July 13), I urge all professional photographers who can spare the time, to rally round Mr. H. P. Robinson, the President for the year, and give him a hearty welcome. His writings from time to time have mostly been for the studio and for professional photographers.

I may say personally I have derived more benefit from his repeated hints as to how to conduct a studio, and manage sitters (the latter a science in itself), than from any other source.

The Convention ought this year to be a reunion of all classes, whether professional or otherwise.

The N.A.P.P., I think, have wisely arranged their outing at the same time, and from a letter I have had from Mr. Drage, the ever-active Convention Secretary, there will, I hope, be a record attendance. Just one hint more, Will members of the profession bring with them goodly specimens of their work, platinotype, and silver portraits, and views, &c.—I am, yours, &c. THOMAS FALL.

9 & 10, *Baker-street, W.*

"PHOTOGRAMS" AGAIN.

To the EDITORS.

GENTLEMEN,—I regret to have to correct an egregious mistake made by one of your contemporaries, which I fear is deliberate, I wont say mischievously deliberate.

The paper to which I allude announces that at the Convention there will be an exhibition of 100 pictorial *photograms*, selected by H. P. Robinson. Now, there is no authority whatever for any such announcement in any document issued by the Council, and I am quite precisely the last person in the world to have anything to do with "photograms," a word which I feel dishonours our art. I complain with great reluctance so near our festive time, but it is just possible that, if I made no protest, my friends would assume that I had accepted the word, and may desert me in disgust and there would be no show. Let me assure them that to this little exhibition nothing but "photographs" will be admitted, and I can only express my regret that they have, either mischievously or ignorantly, been called photograms.

In ordinary life it is not considered very well behaved to "call names;" perhaps it is different in some journalistic announcements.

H. P. ROBINSON.

MR. CHILD BAYLEY ON ART.

To the EDITORS.

GENTLEMEN,—"Cosmos," in last week's BRITISH JOURNAL OF PHOTOGRAPHY, seems a little surprised that I have not replied to the various criticisms upon a paper read by me recently before the Photographic Club. My reason for not troubling you with a letter on the subject was

that so far I had seen little or nothing to reply to. Mr. H. P. Robinson, it is true, stated the following week that I should in the future alter my opinions therein expressed, and be sorry I had put them to paper. It is quite possible, though I trust not probable, that I shall. At any rate, Mr. Robinson has grasped the main idea of my paper to write about the subject one knows most about, and in talking of changes of opinion or of a sudden intellectual right-about-face, he is, of course, quite at home. I, too, "have known similar cases." When Mr. Robinson, however, leaves this familiar ground, and endeavours to argue that the improvement in pictorial photography has taken place since the institution of the Linked Ring, and is therefore due to it, he is dealing more or less with a science, logic, and shows, as indeed he often asserts, that this is not his *forte*. The improvement has taken place since the institution of the Linked Ring, since what I have heard described as the "purification" of another Society, since the affiliation of photographic societies, since the Institution of County Councils, and since the sinking of H.M.S. *Victoria*, and is *therefore*, no doubt, due to these occurrences. As I never said it was or wasn't, this may pass.

If your next correspondent be the talented gentleman whose pictures both in Pall Mall and Piccadilly I have often admired, he is quite consistent in deprecating, by innuendo, the fact that I wrote of matters with which I might be acquainted rather than of societies and exhibitions of which I was entirely ignorant, since he follows out this rule by producing photographic pictures, but writing on the law of averages. If the figures he quotes mean anything, they indicate clearly enough that a member of the Linked Ring stands between three and four hundred times the chance that one of the twenty thousand or so outsiders do, of getting a picture hung at the Salon.

Of other criticism I have little to complain. One gentleman connected with the press compares your humble servant with Mr. Chamberlain and with Lord Salisbury, because, presumably, they and the body they belong to are subject to repeated attacks from the party who recently suffered so heavily at the ballot boxes. The comparison may be flattering, but, when coupled with a column and a half of abuse, which is supposed "to let him off lightly," was surely unnecessary, especially as my paper was considered so dangerous that it had to be diluted by passage through my critic's brain, before in a travestied condition he put it before his readers.

As far as a definite reply is concerned, I would refer those who think it necessary to the paper itself—it contains all the reply I have to make upon points raised by myself, although, of course, no reference will be found in it to opinions saddled on me by my critics to afford them opportunities for discussion. I should like to thank "F. B." for his expression of opinion, as well as several gentlemen who have written direct to myself to a similar effect. Mr. Robinson, I trust, acquits me of "spitefulness" towards himself, with which I have been charged; it would be both unreasonable and ungrateful if I entertained any such feeling, which I don't.

R. Child Bayley.

PHOTOGRAPHING AT THE NATIONAL GALLERY.

To the Editors.

Gentlemen,—*Apropos* of the last paragraph of Mr. Newman's pathetic letter (p. 416 of your last), it may interest your readers to know that the Continental firm in question have announced the issue of an *illustrated* work on the National collection, to which Mr. Eastlake has kindly offered to contribute literary assistance.
